determine screening frequencies for potential comorbid conditions, including tuberculosis, hepatitis B and C, type 2 diabetes, and three sexually transmitted infections (STIs), and to assess demographic and clinical factors associated with screening in the previous 12 months.

**Results.** In the NYC MMP cohort (N = 439), 18% of patients were screened for hepatitis B, 26% for hepatitis C, 37% for type 2 diabetes, 38% for gonorheaa, 41% for chlamydia, 42% for tuberculosis, and 46% for syphilis in the past year. In multivariate analyses, having three or more medical visits with a CD4 count or viral load test during the year was significantly associated with STI screening (OR = 3.84, 95% CI: 1.94, 7.57) and being positive for C screening (OR = 3.45, 95% CI: 1.65, 7.21). Hispanic HIV PWLH were more likely to be screened for hepatitis C (OR = 1.72, 95% CI: 1.05, 2.81) and non-Hispanic Whites were less likely to be screened for type 2 diabetes (OR = 0.30, 95% CI: 0.10, 0.88), compared with non-Hispanic Blacks. Self-reported sex risk behaviors and history of injection drug use were not associated with screening for STI and hepatitis C, respectively.

**Conclusion.** We found a range of screening frequencies for comorbid conditions among PLWH in medical care during 2012, indicating a need for improved integration of HIV care with other clinical services. More frequent HIV care was associated with screening for STI and hepatitis C, possibly due to increased opportunity for testing or care related to the screened-for condition. Notably, we found no relationship between established risk factors for STI and hepatitis C and screening for these conditions.

### 562. The Prevalence of Legionella Species as a Co-pathogen in HIV-Associated Community-Acquired Pneumonia

**Background.** Since the initial description of HIV/AIDS in the USA, cutaneous manifestations have been important in the diagnosis of the disease, and have been frequently associated with immune dysfunction. We sought to describe current dermatologic manifestations in our HIV seropositive veterans who are greater than 50 years of age and compare these to recent reports in HIV seronegative individuals.

**Methods.** This was a retrospective cohort study performed at the South Texas Veterans Health Care System Immunosuppression Clinic. The aim was to review the charts of older HIV-positive veterans with a minimum age of 50, evaluated from January 1, 2015 to December 31, 2015, to investigate any manifestations of cutaneous (HIV) causes hearing loss. Studies have yet to evaluate the impact on QOL. This project evaluates the effect of hearing loss on QOL by HIV status.

**Methods.** The study participants were from the Multicenter AIDS Cohort Study (MACS) and the Women’s Intergeneracy HIV study (WHIS). A total of 248 men and 27 women participated. Pure-tone air conduction thresholds were collected for each ear at frequencies from 250 through 8000 Hz. Pure-tone averages (PTAs) for each ear were calculated as the mean of air conduction thresholds in low frequencies (i.e., 250, 500, 1,000, and 2,000 Hz) and high frequencies (i.e., 3,000, 4,000, 6,000, and 8,000 Hz). QOL (QOL) data were gathered with the Short Form 36 Health Survey and MOS-HIV instrument in the MACS and WHIS, respectively. A median regression analysis was performed to test the association of PTAs with QOL by HIV status.

**Results.** There was no significant association between hearing loss and QOL scores at low and high pure-tone averages in HIV-positive and negative individuals. HIV status, HIV biomarkers and treatment did not change the lack of association of low and high pure-tone averages with poorer QOL.

**Conclusion.** Although we did not find a statistically significant association of hearing loss with QOL by HIV status, testing for hearing loss with aging and recommending treatment may offset any presumed later life decline in QOL.

**Disclosures.** All authors: No reported disclosures.

### 565. Cutaneous Diseases among an Aging HIV Cohort, Receiving Care at an Infectious Diseases/Primary Clinic

**Methods.** This was a retrospective cohort study performed at the South Texas Veterans Health Care System Immunosuppression Clinic. The aim was to review the charts of older HIV-positive veterans with a minimum age of 50, evaluated from January 1, 2015 to December 31, 2015, to investigate any manifestations of cutaneous pathology, HIV and non-HIV-related, analyze the correlation of the dermatological diagnoses by age and CD4 counts. The study participants were from the Multicenter AIDS Cohort Study (MACS) and the Women’s Intergeneracy HIV study (WHIS). A total of 248 men and 27 women participated. Pure-tone air conduction thresholds were collected for each ear at frequencies from 250 through 8000 Hz. Pure-tone averages (PTAs) for each ear were calculated as the mean of air conduction thresholds in low frequencies (i.e., 250, 500, 1,000, and 2,000 Hz) and high frequencies (i.e., 3,000, 4,000, 6,000, and 8,000 Hz). QOL (QOL) data were gathered with the Short Form 36 Health Survey and MOS-HIV instrument in the MACS and WHIS, respectively. A median regression analysis was performed to test the association of PTAs with QOL by HIV status.

**Results.** There was no significant association between hearing loss and QOL scores at low and high pure-tone averages in HIV-positive and negative individuals. HIV status, HIV biomarkers and treatment did not change the lack of association of low and high pure-tone averages with poorer QOL.

**Conclusion.** Although we did not find a statistically significant association of hearing loss with QOL by HIV status, testing for hearing loss with aging and recommending treatment may offset any presumed later life decline in QOL.

### 566. Hearing Loss and Quality of Life Among Human Immunodeficiency Virus (HIV)-Infected and Uninfected Adults

**Methods.** We conducted a retrospective study at Mbarara Regional Referral Hospital (MRRH) in Uganda to evaluate the performance of CRB-65, modified early warning score (MEWS), quick-sepsis-related organ failure assessment (qSOFA), rapid acute physiology score (RAPS), rapid early warning score (REMS), African triage scale (SATS), and shock index (SI) in predicting mortality among HIV-infected patients presenting with sepsis. We included patients admitted with sepsis to MRRH between January 2014 and December 2015 that had an HIV-positive serostatus and at least one valid heart rate, respiratory rate, systolic blood pressure, diastolic blood pressure, temperature, and oxygen saturation. Glasgow comas scale was imputed with the area under the receiver operating curve (AUC) with tenfold cross-validation to assess the performance of each EWS.

**Results.** Of the 193 patients, the median (interquartile range) age was 34 (27, 42) years, 87 (45%) were female and 65 (44%) died. The AUC (95% confidence interval) was 0.53 (0.43, 0.62) for CRB65, 0.53 (0.44, 0.62) for MEWS, 0.57 (0.46, 0.68), for qSOFA, 0.60 (0.51, 0.69) for RAPS, 0.55 (0.46, 0.63) for REMS, 0.53 (0.45, 0.62) for SATS, and 0.54 (0.46, 0.63) for SI.

**Conclusion.** The ability of EWS to predict mortality in an HIV-infected patient population with sepsis in Uganda was poor. EWS used in SSA should be derived from African patient populations and adjust for HIV serostatus.

### 567. Performance of Early-Warning Scores in Predicting Mortality in an HIV-Infected Population with Sepsis in Uganda

**Session:** 63. HIV Clinical Care and Outcomes

**Thursday, October 5, 2017: 12:30 PM**

**Background.** Research has established that human immunodeficiency virus (HIV) causes hearing loss. Studies have yet to evaluate the impact on QOL. This project evaluates the effect of hearing loss on QOL by HIV status.

**Methods.** The study participants were from the Multicenter AIDS Cohort Study (MACS) and the Women’s Intergeneracy HIV study (WHIS). A total of 248 men and 27 women participated. Pure-tone air conduction thresholds were collected for each ear at frequencies from 250 through 8000 Hz. Pure-tone averages (PTAs) for each ear were calculated as the mean of air conduction thresholds in low frequencies (i.e., 250, 500, 1,000, and 2,000 Hz) and high frequencies (i.e., 3,000, 4,000, 6,000, and 8,000 Hz). QOL (QOL) data were gathered with the Short Form 36 Health Survey and MOS-HIV instrument in the MACS and WHIS, respectively. A median regression analysis was performed to test the association of PTAs with QOL by HIV status.

**Results.** There was no significant association between hearing loss and QOL scores at low and high pure-tone averages in HIV-positive and negative individuals. HIV status, HIV biomarkers and treatment did not change the lack of association of low and high pure-tone averages with poorer QOL.

**Conclusion.** Although we did not find a statistically significant association of hearing loss with QOL by HIV status, testing for hearing loss with aging and recommending treatment may offset any presumed later life decline in QOL.

566. When Viral Suppression Is Not Enough: Clinical Characteristics of HIV Infected Patients with Poor Immune Recovery
Siddhi Mankame, MD1; Negin Niknam, MD, MD2; Mohammed Elleyke, MBBS3; Rebecca Schwartz, PhD1; Rehana Rasul, MA, MPH1; Bruce Hirsch, MD 3 and Joseph McGowan, MD3; Infectious Diseases, Hofstra Northwell School of Medicine, Manhasset, New York; Infectious Disease, Hofstra University, North Shore - LIJ Hospital, Manhasset, New York; Infectious Diseases, NYC Department of Health, New York, New York; 1Department of Occupational Medicine, Epidemiology and Prevention, Northwell Health, Hofstra Northwell School of Medicine, Manhasset, New York; Infectious Diseases, Northwell Health, Feinstein Institute of Medical Research, Manhasset, New York; Infectious Disease, Hofstra Northwell School of Medicine, Manhasset, New York.

Session: 63. HIV Clinical Care and Outcomes
Thursday, October 5, 2017: 12:30 PM

Background. The use of combination antiretroviral therapy (ARTV) has made it possible to halt HIV replication, achieve CD4+ recovery and immune reconstitution. Some patients with long-term viral suppression never adequately recover their CD4+ count and manifest increased mortality. Age, CD4+ nadir, Hepatitis C infection have been associated with incomplete immune recovery. By matching for age, gender, and CD4 nadir, we aim to elucidate the role of clinical factors in virally suppressed patients with suboptimal CD4 recovery.

Methods. Retrospective record review of patients with CD4+ >200 (Cases) and CD4+ <500 (Controls) with over 2 years of viral suppression (viral load <200) on ARTV for the same duration, was conducted. One case was matched to 2 controls by age, gender and CD4 nadir. Associations between variables were assessed using univariable exact conditional logistic regressions.

Results. Of the 1265 charts reviewed, 13 cases were identified. A unit higher BMI was significantly associated with a 13% lower odds of having low CD4 (P = 0.04). Higher hemoglobin A1c (A1c) was associated with 82% lower odds of having low CD4 (P = 0.02). Other non-significant comparisons include ethnicity; 35% cases were Hispanic vs. 16% controls. Gastrointestinal (GI) symptoms were more common in the cases (83% vs. 50%), as was lymphopenopath (LAD) (36.4% vs. 25%). Mean years since diagnosis was longer in cases (19.2 vs. 16.7) despite the duration of ARTV being longer in controls. Mean number of comorbidities was higher in cases (3.17 vs. 2.75). Controls had much lower use (45.8% vs. 25%).

Conclusion. Incomplete CD4 recovery was significantly associated with lower BMI, suggesting that despite viral suppression, these patients are vulnerable to metabolic issues that affect uncontrolled HIV patients. We hypothesize that rapid control of HIV in this urban population was associated with weight gain and note that the BMI in controls was in the obesity range. Statin use may play a protective role in the controls, perhaps due to its anti-inflammatory properties. Trends in GI symptoms, LAD, number of comorbidities, albeit not statistically significant, seem to be important. Due to small sample size, this study was underpowered to fully assess the effect of these factors. Thus, this study should be considered exploratory.

Session: 63. HIV Clinical Care and Outcomes
Thursday, October 5, 2017: 12:30 PM

Background. Chronic pain in HIV infected patients is common in the ambulatory setting, the majority of which is musculoskeletal (MSK). Addressing patient’s pain is essential but physicians often fail to adequately manage MSK pain. Additionally, HIV patients with chronic non-cancer pain (CNCP) have a 2-fold increase in the risk of opioid misuse compared with the general population. We sought to determine the extent of pain complaints and opioid prescriptions in our HIV clinic as well as assess the comfort and ability of our residents to develop a comprehensive pain management plan.

Methods. We completed a chart review of all patients seen by our Internal Medicine (IM) residents in the HIV primary care in Detroit, MI from 01/2017-05/2017 and collected demographic and pain-related data. We also surveyed IM residents assigned to HIV primary care clinic on their knowledge and comfort developing management plans for CNCP. IRB waiver was obtained.

Results. A total of 249 HIV infected patients were seen from January 2017 to May 2017. Forty-one of 249 (16%) of patients were identified as having a CNCP and of these patients, all were treated with opioids. MSK symptoms encountered were osteoarthritis (28/41 (68%) of the total complaints. This included back pain (n = 20), lower extremity pain (n = 10), and upper extremity pain (n = 2). Only 5/41 (17%) patients were prescribed physical therapy for their pain complaints. Fifteen of 20 (75%) IM residents responded to a survey on their comfort and knowledge in treating CNCP. Ninety percent of the 15 (0%) felt completely comfortable developing a plan for CNCP. 2/15 (13%) felt their examination skills were adequate in assessing MSK symptoms in patients with CNCP. 12/15 (80%) felt working in collaboration with a physical therapist (PT) would be beneficial in developing effective treatment plans and 10/15 (67%) thought working in collaboration with a PT would help further develop their examination skills.

Conclusion. A survey of our IM residents has found gaps in both knowledge and comfort in CNCP pain management and high levels of opioid prescriptions in our HIV primary care clinic. Here we provide evidence that IM residents require additional training in treating CNCP in HIV patients and are interested in multidisciplinary approaches to development of non-pharmacologic treatment plans for HIV infected patients with CNCP.
