Octet baryon magnetic moments from QCD sum rules

Lai Wang and Frank X. Lee

Physics Department, The George Washington University, Washington, DC 20052, USA

A comprehensive study is made for the magnetic moments of octet baryons in the method of QCD sum rules. A complete set of QCD sum rules is derived using the external field method and generalized interpolating fields. For each member, three sum rules are constructed from three independent tensor structures. They are analyzed in conjunction with the corresponding mass sum rules. The performance of each of the sum rules is examined using the criteria of OPE convergence and ground-state dominance, along with the role of the transitions in intermediate states. Individual contributions from the u, d and s quarks are isolated and their implications in the underlying dynamics are explored. Valid sum rules are identified and their predictions are obtained. The results are compared with experiment and previous calculations.

I. INTRODUCTION

The QCD sum rule method is a nonperturbative analytic formalism firmly entrenched in QCD with minimal modeling. The field remains active judging by the 3000 and growing references to the seminal paper of Shifman, Vainshtein and Zakharov [1] that introduced the method. The approach provides a general way of linking hadron phenomenology with the interactions of quarks and gluons via only a few parameters: the QCD vacuum condensates and susceptibilities. The studies give an unique perspective on how the properties of hadrons arise from nonperturbative interactions in the QCD vacuum and how QCD works in this context. It has been successfully applied in almost every aspect of strong-interaction physics.

Calculations of the magnetic moment were carried out soon after the method was introduced for the proton, neutron \(\hat{2}\ \hat{1}\ \hat{4}\) and hyperons \(\hat{2}\ \hat{1}\ \hat{8}\) in the external field method. In this method, a static magnetic field is introduced that couples to the quarks and polars the QCD vacuum. Magnetic moments can be extracted from the linear response to this field. The results of the studies validated the external field method as a way of probing hadron properties other than the mass, such as magnetic moments, form factors, axial charge, isospin-breakings. Later, a more systematic study was made for the magnetic moments of octet baryons \(\hat{2}\ \hat{1}\ \hat{4}\ \hat{8}\). Calculations were also carried out for decuplet baryons \(\hat{3}\ \hat{10}\ \hat{11}\ \hat{12}\) and the rho meson \(\hat{13}\). There are other studies of magnetic moments using the light-cone QCD sum rule method \(\hat{14}\ \hat{15}\ \hat{16}\ \hat{17}\) which will not discuss here.

In this work, we carry out a comprehensive, independent calculation of the magnetic moments of the octet baryons in the external field method. It can be considered as an update over the previous calculations \(\hat{3}\ \hat{10}\ \hat{11}\) which were done more than 20 years ago. There are a number of things we do differently. First, we employ generalized interpolating fields which allow us to use the optimal mixing of interpolating fields to achieve the best match. Second, we derive a new, complete set of QCD sum rules at all three tensor structures and analyze all of them. The previous sum rules, which were mostly limited to one of the tensor structures, correspond to a special case of the mixing in our sum rules. In this way, we provide an independent check of the previous sum rules. Third, we perform a Monte-Carlo analysis which has become standard nowadays. The advantage of such an analysis is explained later. Fourth, we use a different procedure to extract the magnetic moments and to treat the transition terms in the intermediate states. Our results show that these transitions cannot be simply ignored. Fifth, we isolate the individual quark contributions to the magnetic moments and discuss their implications in the underlying quark-gluon dynamics in the baryons.

The paper is organized as follows. In Section II the method of QCD sum rules is introduced. Using the interpolating fields for the octet baryons, master formula are calculated. Then both the phenomenological representation and QCD side are derived. Section III will list the sum rules we derived for the octet baryon family, followed by the analysis to extract the magnetic moments in Section IV. Section V summarizes the results and gives a comparison of our results with experiment and previous calculation, followed by an in-depth discussion of our findings. Our conclusions are given in Section VI.

II. METHOD

The starting point is the time-ordered correlation function in the QCD vacuum in the presence of a constant background electromagnetic field \(F_{\mu\nu}\):

\[
\Pi(p) = i \int d^4 x \ e^{ipx} \langle 0 | T \{ \eta(x) \bar{\eta}(0) \} | 0 \rangle_F. \quad (1)
\]

The QCD sum rule approach is to evaluate this correlation at two different levels. On the quark level, it describes a hadron as quarks and gluons interacting in the QCD vacuum. On the phenomenological level, it is saturated by a tower of hadronic intermediate states.
with the same quantum numbers. This way, a connection can be established between a description in terms of hadronic degrees of freedom and one based on the underlying quark and gluon degrees of freedom governed by QCD. Here $\eta$ is the interpolating field (or hadron current) with the quantum numbers of the hadron under consideration. The subscript $F$ means that the correlation function is to be evaluated with an electromagnetic interaction term added to the QCD Lagrangian:

$$\mathcal{L}_I = -A_\mu J^\mu,$$

where $A_\mu$ is the external electromagnetic potential and $J^\mu = e_q \bar{q} \gamma^\mu q$ is the quark electromagnetic current.

Since the external field can be made arbitrarily small, one can expand the correlation function

$$\Pi(p) = \Pi^{(0)}(p) + \Pi^{(1)}(p) + \cdots,$$

where $\Pi^{(0)}(p)$ is the correlation function in the absence of the field, and gives rise to the mass sum rules of the baryons. The magnetic moments will be extracted from the QCD sum rules obtained from the linear response function $\Pi^{(1)} (p)$.

The action of the external electromagnetic field is two-fold: it couples directly to the quarks in the baryon interpolating fields, and it also polarizes the QCD vacuum. The latter can be described by introducing new parameters called vacuum susceptibilities.

The interpolating field is constructed from quark fields with the quantum number of baryon under consideration and it is not unique. We consider a linear combination of the two standard local interpolating fields. They read for the baryon octet family:

$$\eta^{(uud)} = -2e^{abc}[(u^{aT} C_\gamma \gamma^5 d^b) u^c + \beta(u^{aT} C d^b) \gamma^5 u^c],$$

$$\eta^{(ddu)} = -2e^{abc}[(d^{aT} C_\gamma \gamma^5 u^b) d^c + \beta(d^{aT} C u^b) \gamma^5 d^c],$$

$$\eta^{(uds)} = -2\sqrt{\frac{1}{3}}e^{abc}[2(u^{aT} C_\gamma \gamma^5 d^b) s^c + (u^{aT} C_\gamma \gamma^5 s^b) d^c - (d^{aT} C_\gamma \gamma^5 s^b) u^c + \beta(2(u^{aT} C d^b) \gamma^5 s^c + (u^{aT} C s^b) \gamma^5 d^c - (d^{aT} C s^b) \gamma^5 u^c)],$$

$$\eta^{(\Sigma^-)}(dds) = -2e^{abc}[(d^{aT} C_\gamma \gamma^5 u^b) d^c + \beta(d^{aT} C s^b) \gamma^5 d^c],$$

$$\eta^{(\Xi^0)}(uds) = -\sqrt{2}e^{abc}[(u^{aT} C_\gamma \gamma^5 s^b) d^c + (d^{aT} C_\gamma \gamma^5 s^b) u^c + \beta((u^{aT} C s^b) \gamma^5 d^c + (d^{aT} C s^b) \gamma^5 u^c)],$$

$$\eta^{(\Xi^-)}(usu) = -2e^{abc}[(u^{aT} C_\gamma \gamma^5 s^b) u^c + \beta(u^{aT} C s^b) \gamma^5 u^c],$$

$$\eta^{(\Xi^-)}(ssu) = -2e^{abc}[(s^{aT} C_\gamma \gamma^5 u^b) s^c + \beta(s^{aT} C d^b) \gamma^5 s^c],$$

$$\eta^{(\Xi^-)}(sds) = -2e^{abc}[(s^{aT} C_\gamma \gamma^5 u^b) d^c + (d^{aT} C_\gamma \gamma^5 u^b) s^c + \beta(s^{aT} C u^b) \gamma^5 s^c].$$

Here $u$ and $d$ are up-quark and down-quark field operators, $C$ is the charge conjugation operator, the superscript $T$ means transpose, and $\epsilon_{abc}$ makes it color-singlet. The normalization factors are chosen so that correlation functions of these interpolating fields coincide with each other under SU(3)-flavor symmetry. The real parameter $\beta$ allows for the mixture of the two independent currents. The choice advocated by Ioffe [18] and often used in QCD sum rules studies corresponds to $\beta = -1$. We will take advantage of this freedom to achieve optimal matching in the sum rule analysis.

### A. Phenomenological Representation

We start with the structure of the two-point correlation function in the presence of the electromagnetic vertex to first order

$$\Pi(p) = \int d^4x \epsilon^{ipx} < 0|\eta(x)[-i \int d^4 y A_\mu(y) J^\mu(y) ]|\eta(0)|0 >.$$

Inserting two complete sets of physical intermediate states, we restrict our attention only to the positive energy ones and write

$$\Pi(p) = \int d^4x d^4y \frac{d^4k}{(2\pi)^4} \frac{d^4k}{(2\pi)^4} \sum_{N} \sum_{N'} \sum_{s} \sum_{s'} \sum_{k^2 - M^2_N - i\epsilon} \sum_{k^2 - M^2_{N'} - i\epsilon} \epsilon^{ipx} A_\mu(y) < 0|\eta(x)|N'k's' > < N'k's'|J^\mu(y)|Nks > < Nks|\eta(0)|0 >.$$

We can use the translation invariance to express $\eta(x)$ in terms of $\eta(0)$

$$< 0|\eta(x)|N'k's' > = < 0|\eta(0)|N'k's' > e^{-ik'x}.$$

The interpolating field excites (or annihilates) the ground state as well as the excited states of the baryon from the QCD vacuum. The ability to do so is described by a phenomenological parameter $\lambda_N$ (called current coupling or pole residue), defined by the overlap for the ground state

$$< 0|\eta(0)|Nks > = \lambda_N u(k,s),$$

where $u$ is the Dirac spinor.

Translation invariance on $J^\mu(y)$ gives

$$< N'k's'|J^\mu(y)|Nks > = e^{iqy} < N'k's'|J^\mu(0)|Nks >,$$

where $q$ is the momentum transfer.
where $q = k' - k$ is the momentum transfer and $Q^2 = -q^2$.

The matrix element of the electromagnetic current has the general form

$$<k's' | J_\mu(0) | ks > = \bar{u}(k', s') [F_1(Q^2) \gamma_\mu + F_2(Q^2)i\sigma^{\mu\nu}\frac{q^\nu}{2M_N}] u(k, s),$$

(10)

where the Dirac form factors $F_1$ and $F_2$ are related to the Sachs form factors by

$$G_E(Q^2) = F_1(Q^2) - \frac{Q^2}{(2M_N)^2} F_2(Q^2)$$
$$G_M(Q^2) = F_1(Q^2) + F_2(Q^2).$$

(11)

At $Q^2 = 0$, $F_1(0) = 1$, $F_2(0) = \mu^a$ which is the anomalous magnetic moment, and $G_M(0) = F_1(0) + F_2(0) = \mu$ which is the total magnetic moment.

Writing out explicitly only the contribution of the ground-state nucleon and denoting the excited state contribution by ESC, we have

$$\Pi(p) = -\lambda_1^3 \int d^4x d^4y d^4k' d^4q \left[ k^2 - M_N^2 - i\varepsilon \right]^{-1} \left[ (q - k')^2 - M_N^2 - i\varepsilon \right]^{-1} A_\mu(y) e^{i(p-k')x}$$
$$e^{iqy} \sum_s u(k', s') \bar{u}(k', s') [F_1(Q^2) \gamma_\mu + F_2(Q^2)i\sigma^{\mu\nu}\frac{q^\nu}{2M_N}] \sum_s u(k, s) \bar{u}(k, s) + ESC.$$ 

(12)

The spin sums are of the form

$$\sum_s u(k, s) \bar{u}(k, s) = \hat{k} + M_N.$$ 

(13)

QCD sum rule calculations are most conveniently done in the fixed-point gauge. For electromagnetic field, it is defined by $x_\mu A_\mu(x) = 0$. In this gauge, the electromagnetic potential is given by

$$A_\mu(y) = -\frac{1}{2} F_{\mu\nu} y^\nu.$$ 

(14)

Changing variables from $k$ to $q = k' - k$, then $d^4k = -d^4q$, we have

$$\Pi(p) = \frac{\lambda_1^3}{2} F_{\mu\nu} \int d^4x d^4y d^4k' d^4q \left[ k^2 - M_N^2 - i\varepsilon \right]^{-1} \left[ (q - k')^2 - M_N^2 - i\varepsilon \right]^{-1}$$
$$e^{i(q-k')x} \left( -i \frac{\partial}{\partial q^\mu} e^{iqy} \right) (\hat{p} + M_N) [F_1(Q^2) \gamma_\mu + F_2(Q^2)i\sigma^{\mu\nu}\frac{q^\nu}{2M_N}] (\hat{k} - \hat{q} + M_N) + ESC.$$ 

(15)

Integrating over $x$, we get a delta function

$$\int d^4x \frac{1}{(2\pi)^4} e^{i(p-k')x} = \delta^4(p-k').$$ 

(16)

Integrating $\partial/\partial q_\mu$, by parts, then doing $\int d^4y$, we can get another delta function $\delta(q)$. Since we have a $\delta(q)$, when doing $\partial/\partial q_\mu$ only terms linear in $q_\mu$ contribute. We have $F_1(Q^2)|_{q=0} = 1$, $F_2(Q^2)|_{q=0} = \mu^a = \mu - 1$, and $\partial/\partial q_\mu F_{2,2}(Q^2)|_{q=0} = 0$, so derivatives of the structure functions do not enter. Finally, we arrive at

$$\Pi(p) = \frac{\lambda_1^3}{2} F_{\mu\nu} [p^2 - M_N^2 - i\varepsilon]^{-2} (\hat{p} + M_N) \left( i \frac{4M_N - 1}{2M_N} \sigma^{\mu\nu} (\hat{p} + M_N) + i\sigma^{\mu\nu} - (p^\mu p^\nu - p^\nu p^\mu) (\hat{p} + M_N) [p^2 - M_N^2 - i\varepsilon]^{-1} \right] + ESC.$$ 

(17)

Examination of its tensor structure reveals that its has 3 independent combinations: $F^{\mu\nu} (\hat{p} \sigma_{\mu\nu} + \sigma_{\mu\nu} \hat{p})$, $F^{\mu\nu} i(p_\nu \gamma_\mu - p_\mu \gamma_\nu) \hat{p}$ and $F^{\mu\nu} \sigma_{\mu\nu}$. The momentum-space correlation function in the above equation can be written in terms of these three structures

$$\Pi(p) = \frac{\lambda_1^3}{4} F_{\mu\nu} \left( [\sigma^{\mu\nu}](2M_N \mu N) + \frac{4M_N - 1}{2M_N} (p^2 - M_N^2) + \mu N [\hat{p} \sigma^{\mu\nu} + \sigma^{\mu\nu} \hat{p}] ight.$$ 
$$+ \frac{2(4M_N - 1)}{M_N} [i(p^\mu \gamma^\nu - p^\nu \gamma^\mu)] \hat{p}] + ESC,$$ 

(18)

where we have used the following identities

$$(\hat{p} + M_N) \sigma^{\mu\nu} = M_N \sigma^{\mu\nu} + \frac{1}{2} (\hat{p} \sigma^{\mu\nu} + \sigma^{\mu\nu} \hat{p}) + i(p^\mu \gamma^\nu - p^\nu \gamma^\mu),$$
$$(\hat{p} + M_N) \sigma^{\mu\nu} (\hat{p} + M_N) = \sigma^{\mu\nu} (p^2 + M_N^2) + M_N (\hat{p} \sigma^{\mu\nu} + \sigma^{\mu\nu} \hat{p}) + 2i(p^\mu \gamma^\nu - p^\nu \gamma^\mu) \hat{p},$$
$$(\hat{p} + M_N) (p^\mu \gamma^\nu - p^\nu \gamma^\mu) (\hat{p} + M_N) = -(p^2 - M_N^2)(p^\mu \gamma^\nu - p^\nu \gamma^\mu).$$

(19)
Upon Borel transform the ground state takes the form

\[ \hat{B}[f(p^2)] = \lim_{-p^2, n \to \infty} \frac{1}{n!} (-p^2)^{n+1} \frac{d^n f(p^2)}{dp^2}. \]  

(20)

Next step is to perform the Borel transform defined by

\[ \hat{B}[\Pi(p)] = -\frac{\lambda_N^2}{M_N^2} e^{-M_N^2/M^2} \left\{ \frac{1}{M_N} (2M_N^2 \mu_N - M^2 (\mu_N - 1)) [F_{\mu\nu}\sigma^{\mu\nu}] + \mu_N [F_{\mu
u} (p\sigma^{\mu\nu} + \sigma^{\mu\nu} \hat{\rho})] + \frac{2(\mu_N - 1)}{M_N^2} [F_{\mu\nu} i(p^{\mu} \gamma^{\nu} - p^{\nu} \gamma^{\mu}) \hat{\rho}] \right\}, \]  

(21)

where \( M \) is the Borel mass, not to be confused with the nucleon mass \( M_N \).

Here we must treat the excited states with care. For a generic invariant function, the pole structure can be written as

\[ \frac{C^2_{N,\rightarrow N}}{(p^2 - M^2)^2} + \sum_{N'} \frac{C^2_{N,\rightarrow N'}}{(p^2 - M^2_{N'})(p^2 - M^2_{N'})} + \sum_{N',N''} \frac{C^2_{N,\rightarrow N',N''}}{(p^2 - M^2_{N'})^2}, \]  

(22)

where \( C_{N,\rightarrow N}, C_{N,\rightarrow N'} \) and \( C_{N',\rightarrow N''} \) are constants. The first term is the ground state pole which contains the desired magnetic moment \( \mu_N \). The second term represents the non-diagonal transitions between the ground state and the excited states caused by the external field. The third term is pure excited state contributions. These different contributions can be represented by the diagrams in Fig. 1. Upon Borel transform, it takes the form

\[ \frac{\lambda_N^2 \mu_N}{M^2} e^{-M_N^2/M^2} + e^{-M_N^2/M^2} \left[ \sum_{N'} \frac{C^2_{N,\rightarrow N'}}{M^2_{N'} - M^2} \left( 1 - e^{-M^2_{N'} + M^2}/M^2 \right) \right] + \sum_{N',N''} \frac{C^2_{N,\rightarrow N',N''}}{M^2_{N'} - M^2} e^{-M^2_{N'}/M^2}. \]  

(23)

The important point is that the transitions give rise to a contribution that is not exponentially suppressed relative to the ground state. This is a general feature of the external-field technique. The strength of such transitions at each structure is a priori unknown and is an additional source of contamination in the determination of the magnetic moment \( \mu_N \). The standard treatment of the transitions is to approximate the quantity in the square brackets by a constant, which is to be extracted from the sum rule along with the ground state property of interest. Inclusion of such contributions is necessary for the correct extraction of the magnetic moments. The pure excited state contributions are exponentially suppressed relative to the ground state and can be modeled in the usual way by introducing a continuum model and threshold parameter.

**B. Calculation of the QCD Side**

We start by contracting out the quark pairs in Eq. 1 using Wick’s theorem, resulting in the so-called master formula in terms of quark propagators. The master formula for the proton (with uud quark content) is

\[ \langle \Omega | T\{\bar{N}(x) \bar{N}^c(0)\} | \Omega \rangle = -4 e^{abc} e^{a'b'c'} \{ \]  

\[ + S_{ua'}^c \gamma_5 C_{d'}^c T C_{\gamma_5} S_{u'}^{b'b'} + S_{ua'}^c \text{Tr}(C_{d'}^c T C_{\gamma_5} S_{u'}^{b'b'} \gamma_5) \]  

\[ + \beta \gamma_5 S_{ua'}^{c'} \gamma_5 C_{d'}^c T C_{u}^{b'b'} + \beta \gamma_5 S_{ua'}^{c'} \text{Tr}(C_{d'}^c T C_{\gamma_5} S_{u'}^{b'b'} \gamma_5) \]  

\[ + \beta S_{ud'}^c C_{d'}^c T C_{\gamma_5} S_{u}^{b'b'} \gamma_5 + \beta S_{ud'}^c \gamma_5 \text{Tr}(C_{d'}^c T C_{\gamma_5} S_{u'}^{b'b'} \gamma_5) \]  

\[ + \beta^2 S_{ud'}^c C_{d'}^c T C_{\gamma_5} S_{u}^{b'b'} + \beta^2 \gamma_5 S_{ua'}^{c'} \text{Tr}(C_{d'}^c T C_{\gamma_5} S_{u'}^{b'b'} \gamma_5) \} \].  

(24)
The master formula for neutron (with ddu quark content) can be obtained by exchanging the d quark with a u quark from Eq. (27). By replacing the d quark with a s quark, one can get the master formula for Σ+(with uss quark content). While the master formula for Σ− (with uus quark content) can be obtained by replacing the u quark with a d quark from Σ+ master formula. By exchanging the u quarks and s quarks in Σ+ master formula, the master formula for Ξ0 (with ssu quark content) can be obtained. Likewise, by replacing the u quark with a d quark, one can get the master formula for Ξ+ (with ssd quark content).

The master formulae for Σ0 and Λ (uds quark content) have a more complicated structure. They can be written in a combined way as

\[
(\Omega | T \{ \eta(x) \hat{q}(0) \} | \Omega) = -f \epsilon^{abc} \epsilon_{a'b'c'} \left\{ f_{1}f_{2}s_{a}^{cc} \gamma_{s}^{C_{s}c_{c}T} C_{\gamma}^{5}S_{u}^{bb'} + f_{1}f_{3}s_{a}^{aa'} \gamma_{s}^{C_{s}c_{c}T} C_{\gamma}^{5}S_{u}^{bb'} + f_{2}f_{3}S_{u}^{cb'} \gamma_{s}^{C_{s}c_{c}T} C_{\gamma}^{5}S_{u}^{bb'} \right.
\]

where the various factors are: for Σ0 content). While the master formula for Σ+ (with uus quark content) can be obtained by replacing the u quark with a d quark from Σ+ master formula. By exchanging the u quarks and s quarks in Σ+ master formula, the master formula for Ξ0 (with ssu quark content) can be obtained. Likewise, by replacing the u quark with a d quark, one can get the master formula for Ξ+ (with ssd quark content).

The master formulae for Σ0 and Λ (uds quark content) have a more complicated structure. They can be written in a combined way as

\[
\langle \Omega | T \{ \eta(x) \hat{q}(0) \} | \Omega \rangle = -f \epsilon^{abc} \epsilon_{a'b'c'} \left\{ f_{1}f_{2}s_{a}^{cc} \gamma_{s}^{C_{s}c_{c}T} C_{\gamma}^{5}S_{u}^{bb'} + f_{1}f_{3}s_{a}^{aa'} \gamma_{s}^{C_{s}c_{c}T} C_{\gamma}^{5}S_{u}^{bb'} + f_{2}f_{3}S_{u}^{cb'} \gamma_{s}^{C_{s}c_{c}T} C_{\gamma}^{5}S_{u}^{bb'} \right.
\]

where the various factors are: for Σ0, f = 2/3, f1 = 0, f2 = 1, f3 = 1, f4 = 0, f5 = 1, f6 = 1; and for Λ, f = 2, f1 = 2, f2 = 1, f3 = -1, f4 = 2, f5 = 1, f6 = -1.

In the above equations,

\[
S_{q}^{ab}(x, 0; F) = \langle 0 | T \{ q^{a}(x) \hat{q}^{b}(0) \} | 0 \rangle_{F}, \quad q = u, d, s,
\]

is the fully interacting quark propagator in the presence of the electromagnetic field. To first order in \( F_{\mu\nu} \) and \( m_{q} \) (assume \( m_{u} = m_{d} = 0, m_{s} \neq 0 \)), and order \( x^{2} \), it is given by the operator product expansion (OPE) [3 6 7]:

\[
S_{q}^{ab}(x, 0; Z) = \frac{i x^{2}}{2 \pi^{2} x^{4}} \delta^{ab} - \frac{m_{q}}{4 \pi^{2} x^{2}} \delta^{ab} + \frac{1}{12} \langle \bar{q}q \rangle \delta^{ab} + \frac{i m_{q}}{48} \langle \bar{q}q \rangle \hat{x} \delta^{ab}
\]

(26)
We use the convention $\epsilon^{0123} = +1$ in this work.

In addition to the standard vacuum condensates, the vacuum susceptibilities induced by the external field are defined by

$$
\langle \bar{q} \gamma_\mu q \rangle_F \equiv e_q \chi (\bar{q} q) F_{\mu\nu},
\langle \bar{q} G_{\mu\nu} q \rangle_F \equiv e_q \kappa (\bar{q} q) F_{\mu\nu},
\langle \bar{q} g_\epsilon^{\mu\nu\rho\sigma} G^\rho\lambda q \rangle_F \equiv i e_q \xi (\bar{q} q) F_{\mu\nu}.
$$

(28)

Note that $\chi$ has the dimension of GeV$^{-2}$, while $\kappa$ and $\xi$ are dimensionless.

With the above elements in hand, it is straightforward to evaluate the correlation function by substituting the quark propagator into the various master formulae. We keep terms to first order in the external field and in the strange quark mass. Terms up to dimension 8 are considered. The algebra is extremely tedious. Each term in the master formula is a product of three copies of the quark propagator. There are hundreds of such terms over various color permutations. The calculation can be organized by diagrams (similar to Feynmann diagrams) in Fig. 2 and Fig. 3. Note that each diagram is only generic and all possible color permutations are understood. The QCD side has the same tensor structure as the phenomenological side and the results can be organized according to the same 3 independent structures.

III. QCD SUM RULES

Once we have both the QCD side (LHS) and the phenomenological side (RHS), we can derive the sum rules by matching both sides. Since there are three independent tensor structures, three sum rules can be constructed. We denote these tensor structures by the following shorthand notation

$$
\text{WE}_1 = F^{\mu\nu} (\bar{p} \sigma_{\mu\nu} + \sigma_{\mu\nu} \bar{p}),
\text{WO}_1 = F^{\mu\nu} \sigma_{\mu\nu},
\text{WO}_2 = F^{\mu\nu} i (p_\mu \gamma_\nu - p_\nu \gamma_\mu) \bar{p}
$$

(29)

(30)

(31)

The sum rule from WE$_1$ involves only dimension-even condensates, so we call this sum rule chiral-even. The sum rule from both WO$_1$ and WO$_2$ involves only dimension-odd condensates, so we call them chiral-odd. Note that in previous works $\text{WO}_1$ and $\text{WO}_2$ the dimension of the tensor structures, rather than the dimension of the condensates, was used to refer to the sum rules. The two names are opposite.

Now we are ready to collect all of the QCD sum rules. At the structure WE$_1$, all of the sum rules can be expressed in the following form

$$
c_1 L^{-4/9} E_2(w) M^4 + c_2 m_s \alpha L^{-26/27} E_1(w) M^2 + c_3 \alpha^2 L^{-4/27} E_0(w) + c_4 b L^{-4/9} E_0(w) + (c_5 + c_6) m_s a L^{-4/9} E_0(w) + (c_7 + c_8) a^2 L^{-18/27} E_0(w) + c_{10} m_s a^2 L^{-26/27} E_0(w) + \chi^{\lambda_7}_2 \langle \frac{\mu}{M^2} + A \rangle e^{-M^2/2M^2}
$$

(32)

where the coefficients differ from member to member. The quark condensate, gluon condensate, and the mixed condensate are

$$
a = -(2\pi)^2 \langle \bar{u} u \rangle, \quad b = (g_5^2 G^2), \quad \langle \bar{u} g_\epsilon \sigma \cdot G u \rangle = -m_0^2 \langle \bar{u} u \rangle.
$$

(33)

The quark charge factors $e_q$ are given in units of electric charge

$$
e_u = 2/3, \quad e_d = -1/3, \quad e_s = -1/3.
$$

(34)

Note that we choose to keep the quark charge factors explicit in the sum rules. The advantage is that it can facilitate the study of individual quark contribution to the magnetic moments. The parameters $f$ and $\phi$ account for the flavor-symmetry breaking of the strange quark in the condensates and susceptibilities:

$$
f = \frac{\langle ss \rangle}{\langle \bar{u} u \rangle}, \quad \langle \bar{u} g_\epsilon \sigma \cdot G s \rangle, \quad \phi = \frac{\chi_s}{\chi} = \frac{\kappa_s}{\kappa} = \frac{\xi_s}{\xi}.
$$

(35)

The anomalous dimension corrections of the interpolating fields and the various operators are taken into account in the leading logarithmic approximation via the factor

$$
L^\gamma = \left[ \frac{\alpha_s (\mu^2)}{\alpha_s (M^2)} \right]^\gamma = \left[ \frac{\ln(M^2/\Lambda_{QCD}^2)}{\ln(\mu^2/\Lambda_{QCD}^2)} \right]^\gamma,
$$

(36)

where $\mu = 500$ MeV is the renormalization scale and $\Lambda_{QCD}$ is the QCD scale parameter. As usual, the pure excited state contributions are modeled using terms on the OPE side surviving $M^2 \to \infty$ under the assumption of duality, and are represented by the factors

$$
E_n(w) = 1 - e^{-w^2/M^2} \sum_n \frac{(w^2/M^2)^n}{n!},
$$

(37)

where $w$ is an effective continuum threshold and it is in principle different for different sum rules and we will treat it as a free parameter in the analysis.

Also, $\lambda_N^2$ is the rescaled current coupling $\lambda_N^2 \equiv \lambda^2/4$.

We only need to carry out four separate calculations for $\Sigma^+(uus)$, $\Sigma^0(uus)$, $\Xi^+(ssd)$ and $\Lambda(uus)$. The QCD
FIG. 2: Non-mass diagrams considered for the octet baryon magnetic moments.

FIG. 3: Diagrams considered for the strange quark mass corrections to the octet baryon magnetic moments.
sum rules for other members can be obtained from them by making appropriate substitutions specified below.

For $\Sigma^+$ at WE:

\[
\begin{align*}
c_1 &= \frac{1}{10} [(1 + \beta)^2 c_s - 2(3 + 2\beta + 3\beta^2)c_v]; \\
c_2 &= \frac{1}{10} (1 + \beta)[(-1 + 3\beta)c_{fs}\phi - 2(1 + 3\beta)c_u]; \\
c_3 &= \frac{1}{3} (1 + \beta)((1 + \beta(c_{fs}\phi - 2c_u(1 - \beta + f_s + \beta f_s))]; \\
c_4 &= \frac{1}{3} (3 - 2\beta + 3\beta^2)c_s + 2(11 + 6\beta + 11\beta^2)c_v]; \\
c_5 &= \frac{1}{3} (3 - 18\beta + 3\beta^2 - 2f_s + 3\beta^2)c_v + (-5 + 2\beta + 27\beta^2 - 9f_s + 6\beta f_s + 27\beta^2 f_s)c_u]; \\
c_6 &= \frac{1}{3} (-1 + \beta)(1 + \beta)c_{fs}\phi(\theta - \xi) + 2c_u(4\kappa + 6\kappa + \xi)); \\
c_7 &= \frac{1}{3} (1 + \beta)c_v(-3 + 3\beta + 2f_s + 2\beta f_s) + 2c_u(-1 + \beta + 8f_s + 8\beta f_s); \\
c_8 &= \frac{1}{3} (-1 + \beta)[(1 + \beta)c_{fs}\phi(\theta - \xi) + c_u(-2\kappa + 2\kappa + 10f_s + 10\beta f_s + 10\beta\kappa + \xi - \beta f_{s}\Phi + f_s\xi + \beta f_{s}\xi)]; \\
c_9 &= -\frac{1}{27}\left((7(1 + \beta)c_{fs}\phi - c_u(3 - 3\beta + f_s + \beta f_s))]; \\
c_{10} &= -\frac{1}{27}((1 - 14\beta + \beta^2)c_s + (-23 - 2\beta + 13\beta^2)c_v(1 + f_s)].
\end{align*}
\]

For $\Xi^0$ at WE:

\[
\begin{align*}
c_1 &= \frac{1}{10} [(1 + \beta)^2 c_s - 2(3 + 2\beta + 3\beta^2)c_v]; \\
c_2 &= \frac{1}{10} (1 + \beta)[(-1 + 3\beta)c_{fs}\phi - 2(1 + 3\beta)c_u]; \\
c_3 &= \frac{1}{3} (1 + \beta)((1 + \beta(c_{fs}\phi - 2c_u(1 - \beta + f_s + \beta f_s))]; \\
c_4 &= \frac{1}{3} (3 - 2\beta + 3\beta^2)c_s + 2(11 + 6\beta + 11\beta^2)c_v]; \\
c_5 &= \frac{1}{3} (3 - 18\beta + 3\beta^2 - 2f_s + 3\beta^2)c_v + (-5 + 2\beta + 27\beta^2 - 9f_s + 6\beta f_s + 27\beta^2 f_s)c_u]; \\
c_6 &= \frac{1}{3} (-1 + \beta)(1 + \beta)c_{fs}\phi(\theta - \xi) + 2c_u(4\kappa + 6\kappa + \xi)); \\
c_7 &= \frac{1}{3} (1 + \beta)c_v(-3 + 3\beta + 2f_s + 2\beta f_s) + 2c_u(-1 + \beta + 8f_s + 8\beta f_s); \\
c_8 &= \frac{1}{3} (-1 + \beta)[(1 + \beta)c_{fs}\phi(\theta - \xi) + c_u(-2\kappa + 2\kappa + 10f_s + 10\beta f_s + 10\beta\kappa + \xi - \beta f_{s}\Phi + f_s\xi + \beta f_{s}\xi)]; \\
c_9 &= -\frac{1}{27}\left((7(1 + \beta)c_{fs}\phi - c_u(3 - 3\beta + f_s + \beta f_s))]; \\
c_{10} &= -\frac{1}{27}((1 - 14\beta + \beta^2)c_s + (-23 - 2\beta + 13\beta^2)c_v(1 + f_s)].
\end{align*}
\]

For $\Lambda$ at WE:

\[
\begin{align*}
c_1 &= \frac{1}{10} ((-1 + \beta)^2 (c_d + c_u) + (13 + 10\beta + 13\beta^2)c_v); \\
c_2 &= \frac{1}{10} (1 + \beta)((-1 + \beta)(c_d + c_u) - (1 + 5\beta)c_{fs}\phi); \\
c_3 &= \frac{1}{10} ((-1 + \beta)(c_d + c_u)(1 - \beta + f_s + 5\beta f_s) - 2(5 + \beta)c_{fs}\phi); \\
c_4 &= \frac{1}{10} ((17 + 2\beta + 17\beta^2)(c_v + c_u) + (41 + 26\beta + 41\beta^2)c_s); \\
c_5 &= \frac{1}{10} (c_s(-78 + \beta(84 - 16f_s) + \beta^2(210 - 4f_s) + 20f_s) + (1 + \beta)(c_d + c_u)(7 + 3f_s + \beta(41 + 33f_s))); \\
c_6 &= \frac{1}{10} ((-1 + \beta)(c_d + c_u)(8(1 + 2\beta)\kappa + (5 + \beta)\xi) + (c_d + c_u)(((20 + 22\beta)\kappa - (1 + 2\beta)\xi)); \\
c_7 &= \frac{1}{10} ((1 + \beta)(c_d(39 + 33\beta - 10f_s - 2\beta f_s) + (c_d + c_u)(1 - \beta + 4f_s + 20\beta f_s)); \\
c_8 &= \frac{1}{10} ((1 + \beta)(2c_{fs}\phi(8(1 + 2\beta)\kappa + (5 + \beta)\xi) + (c_d + c_u)(2(19 + 17\beta + f_s + 5\beta f_s)\kappa - (1 - \beta + f_s + 5\beta f_s)\xi)); \\
c_9 &= \frac{1}{10} ((-1 + \beta)((c_d + c_u)(5 + 3\beta + 3f_s + 7\beta f_s) - 2(5 + \beta)c_{fs}\phi); \\
c_{10} &= \frac{1}{10} ((62 - 4\beta - 34\beta^2)c_s - (-7 - 10\beta + 5\beta^2)(c_d + c_u)(1 + f_s)).
\end{align*}
\]

At the structure WO, the sum rules can be expressed in the following form

\[
\begin{align*}
c_1 m_s L^{-8/9} E_2(w) M^4 + c_2 \chi a L^{-16/27} E_2(w) M^4 + (c_3 + c_4) a E_1(w) M^2 + c_5 m_s \chi a^2 L^{-16/27} E_2(w) + c_6 \chi a b L^{-16/27} E_0(w) + c_7 (c_8 + c_9) m_s a^2 + c_0 a b \leq \mathcal{M} + \mathcal{M} = -\frac{1}{2} \chi N M_N \left[ \frac{2\chi N}{M_N} + \frac{2N - 1}{M_N} + \mathcal{A} \right] e^{-M^2 / M^2}.
\end{align*}
\]
For $\Sigma^+$ at WO:
\[
\begin{align*}
c_1 &= -\frac{1}{2}(-1 + \beta)((1 + \beta)c_s - 2c_u); \\
c_2 &= -\frac{1}{2}(-1 + \beta)[(1 + \beta)c_s f_s \phi + 18(1 + \beta)c_u]; \\
c_3 &= \frac{1}{2}(-1 + \beta)[c_s(-6 - 6\beta - f_s + 3\beta f_s) - 6c_u(2 + 2\beta - f_s + \beta f_s)]; \\
c_4 &= \frac{1}{2}(-1 + \beta)[(1 + \beta)c_s f_s \phi(14\xi - 13\xi) - 18(1 + \beta)c_u(2\xi + \xi)]; \\
c_5 &= -\frac{12}{576}[(3 + 2\beta + 3\beta^2)c_s f_s \phi - (3 + 4\beta + 9\beta^2)c_u(1 + f_s)]; \\
c_6 &= -\frac{1}{576}(-1 + \beta)[(1 + \beta)c_s f_s \phi - 18(1 + \beta)c_u]; \\
c_7 &= -\frac{1}{576}[(c_s(-3 + 3\beta^2 + 5f_s - 2\beta f_s + 5\beta^2 f_s) - c_u(3 + 4\beta + 9\beta^2 - 3f_s + 10\beta f_s + 9\beta^2 f_s)]; \\
c_8 &= -\frac{1}{576}[(c_s f_s \phi(4\xi + 8\beta + 4\beta^2\xi + \xi - 10\xi + 3\xi^2)] \\
&\quad - c_u(-3 + 4\beta + 9\beta^2)(1 + f_s)\xi + 4(2\beta + 6\beta^2 + 3f_s + 2\beta f_s + 3\beta^2 f_s)\xi); \\
c_9 &= -\frac{1}{576}[c_s - c_u(-3 + 3\beta^2 - f_s + 2\beta f_s)].
\end{align*}
\]

For $\Xi^0$ at WO:
\[
\begin{align*}
c_1 &= \frac{1}{2}(-1 + \beta)((1 + \beta)c_u - 2c_s); \\
c_2 &= -\frac{1}{2}(-1 + \beta)[(1 + \beta)c_u + 18(1 + \beta)c_s f_s \phi]; \\
c_3 &= \frac{1}{2}(-1 + \beta)[c_s(-6 - 6\beta - f_s + 3\beta f_s) - 6c_u(2 + 2\beta - f_s + \beta f_s)]; \\
c_4 &= \frac{1}{2}(-1 + \beta)[(1 + \beta)c_s f_s \phi(14\xi - 13\xi) - 18(1 + \beta)c_u(2\xi + \xi)]; \\
c_5 &= -\frac{12}{576}[(3 + 2\beta + 3\beta^2)c_s f_s \phi - (3 + 4\beta + 9\beta^2)c_u(1 + f_s)]; \\
c_6 &= -\frac{1}{576}(-1 + \beta)[(1 + \beta)c_s f_s \phi - 18(1 + \beta)c_u]; \\
c_7 &= -\frac{1}{576}[(c_s(-3 + 3\beta^2 + 5f_s - 2\beta f_s + 5\beta^2 f_s) - c_u(3 + 4\beta + 9\beta^2 - 3f_s + 10\beta f_s + 9\beta^2 f_s)]; \\
c_8 &= -\frac{1}{576}[(c_s f_s \phi(4\xi + 8\beta + 4\beta^2\xi + \xi - 10\xi + 3\xi^2)] \\
&\quad - c_u(-3 + 4\beta + 9\beta^2)(1 + f_s)\xi + 4(2\beta + 6\beta^2 + 3f_s + 2\beta f_s + 3\beta^2 f_s)\xi); \\
c_9 &= -\frac{1}{576}[3c_u - c_s(-3 + 3\beta^2 - f_s + 2\beta f_s)].
\end{align*}
\]

For $\Lambda$ at WO:
\[
\begin{align*}
c_1 &= \frac{1}{2}(-1 + \beta)((cd + c_u)(1 + 2\beta) - (5 + \beta)c_u); \\
c_2 &= -\frac{1}{2}(-1 + \beta)((1 + \beta)\xi + (37 + 35\beta)c_s f_s \phi); \\
c_3 &= -\frac{1}{2}(-1 + \beta)((cd + c_u)(14 + 15\beta(22 - 3f_s + 3f_s) - 1) + \xi + 30 - 6\beta + 35\beta f_s + 37\beta f_s)); \\
c_4 &= \frac{1}{2}(-1 + \beta)(cd + c_u)(2(-3 - 5\beta f_s + 3\beta^2 f_s) + \xi + 30 - 34\beta f_s + 4\beta + 6\beta f_s + 6\beta f_s)); \\
c_5 &= \frac{1}{2}(-1 + \beta)((cd + c_u)(2(-3 - 5\beta f_s + 3\beta^2 f_s) + \xi + 30 + 34\beta f_s + 3\beta^2 f_s + 6\beta f_s)); \\
c_6 &= \frac{1}{12288}((-1 + \beta)(11 + 7\beta)(cd + c_u) + (35 + 37\beta)c_s f_s \phi); \\
c_7 &= \frac{1}{12288}((-1 + \beta)(cd + c_u)(-7 - 7\beta - f_s + 13\beta f_s) + \xi + 30 + 34\beta f_s + 4\beta + 6\beta f_s + 6\beta f_s)); \\
c_8 &= \frac{1}{12288}(2c_s f_s \phi(4\beta + 10\beta^2 + 9\beta^3 f_s + 2\beta(1 + 23 + 35\beta^2 f_s)) \\
&\quad + (-1 + \beta)(cd + c_u)(4(-4 - 23 + 5f_s + 7\beta f_s) - (5 + 11\beta)(1 + f_s))\xi); \\
c_9 &= \frac{1}{12288}((-1 + \beta)(2(5 + 5\beta) + cd + c_u)(5 + 5\beta + 6\beta f_s + 13\beta f_s)).
\end{align*}
\]

At the structure $W_2$, the sum rules can be expressed in the following form
\[
\begin{align*}
c_1 m_s L^{-8/9} E_1(w)M^2 + c_2 c_s a L^{-16/27} E_1(w)M^2 + (c_3 + c_4) a E_0(w) + c_5 m_s a^2 L^{-16/27} E_0(w) + c_6 m_s^2 a L^{-4/9} \frac{1}{M^2} \\
&+ c_7 a b L^{-16/27} \frac{1}{M^2} + (c_8 + c_9) m_s a^2 \frac{1}{M^2} + c_{10} a b \frac{1}{M^2}
= -\frac{\lambda^2}{M^2} \left(2\nu_{N-1} - A_1 \right) e^{-M^2 / M^2}.
\end{align*}
\]

For $\Sigma^+$ at $W_2$:
\[
\begin{align*}
c_1 &= \frac{1}{2}(-1 + \beta)((1 + \beta)c_s - 2c_u); \\
c_2 &= -\frac{1}{2}(-1 + \beta)(1 + \beta)^2 c_s f_s \phi; \\
c_3 &= -\frac{1}{2}(-1 + \beta)[(c_s(2 + 2\beta - f_s + \beta f_s) + 2c_u(-2 - 2\beta - f_s + \beta f_s)]; \\
c_4 &= \frac{1}{2}(-1 + \beta)[c_s f_s \phi + 2(1 + \beta)c_u][2\xi - \xi]; \\
c_5 &= -\frac{1}{2}(-1 + \beta)[c_s f_s \phi + c_u(-1 - \beta - f_s + \beta f_s)]; \\
c_6 &= \frac{1}{2}(-1 + \beta)[7(1 + \beta)c_s + c_u(-1 - \beta - 3f_s + 3\beta f_s)]; \\
c_7 &= \frac{1}{2}(-1 + \beta)[(1 + \beta)^2 c_s f_s \phi]; \\
c_8 &= \frac{1}{2}(-1 + \beta)[(3 + 3\beta^2 + 5f_s - 2\beta f_s + 5\beta^2 f_s) - c_u(3 + 4\beta + 9\beta^2 - 3f_s + 10\beta f_s + 9\beta^2 f_s)]; \\
c_9 &= \frac{1}{2}(-1 + \beta)[c_s f_s \phi(1 - 10\beta + \beta^2 f_s) + (1 + \beta)^2 \xi] \\
&\quad - c_u(2(5 + 6\beta^2 + 3f_s + 2\beta f_s + 3\beta^2 f_s) - (3 + 4\beta + 9\beta^2)(1 + f_s)\xi); \\
c_10 &= \frac{1}{288}(-1 + \beta)((1 + \beta)c_s - c_u(-3 - 3\beta - f_s + \beta f_s)).
\end{align*}
\]
For Ξ⁰ at WO₂:

\[
\begin{align*}
c_1 &= -\frac{1}{2}(1 + \beta)(c_d + c_u)(1 + 2\beta) - (5 + 3\beta)c_s; \\
c_2 &= -\frac{1}{2}(1 + \beta)(c_d + c_u)(2\beta + 6) - f_s) - f_s) + c_s(10 + 3f_s + \beta(2 + 5f_s)); \\
c_3 &= \frac{1}{12}(1 + \beta)(-7 + 3\beta)(c_d + c_u) + (5 + 3\beta)c_s f_s)(2\kappa - \xi); \\
c_4 &= \frac{1}{16}(-1 + \beta)(c_d c_u + (1 - \beta)f_s - 3 + 3\beta); \\
c_5 &= \frac{1}{144}(-1 + \beta)(2c_u + c_s) - f_s) + c_s(1 - \beta)(2 + 5f_s)); \\
c_6 &= \frac{1}{144}(-1 + \beta)(-(5 + 3\beta)c_s + (c_d + c_u)(3 + 4\beta + 3f_s + 3\beta)f_s)); \\
c_7 &= \frac{1}{144}(-1 + \beta)(2(c_d + c_u) - c_s f_s); \\
c_8 &= \frac{1}{144}(-1 + \beta)(-7 + 3\beta)c_s + (c_d + c_u)(1 + 2\beta - f_s) - 13\beta f_s) - 2c_s(15 + 17f_s + 2\beta(6 + 7f_s) + \beta^2(3 + 41f_s)); \\
c_9 &= \frac{1}{144}(2c_u f_s)(-4(7 + 10\beta + 19\beta^2)\kappa + (11 + 26\beta + 35\beta^2)\xi) \\
&\quad - (1 + \beta)(c_d + c_u)(4(-4 - 2\beta + 5f_s + 7\beta f_s)\kappa - (5 + 11\beta)(1 + f_s)\xi); \\
c_{10} &= -\frac{1}{2588}((1 + \beta)(2(5 + \beta)c_s + (c_d + c_u)(5 + \beta + 11f_s + 13\beta f_s)).
\end{align*}
\]

For Λ at WO₂:

\[
\begin{align*}
c_1 &= -\frac{1}{2}(1 + \beta)(c_d + c_u)(1 + 2\beta) - (5 + 3\beta)c_s; \\
c_2 &= -\frac{1}{2}(1 + \beta)(c_d + c_u)(2\beta + 6) - f_s) - f_s) + c_s(10 + 3f_s + \beta(2 + 5f_s)); \\
c_3 &= \frac{1}{12}(1 + \beta)(-7 + 3\beta)(c_d + c_u) + (5 + 3\beta)c_s f_s)(2\kappa - \xi); \\
c_4 &= \frac{1}{16}(-1 + \beta)(c_d c_u + (1 - \beta)f_s - 3 + 3\beta); \\
c_5 &= \frac{1}{144}(-1 + \beta)(2c_u + c_s) - f_s) + c_s(1 - \beta)(2 + 5f_s)); \\
c_6 &= \frac{1}{144}(-1 + \beta)(-(5 + 3\beta)c_s + (c_d + c_u)(3 + 4\beta + 3f_s + 3\beta)f_s)); \\
c_7 &= \frac{1}{144}(-1 + \beta)(2(c_d + c_u) - c_s f_s); \\
c_8 &= \frac{1}{144}(-1 + \beta)(-7 + 3\beta)c_s + (c_d + c_u)(1 + 2\beta - f_s) - 13\beta f_s) - 2c_s(15 + 17f_s + 2\beta(6 + 7f_s) + \beta^2(3 + 41f_s)); \\
c_9 &= \frac{1}{144}(2c_u f_s)(-4(7 + 10\beta + 19\beta^2)\kappa + (11 + 26\beta + 35\beta^2)\xi) \\
&\quad - (1 + \beta)(c_d + c_u)(4(-4 - 2\beta + 5f_s + 7\beta f_s)\kappa - (5 + 11\beta)(1 + f_s)\xi); \\
c_{10} &= -\frac{1}{2588}((1 + \beta)(2(5 + \beta)c_s + (c_d + c_u)(5 + \beta + 11f_s + 13\beta f_s)).
\end{align*}
\]

It is not necessary to list all the coefficients for all 8 members since the coefficients for other members of the octet family can be obtained by appropriate replacements of quark contents in the following way:

- for proton p, replace s quark by d quark in Σ⁺.
- for neutron n, exchange d quark with u quark in proton p,
- for Σ⁻, replace u quark by d quark in Σ⁺,
- for Ξ⁻, replace u quark by d quark in Ξ⁰,
- for Σ⁰, change corresponding factors in Ξ⁰.

Here the conversions between u and d quarks are achieved by simply switching their charge factors e_u and e_d. Moreover, The conversions from s quark to u or d quarks involve setting m_s = 0, f = φ = 1, in addition to the switching of charge factors. This way, they can also provide additional checks for our calculations.

At this point, we can make some comparisons with previous calculations in Ref. [3, 4, 7]. First, we use general interpolating fields where we can vary β to achieve the best match in sum rules. The previous calculations correspond to a fixed value of β=-1. This effect was studied in detail in Ref. [10], and it was found that β = -1.2 is the optimal value. Most of our results are at β = -1.2. Second, we have checked that our sum rules agree with those in the previous calculations for the most part. For example, for the proton at WE₁, we completely agree except for the κ - 2ξ term in Eq. (2.16) in Ref. [3]. In all of our sum rules, we have the combination 2κ - ξ instead of κ - 2ξ. For the strange members (Σ, Ξ, Λ), they have 8 terms in the OPE, while we have 10 terms. For the sum rules at structure WO₂, they have only 3 terms, while we have 9 terms. For the sum rules at structure WO₂, they have only 4 terms, while we have 10 terms. Third, they only analyzed the sum rules at structure WE₁, while we will examine all the structures. Fourth, we use a completely different analysis method.

Before going into the analysis, we would like to point out some relations among the correlation functions (OPE) based on symmetries, which lead to the same relations in the magnetic moments. In exact SU(3)-flavor symmetry, it is known that the magnetic moments of the octet family are related by (see, for example, Ref. [20])

\[
\begin{align*}
\mu_{Σ⁺} &= \mu_p, \\
2\mu_Λ &= \mu_n, \\
\mu_{Σ⁰} &= \mu_Σ, \\
\mu_{Ξ⁰} &= \mu_Ξ.
\end{align*}
\]

These relations are borne out in the OPE of our sum rules if SU(3)-flavor symmetry is enforced. They are only approximately true since SU(3)-flavor symmetry is broken by the strange quark. Here we have the advantage of
studying the symmetry-breaking effects since the terms are explicit in our QCD sum rules.

IV. SUM RULE ANALYSIS

The sum rules for magnetic moments have the generic form of OPE - ESC = Pole + Transition, or

$$\Pi_{\text{mag}}(QCD, \beta, w, M^2) = \tilde{\lambda}_N^2 \left( \frac{\mu_N}{M^2} + A \right) e^{-\Delta_1^2/M^2},$$

(50)

where QCD represents all the QCD input parameters. The task then becomes: given the function $\Pi_{\text{mag}}$ with known QCD input parameters and the ability to vary $\beta$, find the phenomenological parameters (magnetic moment $\mu_N$, transition strength $A$, and continuum threshold $\Delta_1$) by matching the two sides over some region in the Borel mass $M$. A $\chi^2$ minimization is best suited for this purpose. It turns out that there are too many fit parameters for this procedure to be successful in general. To alleviate the situation, we employ the corresponding mass sum rules which have a similar generic form of OPE - ESC = Pole + Transition,

$$\Pi_{\text{mass}}(QCD, \beta, w_1, M^2) = \tilde{\lambda}_N^2 e^{-\Delta_1^2/M^2},$$

(51)

which shares some of the common parameters. Note that the continuum threshold may not be the same in the two sum rules. By taking the ratio of the two equations, we are left with

$$\frac{\Pi_{\text{mag}}(QCD, \beta, w, M^2)}{\Pi_{\text{mass}}(QCD, \beta, w_1, M^2)} = \frac{\mu_N}{M^2} + A.$$  

(52)

This is the form we are going to implement. By plotting the two sides as a function of $1/M^2$, the slope will be the magnetic moment and the intercept the transition strength. The linearity (or deviation from it) of the left-hand side gives an indication of OPE convergence and the role of excited states. The two sides are expected to match for a good sum rule. This way of matching the sum rules has two advantages. First, the slope, which is the magnetic moment of interest, is usually better determined than the intercept. Second, by allowing the possibility of different continuum thresholds, we ensure that both sum rules stay in their valid regimes.

We use the chiral-even mass sum rules in Ref. [21] which are listed here in the same notation,

$$p_1 L^{-4/9} \Pi_3(w_1) M^6 + p_2 L^{-4/9} \Pi_1(w_1) M^2 + p_3 m_s A L^{-11/9} + p_4 a^2 L^{-11/9} + p_5 a^2 k_c L^{-11/9} + p_6 m_0^2 a^2 L^{-2/27} \frac{1}{M^2} = \tilde{\lambda}_N^2 e^{-\Delta_1^2/M^2}.$$  

(53)

The coefficients for $N$ are:

$$p_1 = \frac{1}{60}(5 + \beta + 5\beta^2);$$
$$p_2 = \frac{1}{250}(5 + \beta + 5\beta^2);$$
$$p_3 = 0;$$
$$p_4 = \frac{1}{27}(7 - 2\beta - 5\beta);$$
$$p_5 = 0;$$
$$p_6 = -\frac{1}{80}(13 - 2\beta - 11\beta^2).$$

(54)

For $\Lambda$:

$$p_1 = \frac{1}{60}(5 + 2\beta + 5\beta^2);$$
$$p_2 = \frac{1}{250}(5 + 2\beta + 5\beta^2);$$
$$p_3 = \frac{1}{500}((20 - 15 f_s) - (16 + 6 f_s) \beta - (4 + 15 f_s) \beta^2);$$
$$p_4 = \frac{1}{100}((4 f_s - 5 - 6\beta) + (4 f_s - 5 + 6\beta) \beta);$$
$$p_5 = \frac{1}{200}((10 f_s + 11) + (2 - 8 f_s) \beta - (2 f_s + 13)\beta^2);$$
$$p_6 = \frac{1}{200}((16 f_s - 23) + (8 f_s - 2) \beta + (8 f_s + 25)\beta^2).$$

(55)

For $\Sigma$:

$$p_1 = \frac{1}{60}(5 + 2\beta + 5\beta^2);$$
$$p_2 = \frac{1}{250}(5 + 2\beta + 5\beta^2);$$
$$p_3 = \frac{1}{100}((12 - 5 f_s) - 2 f_s \beta - (12 + 5 f_s) \beta^2);$$
$$p_4 = -\frac{1}{90}((4 f_s + 21 + 18\beta) + 4 f_s \beta + (4 f_s - 21 - 18\beta)\beta^2);$$
$$p_5 = \frac{1}{90}((6 f_s + 1) - 2\beta - (6 f_s - 1)\beta^2);$$
$$p_6 = \frac{1}{90}((12 f_s + 1) - 2\beta - (12 f_s - 1)\beta^2).$$

(56)

For $\Xi$:

$$p_1 = \frac{1}{60}(5 + 2\beta + 5\beta^2);$$
$$p_2 = \frac{1}{250}(5 + 2\beta + 5\beta^2);$$
$$p_3 = \frac{1}{60}((2 - f_s) - 2 f_s \beta - (2 + f_s)\beta^2);$$
$$p_4 = -\frac{1}{90}((15 - f_s + 18\beta) - 10 f_s \beta - (15 + f_s + 18\beta)\beta^2);$$
$$p_5 = \frac{1}{90}((f_s + 6) - 2 f_s \beta - (f_s - 6)\beta^2);$$
$$p_6 = -\frac{1}{90}((f_s + 12) - 2 f_s \beta - (f_s - 12)\beta^2).$$

(57)

The function $t$ is defined as $t \equiv \ln \frac{M^2}{m^2} - \gamma_{EM}$ with $\gamma_{EM} \approx 0.577$ the Euler-Mascheroni constant. Use this mass sum rule for the coupling constant for magnetic moment sum rules, and move to the left side, then only the magnetic moment $\mu_N$ and the transition strength $A$ dependence are on the right hand side.

We use the Monte-Carlo procedure first introduced in Ref. [19] to carry out the search which allows a rigorous error analysis. In this method, the entire phase-space of the input QCD parameters is explored simultaneously, and is mapped into uncertainties in the phenomenological parameters. This lead to more realistic uncertainty estimates than traditional approaches.

First, a set of randomly-selected, Gaussianly-distributed condensates are generated with a assigned uncertainties. Here we give 10% for the uncertainties of input parameters, and this number can be adjusted to test the sensitivity of the QCD parameters. Then the OPE is constructed in the Borel window with evenly distributed points $M_j$. Note that the uncertainties in the OPE are not uniform throughout the Borel window. They are larger at the lower end where uncertainties in the higher-dimensional condensates dominate. Thus, it is crucial that the appropriate weight is used in the calculation of $\chi^2$. For the OPE obtained from the $k$th set of QCD parameters, the $\chi^2$ per degree of freedom is

$$\frac{\chi^2}{N_{DF}} = \sum_{k=1}^{n_B} \frac{\Pi_{OP-E}(M^2_j, \beta, w, w_1) - \Pi_{OP-E}(M^2_j, \mu, A)^2}{(n_B - n_p) \sigma_{OP-E}(M^2_j)^2},$$

(58)

where $\Pi_{OP-E}$ refers to the LHS of Eq. (52) and $\Pi_{OP-E}$ its RHS. The integer $n_p$ is the number of phenomenologi-
v. result and discussion

We have 24 sum rules in total to analyze: 3 for each member of the octet. For each sum rule, we have in principle 5 parameters to determine: \( \mu, A, w, w_1, \beta \). But a search treating all five parameters as free does not work because there is not enough information in the OPE. In fact, the freedom to vary \( \beta \) can be used as an advantage to yield the optimal match. We find that \( \beta = -1.2 \) gives the best match in most cases. This agrees with the value suggested in Ref. [19]. One exception is the proton: we found a better solution at \( \beta = -0.4 \) than at \( \beta = -1.2 \). Another parameter that can be used to our advantage is the continuum threshold \( w_1 \) for the corresponding mass sum rule. We fix it to the value that gives the best solution to the mass sum rule independently. The following values for \( w_1 \) are used: for the nucleon, \( w_1 = 1.44 \text{ GeV} \); for \( \Lambda, w_1 = 1.60 \text{ GeV} \); for \( \Sigma, w_1 = 1.66 \text{ GeV} \); for \( \Xi, w_1 = 1.82 \text{ GeV} \). In this way the magnetic moment sum rule and the mass sum rule can stay in their respective valid Borel regimes. This leaves us with three parameters: \( \mu, A, w \). Unfortunately, a three-parameter search is either unstable or returns values for \( w \) smaller than the particle mass, an unphysical situation. Again we think this is a symptom of insufficient information in the OPE. So we are forced to fix the continuum threshold \( w \) that corresponds to the best match for the central values of the QCD parameters.

A. the sum rule at \( \text{WE}_1 \)

The results determined this way at the \( \text{WE}_1 \) structure are displayed in Table I. The Borel window is determined by the following two criteria: OPE convergence which gives the lower bound, and ground-state dominance which gives the upper bound. It is done iteratively. For each value of \( \beta \), we adjust the Borel window until the best solution is found. We see that our calculated magnetic moments agree with experiment fairly well within error bars.

We stress that the errors are derived from Monte-Carlo distributions which give the most realistic estimation of the uncertainties. An example of such distributions is given in Fig. 4. We see that they are roughly Gaussian distributions. The central value is taken as the average, and the error is one standard deviation of the distribution. We found about 10% accuracy for the magnetic moments in our Monte-Carlo analysis, resulting from 10% uniform uncertainty in all the QCD input parameters. Of course, the uncertainties in the QCD parameters can be non-uniform. For example, we tried the uncertainty assignments (which are quite conservative) in Ref. [19].
and found about 30% uncertainties in our output.

To gain a better appreciation on how the QCD sum rules produce the results, we show Fig. 5 using the proton as an example. There are three graphs in this figure to give three different aspects of the analysis. The first graph shows how the two sides of Eq. (52) match over the Borel window, which should be linear as a function of $1/M^2$, as expected from the right-hand side of this equation. Indeed, we observe excellent linear behavior from the top graph. The middle graphs shows that the leading contribution is the dominant one, which is expected because its sum rule. The bottom graph reveals a surprising result: the excited-state dominates over the pole and the transition. As a result, this sum rule is less reliable. This is the reason why the results extracted from this sum rule. The magnetic moments have larger errors than those from WE$_1$: about 15% as opposed to 10%. The agreement with experiment is reasonable (with the exception of $\Sigma^-$), but not as good as those from WE$_1$. We had to search a wider region in $\beta$ to find the best match. The transition contribution ($A$) are larger for the strange particles, as well as their errors.

Fig. 6 shows the details of the analysis in the case of the proton. The matching is very good, as indicated in the top graph. The middle graphs shows that the leading contribution in the OPE ($M^4$ term) is $\chi a$, followed by the quark condensate $a (M^2)$ term. The condensate $\chi ab (M^0$ term) and $ab (M^-2$ term) are very small in this sum rule. The bottom graph reveals a surprising result: the excited-state dominates over the pole and the transition. As a result, this sum rule is less reliable. This is the reason why the results from this sum rule are not as good as those from WE$_1$. This sum rule also shows the importance of checking the individual terms in the phenomenological side, in addition to looking at the best match of the two sides. In this case, there is no pole dominance, even though the leading terms is non-perturbative and the match is almost perfect.

### B. The Sum Rule at WO$_2$

Next, we analyze the sum rule in Eq. (45) at the structure WO$_1$, using the same procedure. Table II displays the results extracted from this sum rule. The magnetic moments have larger errors than those from WE$_1$: about 15% as opposed to 10%. The agreement with experiment is reasonable (with the exception of $\Sigma^-$), but not as good as those from WE$_1$. We had to search a wider region in $\beta$ to find the best match. The transition contribution ($A$) are larger for the strange particles, as well as their errors.

### C. The Sum Rule at WO$_2$

Finally, we present the results from the sum rule in Eq. (45) at the structure WO$_2$ in Table III. The agreement with experiment is not as good as the other two sum rules. For example, $\Sigma^-$ and $\Xi^-$ have the wrong sign. Fig. 7 shows the details of the analysis for the proton. The matching is very good, as indicated in the top graph. The middle graph shows that the leading contri-
bution in the OPE is $M^2$ with a coefficient of $\chi a$, followed by the $M^0$ term. The $1/M^2$ term is slightly negative, while the $1/M^4$ term is very small. The bottom graph shows that the excited-state dominates over the pole and the transition, like the sum rule from WO$_1$, but the relative size of the pole is much larger. Since the WO$_2$ sum rule has power corrections up to $1/M^4$, it is expected to be more reliable than the WO$_1$ sum rule. But our analysis shows that this advantage is offset by the smallness of the $1/M^2$ and $1/M^4$ terms. As a result, the reliability of the WO$_2$ sum rule is about the same as the WO$_1$ sum rule.

We have performed the same analysis for all the members and all three structures. Fig. 5 shows the graphs for this. In this case, the slope is negative. Again, the sum rule at WE$_1$ has excellent convergence properties. The WO$_1$ sum rule has a good match, but the pole is less than the excited-state. The WO$_2$ sum rule does not have a good match. Fig. 6 shows the case for the $\Sigma^0$, which has all three quark contributions (u, d and s).

Overall, based on the quality of the match, the broadness of the Borel window and its reach into the lower end, the size of the continuum contribution, and the OPE convergence, we find that the sum rule at WE$_1$ is the most reliable of the three sum rules.

### D. Some physics discussions

Based on the results of our comprehensive analysis, we conclude that the QCD sum rules at WE$_1$ in Eq. (5) are the most reliable. Here we discuss some physics implications of the results extracted from them (Table I). First we look at some ratios of magnetic moments listed Table IV. Here we compare our results with those from the SU(6) symmetry, lattice calculations $^{22}$ and experiment. From the table, we see that the QCD sum rule results compare well against other approaches and experiment. They agree a little better with experiment than the lattice results. Furthermore, our QCD sum rule results are an improvement over the ratios from previous QCD sum rule calculations in Ref. [5].

Next, we consider a few sum rules among magnetic moments that have been discussed in literature. They reveal interesting quark dynamics in the baryons. They are mostly based on SU(6)-symmetry considerations in the quark model. We begin with the sum rule $^{22}$

$$\frac{3(p - \Sigma^+)}{\Xi^- - \Xi^0} = \frac{(p + 3\Lambda)}{p}. \quad (59)$$

It assumed ‘baryon independence’ of quark moments: the independence of which baryon the same quark is in, a concept first mentioned by Franklin $^{24}$. In other words, each quark is not sensitive to the environment it resides in and quarks in different spin states had the same effective moments. In this sum rule, it also assumed that the s quark moment in the $\Lambda$ is the same as in the $\Sigma$ and $\Xi$, even though the spin states are different. This sum rule is violated the most (by a factor of 5) using present values of magnetic moments. This large violation is mostly due to the small difference in the denominator $\Xi^- - \Xi^0$ which magnifies the apparent discrepancy. So this is not a good way of testing baryon independence. Our determination of the ratio of the left hand side over the right hand side (LHS/RHS) is 7.4(1.0), compared to the experimental value of 5.7(4) and the lattice calculation of 4.1(1.5). The error are added in quadrature in forming these ratios.

One interesting sum rule $^{29}$ which is fairly accurately satisfied is

$$p + n = 3\Lambda + \frac{1}{2}(\Sigma^+ + \Sigma^-) - (\Xi^0 + \Xi^-). \quad (60)$$

It is derived using SU(3)-flavor symmetry to characterize the $\Lambda$ wave function. Our determination of the LHS/RHS ratio is 1.24(79), compared to the experimental values of 1.22(5) and the lattice calculation of 1.45(27).

Another sum rule, first derived by Franklin $^{24}$,

$$p - n = \Sigma^+ - \Sigma^- + \Xi^- - \Xi^0, \quad (61)$$

is another test of baryon independence of the quark moments. The strange quarks approximately cancel, leaving only u and d quarks. We give the ratio of 1.20(0.68),

---

**TABLE II: Similar to Table I but for the QCD sum rule in Eq. (41) (structure WO$_1$).**

| \(\beta\) | Region (GeV) | \(w\) (GeV) | \(A\) (GeV$^{-1}$) | \(\mu_n\) (\(\mu_N\)) | Exp. (\(\mu_N\)) |
|---|---|---|---|---|---|
| \(p\) | -0.8 | 1.4 to 1.6 | 1.50 | 1.03±0.16 | 2.67±0.16 | 2.79 |
| \(n\) | -1.2 | 1.2 to 1.4 | 1.40 | -0.54±0.11 | -1.70±0.11 | -1.91 |
| \(\Sigma^+\) | -0.6 | 1.5 to 1.7 | 1.60 | -2.3±0.31 | -0.62±0.17 | -0.61 |
| \(\Sigma^0\) | -1.0 | 1.4 to 1.6 | 1.70 | 0.23±0.11 | 0.58±0.09 | 0.65 |
| \(\Sigma^-\) | -0.6 | 1.2 to 1.5 | 1.60 | -2.04±0.34 | -0.57±0.26 | -1.16 |
| \(\Xi^0\) | -1.2 | 1.2 to 1.4 | 2.10 | -1.52±0.21 | -1.27±0.15 | -1.25 |
| \(\Xi^-\) | -0.2 | 1.7 to 1.8 | 1.90 | -0.4±0.41 | -0.49±0.29 | -0.65 |
while the experiment measurements gives 1.133(10) and lattice results is 1.07(8) for this ratio.

Finally, the Sachs sum rule \[3(p+n) = \Sigma^+ - \Sigma^- - \Xi^- + \Xi^0 \] (62)
is satisfied by the more general extension of SU(6) symmetry and is another test of baryon independence of quark moments. This sum rule is just the sum of the two separate sum rules proposed earlier by Franklin [25]. Our result gives the ratio of 0.86(35) which is in agreement with the experiment measurements of 0.881(11). Whereas it yields an opposite violation with a ratio of 1.29(20) from lattice moments. This contradiction is possibly because the Sachs sum rule may be sensitive to dynamics not included in the lattice calculation.

### E. Individual quark contributions

To gain a deeper understanding of the dynamics, it is useful to consider the individual quark sector contributions to the magnetic moment. In our approach, we can easily dial individual quark contributions to the QCD sum rules. For example, to turn off all u-quark contributions, we set the charge factor \(e_u = 0\). To turn off all s-quark contributions, we set \(e_s = 0, m_s = 0, f = 1\), and \(\phi = 1\). We can extract a number corresponding to each quark contribution from the slope of Eq. (62) as a function of \(1/M^2\). We call this the raw individual quark contributions to the magnetic moments.

Table IV gives the result of raw individual u, d and s quark sector contributions to the magnetic moments from the QCD sum rules at \(\Lambda_{\overline{\text{MS}}} = 1\). It is compared with the lattice QCD result in [22]. The lattice results were rescaled later in [27] and we use the rescaled results for the comparison. Our results agree with the lattice results reasonably well. The biggest discrepancy is that our light quark moments in \(\Sigma^0\) and \(\Xi^-\) are small. In \(\Sigma^0\) and \(\Lambda\) the total of u and d quark moments agree very well with lattice data for light quark moments. Note that only a combined number for light quark \((\mu = \mu_u + \mu_d)\) was given on the lattice [22]. To compare with our separated u and d quark numbers, we break up the lattice number by using the relation \(\mu_u = -2\mu_d\).

In the simple quark model [28], the magnetic moment of the proton is given by \(p = \frac{1}{2}\mu_u - \frac{1}{2}\mu_d\). In the SU(2) limit, there is the relation \(\mu_u = -2\mu_d\). Our results for \(\Sigma^0\) and \(\Lambda\), the two \(uds\) structure baryons, agree with this very well. This relation also suggests that the ratio of the u quark and d quark contributions in proton is \(\frac{1}{2}\mu_u/(\frac{1}{2}\mu_d) = 8\). Our QCD sum rule ratio is 10.6 for \(\beta = -1.2\), which agrees with the lattice ratio of 10.3(7) at \(\kappa_1\). For neutron the quark model ratio is \(\frac{1}{2}\mu_u/(\frac{1}{2}\mu_d) = 2\), and our result is 3.64(40) for this ratio, which differs from the SU(6) spin-flavor symmetry prediction. The lattice ratio is 2.6. The bigger ratio represents an enhancement of the doubly represented quark contribution. These results suggest that although the total magnetic moments ratios agree with SU(6) ratios (see Table IV), the underlying quark dynamics are really quite different from different individual quark contributions.

To include the possible nonstatic effect, Franklin [29] proposed a generalization of SU(6) results so that non-

### Table III: Similar to Table I but for the QCD sum rule in Eq. (45) (structure WO).

| \(\beta\) | Region | \(w\) (GeV) | \(A\) (GeV\(^{-2}\)) | \(\mu_B\) (\(\mu_N\)) | Exp. (\(\mu_N\)) |
|----------|-------|-------------|-----------------|-----------------|-----------------|
| \(p\)    | -1.2  | 1.3 to 1.4  | 1.60            | 0.42 ± 0.07     | 2.53 ± 0.13     | 2.79            |
| \(n\)    | -1.2  | 1.7 to 1.9  | 1.60            | 0.26 ± 0.03     | -1.73 ± 0.28    | -1.91           |
| \(\Lambda\) | -1.2  | 1.3 to 1.4  | 1.90            | -0.85 ± 0.22    | -0.53 ± 0.17    | -0.61           |
| \(\Sigma^+\) | -1.0  | 1.2 to 1.4  | 1.70            | 0.21 ± 0.05     | 1.50 ± 0.11     | 2.45            |
| \(\Sigma^0\) | -1.2  | 1.0 to 1.6  | 1.60            | -0.02 ± 0.02    | 1.04 ± 0.07     | 0.65            |
| \(\Sigma^-\) | -1.2  | 1.4 to 1.6  | 1.65            | 0.0 ± 0.01      | 0.61 ± 0.06     | -1.16           |
| \(\Xi^0\) | -1.2  | 1.6 to 2.0  | 2.1             | -0.08 ± 0.03    | -1.20 ± 0.23    | -1.25           |
| \(\Xi^-\) | -1.2  | 1.4 to 1.5  | 2.2             | 0.22 ± 0.09     | 0.80 ± 0.21     | -0.65           |

### Table IV: A comparison of selected ratios of magnetic moments.

| Ratio | Sum Rule | SU(6) symmetry | Lattice results | Exp. |
|-------|----------|----------------|-----------------|------|
| \(n/p\) | -0.70(9) | -2/3           | -0.63(5)        | -0.68|
| \(\Sigma^-/\Sigma^+\) | -0.50(7) | -1/3           | -0.37(3)        | -0.47|
| \(\Xi^-/\Xi^0\) | 0.56(6)  | 1/2            | 0.58(5)         | 0.52 |
| \(\Xi^0/\Lambda\) | 2.05(56) | 2              | 2.4(5)          | 2.04 |
| \(\Xi^-/\Lambda\) | 1.14(32) | 1              | 1.0(2)          | 1.13 |
It is expected because of the quark mass effects, which is analogous to those seen in the electric properties.

Another way of looking at the individual effective quark moments is by expressing them in terms of baryon magnetic moments using Eq. (63) and isospin symmetry. For example, the d-quark effective moment can be expressed as

$$
\mu_d = -\frac{1}{4}(2p + n) = \frac{1}{4}(\Sigma^- - \Sigma^+).
$$

(67)

Our result indicates $\mu_d = -0.92(14) < -0.86(7)$ using the baryon moments in Table V or in Table I. It agrees well with the experimental moments $\mu_d = -0.918 < -0.894(7)$ and the lattice result of $\mu_d = -1.00(5) < -0.86(6)$.

Similarly the $d'$ quark effective moment is

$$
\mu_{d'} = p + 2n = \Xi^0 - \Xi^-.
$$

(68)

We have $\mu_{d'} = -1.12(39) < -0.51(8)$. It also agrees very well with the experimental moments $\mu_{d'} = -1.003 < -0.578(26)$ although the two sides of this sum don’t agree well.

The strange quark can be isolated as

$$
\mu_s = \frac{1}{4}(\Xi^0 + 2\Xi^-),
\mu_{s'} = -\Sigma^+ - 2\Sigma^-,
\mu_{s''} = \Lambda - \delta.
$$

(69)

Our results are compared with experiment and lattice calculation in Table VI. Not only the results agree with the experiment and lattice calculation, they also roughly agree with the strange quark moments from individual quark moments.

Now, we can look at the quark moment difference such as $\mu_s - \mu_d'$ and $\mu_s - \mu_d$. According to simple quark model, the difference should be the same and approximately as 0.36. In fact, from

$$
\mu_s - \mu_d = 3(p - \Sigma^+),
$$

(70)
QCD sum rules give 1.53(8) and 0.61(12). The experiment gives 1.12(7) and 0.495(11), while lattice calculation gives 1.3(5) and 0.32(17) respectively. The large result of $\mu_s' - \mu_d'$ is difficult to reconcile with any simple model. And Eq. (70) is a poor way to measure the difference of $s$ and $d$ quark contribution.

**F. Correlations**

Our Monte-Carlo analysis affords the opportunity to study the correlations between any two parameters since the entire QCD input phase space is mapped into the...
FIG. 7: Similar to Fig. 5 but at structure WO$_2$ and $\beta = -1.2$.

phenomenological output space. This correlation can be explored by a scatter plot of the two parameters of interest.

Fig. 10 shows the scatter plots for the proton magnetic moment at structure WE$_1$. We see that the magnetic moment has a strong correlation with the vacuum susceptibility $\chi$. It is a negative correlation meaning larger $\chi$ (in absolute terms since $\chi$ is negative) leads to smaller $\mu_B$. A slight negative correlation with the mixed condensate and a slight positive correlation with another vacuum susceptibility $\kappa$ are also observed. Precise determination of the QCD parameters, especially for those that have strong correlations to the output parameters, is crucial for keeping the uncertainties in the spectral parameters under control.

Fig. 11 shows a similar plot for the $\Sigma^0$ at structure WE$_1$. Here we focus on the three vacuum susceptibilities and the three parameters that define the strange quark ($m_s$, $f$ and $\phi$). The correlations with the other condensates are similar to the proton and are not shown. A negative correlation with $\chi$ exists, but not as strong as that for the proton. A slight positive correlation with $m_s$ and $f$ is also observed.

VI. CONCLUSION

We have carried out a comprehensive study of the magnetic moment of octet baryons using the method of QCD sum rules. We derived a new, complete set of QCD sum rules using generalized interpolating fields and examined them by a Monte-Carlo analysis. Here is a summary of our findings.

We proposed a new way of determining the magnetic moments from the slope of straight lines. We find this method more robust than from the normalization (intercept) or from looking for ‘flatness’ as a function of Borel mass. The linearity displayed from the OPE side matches almost perfectly with the phenomenological side in most cases. The method also demonstrates clearly that the transition terms caused by the external field in the intermediate terms cannot be ignored. They are needed to make the two sides of a QCD sum rule match.

Out of the three independent structures, we find that the sum rules from the WE$_1$ structure are the most reliable based on OPE convergence and ground-state pole dominance. The QCD sum rules from this structure are in Eq. (32); its prediction are found in Table I, and convergence properties are displayed in Fig. 5. They should be considered as the best results in this work. The extracted magnetic moments are in good agreement with experiment. These results are used to shed light on a variety of magnetic moment sum rules based on SU(6) spin-flavor symmetries in the quark model, along with experiment and lattice QCD. Reasonable results from the other two structures (WO$_1$ and WO$_2$) are obtained for the first time, but they are less reliable due to poor convergence properties.

Our Monte-Carlo analysis revealed that there is an uncertainty on the level of 10% in the magnetic moments if we assign 10% uncertainty in the QCD input parameters. It goes up to about 30% if we adopt the conservative assignments that have a wide range of uncertainties in Ref. [19]. The Monte-Carlo analysis also revealed some correlations between the input and output parameters. The most sensitive is the vacuum susceptibility $\chi$. So a better determination of this parameter can help improve the accuracy on the magnetic moments and other quantities computed from the same method.

We also isolated the individual quark contributions to the magnetic moments. These contributions provide insight into the rich dynamics in the baryons. By comparing them with the simple quark model and lattice QCD results, we reveal the effects of SU(3)-flavor symmetry breakings in the strange quark, the environment sensi-
tivity of quarks in different baryons.

Taken together, this work can be considered an updated and improved determination of the magnetic moments of octet baryons, bringing it to the same level of sophistication as the decuplet baryons [9]. One possible extension along this line is a calculation of the $\Delta$ electromagnetic transition amplitudes which to our knowledge have not been studied in this method.
