REIDEMEISTER CLASSES IN SOME WEAKLY BRANCH GROUPS

EVGENIJ TROITSKY

Abstract. We prove that a saturated weakly branch group $G$ has the property $R_{\infty}$ (any automorphism $\phi : G \to G$ has infinite Reidemeister number) in each of the following cases:

1) any element of $\text{Out}(G)$ has finite order;
2) for any $\phi$ the number of orbits on levels of the tree automorphism $t$ inducing $\phi$ is uniformly bounded and $G$ is weakly stabilizer transitive;
3) $G$ is finitely generated, prime-branching, and weakly stabilizer transitive with some non-abelian stabilizers (with no restrictions on automorphisms).

Some related facts and generalizations are proved.

Introduction

Consider an automorphism $\phi : G \to G$ of a (countable discrete) group. The Reidemeister number $R(\phi)$ is the number of its Reidemeister or twisted conjugacy classes, i.e. the classes of the following equivalence relation: $g \sim hg\phi(h^{-1})$, $h, g \in G$. The Reidemeister class of an element $g$ we denote by $\{g\}_\phi$.

A group has the $R_{\infty}$ property if $R(\phi) = \infty$ for any automorphism $\phi : G \to G$. The problem of determining of groups having the $R_{\infty}$ property was raised by A.Fel’shtyn and co-authors in relation with an older conjecture by A.Fel’shtyn and R.Hill [5]: $R(\phi)$ is equal to the number of fixed points of the associated homeomorphism $\hat{\phi}$ of the unitary dual $\hat{G}$, if one of these numbers is finite. This conjecture is called TBFT (twisted Burnside-Frobenius theorem), because it generalizes to infinite groups and to the twisted case the classical Burnside-Frobenius theorem: the number of conjugacy classes of a finite group is equal to the number of equivalence classes of its irreducible representations. The question about TBFT formally has a positive answer for $R_{\infty}$ groups. So, the $R_{\infty}$ problem is in some sense complementary to the TBFT.

The TBFT conjecture was proved for finite, abelian and abelian-by-finite groups [5]. The further development, examples, counterexamples and modifications can be found in [11, 9, 10, 25, 26, 27].

The property $R_{\infty}$ was proved and disproved for many groups and the number of papers on the subject and related questions is too large to list all of them and we restrict ourselves to giving reference to several papers and bibliography overview therein: [24, 1, 19, 20, 12, 13, 21, 17, 2, 8]. Dynamical aspects of Reidemeister numbers are discussed in [4]. Some direct topological consequences of the property $R_{\infty}$ for Jiang-type spaces are discussed in [13].

In [6] the $R_{\infty}$ property was proved for a wide class of saturated weakly branch groups.

In the present paper we develop these results and prove in Theorem 2.2 that if any automorphism of a saturated weakly branch group $G$ is a composition of an inner automorphism

2000 Mathematics Subject Classification. 20E45; 20B35; 20F28; 20F65.

Key words and phrases. Reidemeister number, $R_{\infty}$-group, twisted conjugacy class, residually finite group, weakly branch group.

and of a finite order automorphism, then $G$ has the property $R_\infty$. In particular, this theorem holds for the Grigorchuk group and for the Gupta-Sidki group. In some specific cases the result can be obtained from [17].

We introduce the property WST (Definition 1.7) and prove that if for any automorphism $\phi$ of a saturated weakly branch WST group $G$, induced by an automorphism $t$ of the tree, i.e. $\phi(g) = tgt^{-1}$, restrictions of $t$ on levels have a uniformly bounded number of orbits, then $G$ has the property $R_\infty$ (Theorem 3.3).

In Theorem 4.2 we prove the $R_\infty$ property without any restrictions on the structure of the automorphism group of a finitely generated saturated weakly branch WST group $G$, but with the restriction on branching numbers to be prime and with an additional restriction on stabilizers.

We prove that a saturated weakly branch group on a spherically symmetric tree, such that any level stabilizer contains an odd permutation at some level, is an $R_\infty$ group (Theorem 5.2).

ACKNOWLEDGEMENT: The author is indebted to A. Fel’shtyn and the MPIM for helpful discussions in the Max-Planck Institute for Mathematics (Bonn) in February, 2017, to V. Manuilov for useful suggestions, and to A. Jaikin-Zapirain for a bibliography reference.

1. Preliminaries

First, we recall some necessary facts about Reidemeister classes.

**Lemma 1.1.** Any Reidemeister class of $\phi$ is formed by some $\phi$-orbits.

**Proof.** Indeed, $\phi(g) = g^{-1}g\phi(g)$. \qed

**Definition 1.2.** Denote by $\tau_g$ the inner automorphism: $\tau_g(x) = g\phi(g)$.

From the equality

$$xy\phi(x^{-1})g = x(yg)g^{-1}\phi(x^{-1})g = x(yg)(\tau_g \circ \varphi)(x^{-1})$$

we immediately obtain the following statement.

**Lemma 1.3.** A right shift by $g \in G$ maps Reidemeister classes of $\phi$ onto Reidemeister classes of $\tau_g \circ \varphi$. In particular, $R(\tau_g \circ \phi) = R(\phi)$.

**Lemma 1.4 ([7, Prop. 3.4]).** Suppose, $\phi$ is an automorphism of a finitely generated residually finite group. Let $R(\phi) = r < \infty$. Then the number of fixed elements of $\phi$ is bounded by a function depending only on $r$.

Now we pass to groups acting on trees and give some known and new definitions and facts.

Let $T$ be a spherically symmetric rooted tree. This means that all vertexes of the same level have the same number of immediate descendants (branching index).

Denote by $D(v)$ the set of immediate descendants of a vertex $v \in T$.

A group $G$ acting faithfully on a rooted tree is a weakly branch group, if for any vertex $v$ of $T$, there exists an element of $G$ which acts nontrivially on the subtree $T_v$ with the root vertex $v$ and trivially outside this subtree. In other words, the rigid stabilizer $\text{Rist}_v$ of any vertex $v$ is non-trivial.

Evidently a faithful tree group is residually finite.
We will denote by $\text{St}(v)$ the \textit{stabilizer of a vertex} $v \in T$; and by $\text{St}_j$ the \textit{stabilizer of level} $L_j$, i.e. $\text{St}_j = \cap_{v \in L_j} \text{St}(v)$.

A group $G$ is \textit{saturated} if, for every positive integer $n$, there exists a characteristic subgroup $H_n \subset G$ acting trivially on the $n$-th level of $T$ and level transitive on any subtree $T_v$ with $v$ in the $n$-th level.

**Theorem 1.5** ([18]). Suppose, $G$ is a saturated weakly branch group on a tree $T$. Then its \textit{automorphism group} $\text{Aut} G$ coincides with the normalizer of $G$ in the full group of isometries $\text{Iso}(T)$ of the rooted tree $T$: every automorphism $\phi$ of the group $G$ is induced by the conjugation by an element $t$ from the normalizer and the centralizer of $G$ in $\text{Iso}(T)$ is trivial.

**Definition 1.6.** For a group $G$ acting on $T$ and any vertex $v \in T$ denote by $G_{\{v\}}$ the subgroup of all elements $g \in G$ fixing $v$ and all vertexes of $T$ from the next level, except of immediate descendants of $v$.

In other words, if $v \in L_j$, then

$$G_{\{v\}} = \bigcap_{w \in L_j, w \neq v} \bigcap_{u \in D(w)} \text{St}(u)$$

Thus,

$$\text{Rist}_v \subset G_{\{v\}} \subset \text{St}_j$$

**Definition 1.7.** We call a group $G$ acting on $T$ \textit{weakly stabilizer transitive (WST)} if for any vertex $v$ one can find a vertex $v_0 \in T_v$ such that $G_{\{v_0\}}$ acts transitively on immediate descendants of $v_0$.

**Remark 1.8.** If $G$ acts level-transitively, then $G_{\{v\}}$ are pairwise isomorphic for $v$ from the same level. Also, they pairwise commute and we can introduce the following well-defined group $\Gamma_{\{i\}}$.

**Definition 1.9.** Denote

$$\Gamma_{\{i\}} := \prod_{v \in L_{i-1}} p_i(G_{\{v\}}),$$

where $p_i : G \to G/\text{St}_i$ is the natural projection.

Let $t$ be an automorphism of a tree $T$. Let $\text{Orb}_i(t)$ be the number of orbits of $t$ at the level $L_i$. Evidently,

1) $\text{Orb}_i(t)$ is a not-decreasing function of $i$;
2) a fixed vertex of $t$ may be only a successor of a fixed vertex;
3) if there is a fixed vertex at the level $i+1$, then $\text{Orb}_{i+1}(t) > \text{Orb}_i(t)$.

So, we have two possibilities:

(a) $\text{Orb}_i(t) \to \infty$ as $i \to \infty$;
(b) $\text{Orb}_i(t)$ is bounded. In this case, there is no fixed vertices starting some level, by 3) above.

Finally, we will need the following statement from the Galois theory (see, e.g. [3, Sect. 3.5]):

**Lemma 1.10.** A solvable transitive subgroup of the symmetric group $S_p$, where $p$ is prime, is isomorphic either to $\mathbb{Z}_p$, or to $\mathbb{Z}_p \rtimes \mathbb{Z}_{p-1}$. In particular, it is either abelian, or contains an odd permutation (a generator of $\mathbb{Z}_{p-1}$).
2. Finite order automorphisms and around

Lemma 2.1. Let \( \phi : G \to G \) be an automorphism of order \( n < \infty \) of a weakly branch group with \( \phi(g) = tgt^{-1} \). Then there exists \( j_0 \) such that for any \( j \geq j_0 \) there exists an element \( g_j \in \text{St}_j \) and a number \( i > j \) such that \( \{g_j\}_i \cap \text{St}_i = \emptyset \).

Proof. It is sufficient to find an element \( g_j \) such that \( hg_j h^{-1} t^{-1} \neq e \) at the level \( L_i \) for any \( h \in G \), or equivalently

\[
(1) \quad g_j t \neq h^{-1} t h.
\]

By the condition, \( t \) has at some level an orbit of length \( n \), and does not have a longer orbit. Take for \( j_0 \) the first time when \( t \) has on \( L_{j_0} \) an orbit of length \( n \). Then the orbits of successors also will have the length \( n \). Consider any \( j \geq j_0 \) and an orbit of length \( n \) in \( L_j \). Let \( v_0 \in L_j \) be a vertex from this orbit. Using the weak branching property we can find a non-trivial element \( g_j \in \text{Rist}(v_0) \). Let \( i \) be the first level where \( g_j \) acts non trivially, say at \( v \in T_v \) (see Fig. 1). Then

\[
(2) \quad (g_j t)^n(v) = g_j t^n(v) = g_j(v) \neq v,
\]

because the \( t \)-orbit of \( v \) has the form \( v, t(v), \ldots, t^{n-1}(v), t^n(v) = v \) and \( t(v), \ldots, t^{n-1}(v) \notin T_v \) implying \( gt(v) = t(v), \ldots, gt^{n-1}(v) = t^{n-1}(v) \). So, \( g_j t \) has an orbit of length \( n \) and can not be conjugate to \( t \) at the level \( L_i \). We obtain (1). \( \square \)

Theorem 2.2. Suppose, \( G \) is a saturated weakly branch group and each automorphism from \( \text{Out}(G) \) is of finite order. Then \( G \) has the \( R_\infty \) property.
Proof. By Lemma 1.3 it is sufficient to verify $R(\phi) = \infty$ for some $\phi$ of finite order $n$.

By Theorem 1.5 $\phi(g) = tgt^{-1}$ for an automorphism $t$ of the tree. Then Lemma 2.1 gives inductively an infinite sequence of representatives of distinct Reidemeister classes. Thus $R(\phi) = \infty$. $\square$

Example 2.3. The most studied branch groups – the Grigorchuk group [14] and the Gupta-Sidki group [16] – have outer automorphisms of finite order [15, 23].

Example 2.4. A more evident example is the group of all isometries of a symmetric rooted tree. In this case all automorphisms are inner.

3. Finite number of orbits

Now we consider the opposite case, when the number of orbits $t$ on $L_i$ is uniformly bounded. We will need to restrict ourselves to the WST case.

Lemma 3.1. Let $\phi : G \to G$ be an automorphism of a WST group with $\phi(g) = tgt^{-1}$, where $t$ is an automorphism of the tree $T$. Suppose, $t$ satisfies (b) above, namely, $\max_i \text{Orb}_i(t) = M < \infty$. Then there exists $j_0$ such that for any $j \geq j_0$ there exists an element $g_j \in \text{St}_j$ and a number $i > j$ such that $\{g_j\}_\phi \cap \text{St}_i = \emptyset$.

Proof. Let $j_0$ be the length of stabilization of the number of orbits, i.e., $\text{Orb}_{j_0-1}(t) < M$ and $\text{Orb}_{j_0}(t) = M$, hence $\text{Orb}_j(t) = M$ for any $j \geq j_0$. Note that the lengths of orbits of $t$ at next levels, are the multiples of lengths of orbits on $L_{j_0}$ (with the coefficient equal to the appropriate product of branching numbers) and an orbit of smallest length (not unique generally) lies under a smallest orbit on $L_{j_0}$.

Now take an arbitrary $j \geq j_0$ and consider an orbit of $t$ of the smallest size on $L_j$. Let $v$ be a vertex from this orbit, and find by the WST property an element $v_0 \in T_v$, $v_0 \in L_{i-1}$ for some $i$, with a transitive action of $G_{\{v_0\}}$ on its immediate successors. Let $v_1$ be one of these successors. Then, as it was explained, its $t$-orbit has the smallest length among the orbits on $L_i$. This length is equal to $m \cdot b$, where $m$ is the length of $t$-orbit of $v_0$ and $b$ is the branching number of $v_0$. Choose $g_j \in G_{\{v_0\}}$ such that $g_j t^m(v_1) = v_1$ (see Fig. 2). By the definition of $G_{\{v_0\}}$,

$$g_j t(v_1) = t(v_1), \quad (g_j t)^2(v_1) = t^2(v_1), \ldots \quad (g_j t)^m(v_1) = g_j t^m(v_1) = v_1.$$ 

Hence, the smallest length of a $(g_j t)$-orbit on $L_i$ is $m < m \cdot b$ = the smallest length of a $t$-orbit on $L_i$. Thus, $g_j t$ and $t$ can not be conjugate and we arrive to (1) and the same argument as in the beginning of the proof of Lemma 2.1, completes the proof. $\square$

Remark 3.2. By Lemma 1.1 $R(\phi) < \infty$, if the number of $\phi$-orbits is finite. But the number of $\phi$-orbits in $G$ is rather weakly related to the number of $t$-orbits on $T$. For example, for $t = \text{Id}$, this depends on “how saturated $G$ is”.

Similarly to the proof of Theorem 2.2, one can deduce from Lemma 3.1 the following statement.

Theorem 3.3. If a saturated weakly branch group $G$ is a WST group and each its non-trivial outer automorphism has the properties from Lemma 3.1, then $G$ is an $R_\infty$ group.

Example 3.4. We do not expect interesting examples of groups here, moreover, we need the results of this section mostly as a tool for proofs with using for some automorphisms in the next section (case b) below).

Nevertheless, Example 2.4 works here too.
Lemma 4.1. Let $\phi : G \to G$ be an automorphism of a group $G$ acting level-transitively on a spherically symmetric tree $T$, with $\phi(g) = tgt^{-1}$. Suppose,

1. $G$ is finitely generated;
2. $G$ is a WST group;
3. moreover, for an infinite subsequence $\{i_k\}$ of the sequence of levels, arising as transitivity levels in the definition of WST, the corresponding group $\Gamma_{\{i\}}$ (see Def. 1.9) is not abelian;
4. branching numbers are prime (may be distinct for distinct levels).

Suppose, $R(\phi) < \infty$. Then there exists $j_0$ such that for any $j \geq j_0$ there exists an element $g_j \in \text{St}_j$ and a number $i > j$ such that $\{g_j\}_\phi \cap \text{St}_i = \emptyset$.

Proof. As in the proof of Lemma 2.1, it is sufficient to find an element $g_j \in \text{St}_j$ such that at the level $L_i$ for any $h \in G$

\begin{equation}
(3) \quad g_j \neq h^{-1}tht^{-1}.
\end{equation}

Consider two cases:

a) $\text{Orb}_i(t) \to \infty$;

b) $\text{Orb}_i(t)$ is bounded.

Case a). Since $R(\phi) < \infty$ and $G$ is finitely generated, by Lemma 1.4 the number of $\phi$-fixed elements for the quotient $G/\text{St}_i$ is strictly less $\text{Orb}_{i-1}(t)$ at each level $i$ greater some $j_0$. 

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure2.png}
\caption{Figure 2.}
\end{figure}
Now for any \( j > j_0 \), let \( i - 1 > j \) be the number of a level with transitive action of \( G_{\{v\}} \) for any \( v \in L_{i-1} \) (see Remark 1.8) such that \( \Gamma_{\{i\}} \) is not abelian.

Each of the above-mentioned \( \phi \)-fixed elements (except of \( e \)) acts non-trivially at some vertex \( w_s \). Thus an element, which fixes these vertexes, is not \( \phi \)-fixed. Hence there exists \( v_0 \in L_{i-1} \) such that for any \( v \) in its \( t \)-orbit, \( p_i(G_{\{v\}}) \) does not contain \( \phi \)-fixed points, where \( p_i: G \to G/St_i \). Suppose, the \( t \)-orbit of \( v_0 \) has some length \( k \) (\( k = 1 \) can occur in particular).

Then \( p_i G_{\{t^m(v_0)\}} = t^mp_i G_{\{v_0\}} t^{-m} \), \( m = 0, 1, \ldots, k - 1 \).

Evidently, elements of these groups commute, and we can form a group

\[ \Gamma := p_i(G_{\{v_0\}}) \cdots p_i G_{\{k-1(v_0)\}} \]

with an action of \( \phi \). Each \( \gamma \in \Gamma \) acts trivially on all \( w_s \). Hence, \( \Gamma \) has no nontrivial \( \phi \)-fixed elements. So, \( \Gamma \) is a subgroup with a fixed-point-free automorphism \( \phi \). Then it is solvable by [22].

Hence, its subgroup \( p_i(G_{\{v_0\}}) \) is also solvable. It is a transitive subgroup of the symmetric group \( S_p \), where \( p \) is the prime branching number for vertexes from \( L_{i-1} \). Then, by Lemma 1.10, it is either abelian, or contains an odd permutation \( p_i(g_j) \not\in A_p, g_j \in G_{\{v_0\}} \). In the first case, \( \Gamma_{\{i\}} \) is abelian in contradiction with the supposition. In the second case, \( g_j \) is trivial on \( L_i \) except the successors of \( v_0 \). So it is an odd permutation on the entire \( L_i \), while \( h^{-1}th^{-1} \) is an even one. This gives (3).

**Case b)**. This case immediately follows from Lemma 3.1.

Similarly to the proof of Theorem 2.2 we obtain from Lemma 4.1 the following statement.

**Theorem 4.2.** Suppose, \( G \) is a finitely generated saturated weakly branch WST group on a spherically symmetric tree with prime branching numbers and an infinite sequence of non-abelian \( \Gamma_{\{i\}} \) (i.e. satisfying the suppositions of Lemma 4.1). Then \( G \) is an \( R_\infty \) group.

**Remark 4.3.** Reasonable examples will be given in the next section for a version of this statement, namely Theorem 5.2.

## 5. Some generalizations

Evidently the above statements can be easily extended to some more general cases (with more complicated formulations).

For example, Theorem 2.2 can be evidently generalized in the following way.

**Theorem 5.1.** Suppose, \( G \) is a weakly branch group and each automorphism from \( \text{Out}(G) \) is of finite order and defined by an automorphism of the tree. Then \( G \) has the \( R_\infty \) property.

Now we will give another version of Theorem 4.2.

**Theorem 5.2.** Suppose, \( G \) is a saturated weakly branch group on a spherically symmetric tree, such that for any \( j \), \( St_j \) contains an element \( g_j \) defining an odd permutation at some level \( j_0 > j \). Then \( G \) is an \( R_\infty \) group.

**Proof.** Indeed, (3) keeps, because \( h^{-1}th^{-1} \) is an even permutation and \( g_j \) is an odd permutation at the level \( j_0 \).

**Example 5.3.** The full isometry group as in Example 2.4 satisfies the conditions of Theorem 5.2.
Example 5.4. Consider a saturated weakly branch group $G$ and consider a group $\Gamma$ generated by $G$ and an infinite series of isometries $g_j$, e.g., transpositions of two neighbouring elements at level $L_{j+1}$ and somehow defined at their successors. Then $\Gamma$ satisfies the conditions of Theorem 5.2.
