Abstract The Reissner–Nordström black hole – moving mirror correspondence is solved. The beta coefficients reveal that charge makes a black hole radiate fewer particles (neutral massless scalars) per frequency. An old Reissner–Nordström black hole emits particles in an explicit Planck distribution and the temperature range, which is the spectrum of the collapsing star [5] up to gray body factors and different dimensionality (for a recent review see [6]). This paper is organized as follows: Sect. 2 contains the RN metric and matching condition for collapse. Section 3 reveals the moving mirror, and computes the dynamics resulting in asymptotic infinite acceleration. Section 4 demonstrates the all-time spectrum and compares with the Schwarzschild and extremal Reissner–Nordström spectra. In Sect. 5, we conclude. Appendix A has an elementary model with reduced particle creation. Units are $G = h = c = 1$.

1 Introduction

Does the Reissner–Nordström (RN) black hole radiate fewer neutral massless particles than the Schwarzschild black hole? It is well-known that charged black holes are colder and smaller than their neutral cousins (of the same $M$). Consider the range of sizes of the outer horizon of a RN black hole and the temperature range,

$$\frac{1}{2} < \frac{r_s}{r_+} < 1, \quad 0 < \frac{T_+}{T_s} < 1,$$

where the $s$-subscript refers to Schwarzschild, $r_s \equiv 2M$ and $T_s = (4\pi r_s)^{-1}$. The inner and outer horizons of the RN black holes are

$$r_\pm = \frac{1}{2} \left(r_s \pm \sqrt{r_s^2 - 4r_q^2}\right),$$

which are dependent on the two parameters ($M$, $Q$), where $r_q^2 \equiv Q^2$, and the temperature of the outer horizon is [1]

$$T_+ = \frac{\kappa_+}{2\pi} = \frac{2r_+ - r_s}{4\pi r_+^2} = T_s \left(\frac{T_+}{T_s} - 1\right)^2,$$

where $\tilde{T}_+ := \left(4\pi r_+\right)^{-1} > T_s$. In this note, we consider whether the number of neutral massless particles radiated is reduced too. By modeling the RN black hole by a moving mirror [2–4], we solve for the beta coefficients for all times,
We will now coincide the inner and outer regions of the incipient charged black hole (see e.g. Wilczek [8]). The matching condition, as is similar to the textbook case of the Schwarzschild matching in [7], between the flat interior geometry, described by the interior coordinates, \( U = T - r \), and \( V = T + r \), is the trajectory of the nascent black hole origin. The position of the origin is dynamic from the point of view of the outside coordinates. The equation of motion of the center of the black hole is succinctly expressed in terms of the exterior function, \( u(U) \), dependent on interior coordinate, \( U \):

\[
u(U) = U - \frac{\ln \left\{ \frac{2r_+ + U - v_0}{2r_+} \right\}}{\kappa_+} - \frac{\ln \left\{ \frac{2r_+ + U - v_0}{2r_-} \right\}}{\kappa_-}.
\]

This matching, \( r^\text{a}(r = (v_0 - U)/2) = (v_0 - u)/2 \), happens along the light-like shell, \( v_0 \), which is a single advanced time null-ray. Here \( v_0 - v_H \equiv 2r_+ \) because \( u \to +\infty \) at \( U = v_H \). We set the horizon to zero, \( v_H = 0 \), and obtain the trajectory of the origin:

\[
u(U) = U - \frac{1}{\kappa_+} \ln \left\{ \frac{U}{2r_+} \right\} - \frac{1}{\kappa_-} \ln \left\{ \frac{r_+ - 1 - U}{2r_-} \right\}.
\]

Having obtained the origin trajectory \( u(U) \), in terms of light-cone retarded coordinates, we are now in a position to consider its physical effect on the quantum field. The quantized scalar field is not only described by its wave equation of motion but crucially, it must also vanish at \( r = 0 \). This is called the regularity condition of the field. Regularity at the \( r = 0 \) location forces the form of the field modes to behave like a moving mirror (no field behind \( r < 0 \); reflecting off \( r = 0 \)). It reveals the form of field modes, such that \( U \leftrightarrow v \) identification can be made for the Doppler-shifted right movers [7] in an analog flat spacetime system. The mirror trajectory, \( f(v) \leftrightarrow u(U) \) is then a known function of advanced time, which we examine in the next section.

3 Trajectory and dynamics

Now we will state the mirror trajectory and analyze its dynamics, preparing for a computation of the particle production in Sect. 4. The light-cone coordinate mirror trajectory \( f(v) \) in flat spacetime is the light-cone coordinate black hole origin trajectory \( u(U) \) in curved spacetime. Let us study the massless scalar quantum field in \((1 + 1)\)-dimensional Minkowski spacetime in similar spirit to prior studies, e.g. [9]. The corresponding RN moving mirror trajectory from Eq. (10) is

\[
f(v) = v - \frac{9}{4} \ln \left( \frac{v^2}{9} \right) + \frac{1}{4} \ln(v - 2)^2.
\]

Keep in mind the horizon has been set to \( v_H = 0 \), and so \( v \) spans \(-\infty < v < v_H \). The trajectory in spacetime coordinates is plotted in a spacetime plot Fig. 1. A conformal diagram of the accelerated boundary is given in Fig. 2. For an even more simplified vacuum solution model that gives the same result as the RN metric, see Appendix A.

The rapidity, \( \eta = \frac{1}{2} \ln f'(v) \); and proper acceleration, \( \alpha = e^{\eta} f'(v) \); are monotonic functions that diverge in the limit that advanced time approaches the horizon time, \( v \to v_H = 0 \). The limit in the far past, \( v \to -\infty \) is \( (\eta, \alpha) \to 0 \); the mirror is past asymptotically static. The mirror rapidly travels left, off to the speed of light. In the limit that charge goes to zero, \( Q \to 0 \), the function, \( u(U) \leftrightarrow f(v) \), of Eq. (10), recovers the Schwarzshild mirror [10–13], as one expects:

\[
f(v) = v - 4M \ln \left( \frac{v_H - v}{4M} \right).
\]
The trajectory Eq. (11) in a Penrose conformal diagram. The horizon has been set to $v_H = 0$. For illustrative emphasis on the asymptotic behavior, the ratio $Q/M = 86\%$ is fixed, but the mass is changing, $M = 2, 1, 2^{-1}, 4^{-1}, 8^{-1}$; for cyan, black, purple, brown, pink, respectively. The mass dramatically affects the conformal trajectory, demonstrating the horizon approach is more rapid at late times for higher value of the mass.

We will utilize the Schwarzschild surface gravity, $\kappa \equiv (4M)^{-1}$ in the following.

4 Spectrum and particles

The beta Bogoliubov coefficient can be found via [14],

$$\beta_{\omega \omega'} = -n_0 \int_{-\infty}^{v_H} dv \, e^{-i\omega' v - i\omega f'(v)} (\omega f'(v) - \omega'),$$

by setting the horizon $v_H = 0$ for convenience and definiteness, (horizon position will not affect the spectrum because of complex conjugation). The normalization factor is $n_0^{-1} = 4\pi \sqrt{\omega \omega'}$. We will use the RN and Schwarzschild surface gravities as $(\kappa_+ \kappa)$ and also, $\kappa^{-1} = 2(r_+ - r_-)$. An integration by parts simplifies Eq. (14) by ignoring the non-contributing surface terms. To obtain the spectrum, we complex conjugate,

$$N_{\omega \omega'} \equiv |\beta^{\text{RN}}_{\omega \omega'}|^2,$$

which is the particle count per mode-mode squared,

$$|\beta^{\text{RN}}_{\omega \omega'}|^2 = \frac{1}{2\pi \kappa_+ \omega_p} \frac{1}{\omega_p e^{2\pi \omega f/k_+} - 1} e^{-\pi \omega f/k} |U|^2,$$

where $\omega_p \equiv \omega + \omega'$ and the confluent hypergeometric Kummer function of second kind is,

$$U \equiv U \left(\frac{i\omega}{\kappa}, \frac{i\omega}{\kappa}, \frac{i\omega}{\bar{\kappa}}\right).$$

Here $\kappa^{-1} = 4M$, and $\bar{\kappa}^{-1} = 2(r_+ - r_-) = 4\sqrt{M^2 - Q^2}$. The spectrum, which is the main result of this paper, is then,

$$N_{\omega} = \int_{0}^{\infty} N_{\omega \omega'} d\omega',$$

which is plotted in Fig. 3.

Spectrum in Schwarzschild limit

The spectrum for the beta coefficient squared for the RN mirror in the limit that the charge, $Q \to 0$, is the limit where the inner radius goes to zero, $r_- \to 0$. The result is confirmed to be

$$\lim_{r_- \to 0} |\beta^{\text{RN}}_{\omega \omega'}|^2 = |\beta^{\text{S}}_{\omega \omega'}|^2 = \frac{r_+ \omega'}{\pi (e^{4\pi \omega f} - 1)(\omega' + \omega)^2}. $$

In the high frequency regime, where the modes are extremely red-shifted, $\omega' \gg \omega$, one has $N_{\omega \omega'} \equiv |\beta^{\text{S}}_{\omega \omega'}|^2$,

$$N_{\omega \omega'} = \frac{1}{2\pi \kappa \omega'} e^{\omega'/\kappa_+} - 1.$$ 

This confirms that the particle spectrum of Eq. (16), gives the known answer [15] in the zero charge limit.

Spectrum in the extremal limit

In the opposite limit for high charge, the results should conform to the extremal Reissner–Nordström (ERN) black hole
obtained for the beta coefficient squared, as expected:

\[ |\beta_{\omega'\omega}|^2 = \frac{4M^2 e^{-4M\pi\omega'}}{\pi^2\omega p} K_a\left(4M\sqrt{\omega\omega_p}\right)^2, \]  

(21)

in the correct limit, where \( a \equiv 1 + 4M\omega, \) and \( K_a \) is the modified Bessel function of the second kind. Indeed, taking the maximal charge limit \( Q^2 \rightarrow M^2 \) or \( r_+ \rightarrow r_s/2 = M \) of the integrand of Eq. (14) and then integrating over advanced time, the ERN spectrum is obtained. In the high frequency limit, this amounts to

\[ |\beta_{\omega'\omega}|^2 = \frac{4M^2}{\pi^2} \left| K_1\left(4M\sqrt{\omega\omega_p}\right)\right|^2, \]  

(22)

which, for a uniformly accelerated mirror \([17]\), is the spectrum with \( \kappa_{UA} \equiv 1/(2M) \), distinctly non-thermal \([3,4,18]\), as expected since the ERN black hole has “zero” (i.e. undefined) Hawking temperature \([19,20]\).

Spectrum in the late-time limit

Finally, one can check that at late time, thermal behavior is obtained for the beta coefficient squared, as expected:

\[ \lim_{\omega' \to 0} |\beta_{\omega'\omega}|^2 = \frac{1}{2\pi K_1(\omega/\kappa_+)} \frac{1}{e^{\omega/\kappa_+} - 1}, \]  

(23)

with temperature, \( T_+ = \kappa_+/(2\pi) \).

5 Conclusions

We have solved for the particle spectrum of the RN black hole by use of the moving mirror model solving for the beta Bogoliubov coefficients. In the limits of zero charge and maximum charge, the Schwarzschild and the ERN results are obtained, respectively. In the high frequency regime corresponding to late time the spectrum is thermal with temperature \( T_+ = \kappa_+/(2\pi) \).

The result demonstrates that during the formation of the RN black hole, charge inhibits the radiation of massless scalar neutral particles relative to an equal mass Schwarzschild black hole. The thermal count establishes the supposition (and confirms explicitly through particle production) that the distribution of particles from a RN black hole is the Planck spectrum.

Appendix A: Truncated method

The essential physics is actually encapsulated in the truncated trajectory:

\[ f(v)_{\text{Trun}} = v - \frac{1}{\kappa_+} \ln \frac{v}{2r_+}, \]  

(A1)

which results in a significant simplification. This motion is a good preliminary model for investigation of a spectrum that has the correct Schwarzschild limit and late-time limit. The corresponding exterior metric is

\[ ds_2^2 = \left(1 - \frac{1}{2\kappa_+ r}\right) du \, dv + r^2 \, d\Omega^2, \]  

(A2)

which has surface gravity \( \kappa_+ \) like the RN metric. But unlike the RN metric this is a vacuum solution, \( G_{\mu\nu} = 0 \) (so one could argue that \( Q \) is no longer the electric charge), with horizon at \( r = 1/(2\kappa_+) = r_s^2/(r_s - r_{-}) \neq r_{-} \). Plugging Eq. (A1) into Eq. (14) results in a spectrum that is simply,

\[ |\beta_{\omega'\omega}^{\text{Trun}}|^2 = \frac{\omega'}{2\pi K_1(\omega'/\kappa_+)} \frac{1}{e^{\omega'/\kappa_+} - 1}. \]  

(A3)

The Schwarzschild zero charge limit holds,

\[ \lim_{Q \to 0} |\beta_{\omega'\omega}^{\text{Trun}}|^2 = |\beta_{\omega'\omega}^{S}|^2, \]  

(A4)

and the late-time thermal limit also holds,

\[ \lim_{\omega' \to 0} |\beta_{\omega'\omega}^{\text{Trun}}|^2 = \frac{1}{2\pi K_1(\omega/\kappa_+)} \frac{1}{e^{\omega/\kappa_+} - 1}. \]  

(A5)

with temperature,
\[ T_+ = \frac{\kappa_+}{2\pi}, \quad (A6) \]

Since \( \kappa_+ < \kappa \), the particle production is mitigated by the presence of charge.
