Abstract

We have derived the hierarchy of soliton equations associated with the untwisted affine Kac-Moody algebra $D_4^{(1)}$ by calculating the corresponding recursion operators. The Hamiltonian formulation of the equations from the hierarchy is also considered. As an example we have explicitly presented the first non-trivial member of the hierarchy, which is an one-parameter family of mKdV equations. We have also considered the spectral properties of the Lax operator and introduced a minimal set of scattering data.

1 Introduction

After the discovery of the inverse scattering method (ISM) in 1967 by the Princeton group of Gardner, Greene, Kruskal and Miura [27], the study of soliton equations and the related integrable nonlinear evolution equations (NLEEs) became one of the most active branches of nonlinear science. In this pioneering paper, the Korteveg-de Vries (KdV) equation was exactly integrated using the ISM. One year later, Peter Lax presented a method, which would later be instrumental in the search of new integrable equations different from the KdV [53]. This started numerous attempts to extend the range of application of the ISM to other equations.

Three years had passed, when Gardner started the canonical approach to the NLEEs. He was the first to realize that the KdV equation can be written in a Hamiltonian form [26]. Soon after that, Zakharov and Faddeev proved that KdV equation is a completely integrable Hamiltonian system [67] and Wadati solved the modified Korteweg-de Vries (mKdV) equation [66].

This explosion of interest in the soliton science led to the discovery of a completely new world of unknown before integrable equations together with methods and techniques for finding their exact solutions. We should mention some of those methods and techniques, starting with the fundamental analytic solution (FAS), which was introduced by Shabat [63]. Within this approach one can show that the ISM is equivalent to a multiplicative
Reimman-Hilbert problem (RHP), which is the basis for the dressing method invented by Zakharov and Shabat [69, 70]. Another important result was derived by Ablowitz, Kaup, Newell and Segur [2]. They showed that the ISM can be interpreted as a generalized Fourier transform. This approach is based on the Wronskian relations, which are basic tools for the analysis of the mapping between the potential and the scattering data. They allow the construction of the “squared solutions” of the Lax operator, which form a complete set of functions and play the role of the generalized exponentials (see [30, 34, 33] and the references therein). Another powerful technique we should mention here is that of the so called recursion operators. This method has in principal a long history but the application to the NLEEs started in [28] (see also [54] and [47]) where with the help of the recursion operator KdV equation was written in a compact form. Within the study of the Nonlinear Schrödinger (NS) equation, considered in the rapidly decreasing case and using the requirement that the squared Jost solutions of the auxiliary linear problem are its eigenfunctions, the recursion operator was first introduced in [2]. The case of the general matrix linear differential operator of the first order was studied in [57]. We should also mention the Tzitzeica equation [65, 66], which was rediscovered as a soliton equation at the end of the 1970s. Its Lax pair was discovered by Mikhailov [55] who demonstrated, that Tzitzeica equation has a hidden $\mathbb{Z}_3$-symmetry, which becomes evident at the Lax pair level. This led Mikhailov to the discovery of the reduction group, an important concept in the Lax representation of soliton equations. He also solved the family of 2-dimensional Toda field theories (of which Tzitzeica equation is a particular example) by using the dressing method. The further development of all these methods and techniques and also their numerous applications can be found for example in [1, 3, 8, 10, 16, 20, 52, 58, 59, 29] and more recently in [32, 35, 36]. For a brief introduction to the very intriguing history of the solitons and the ISM see, for instance, [4, 56] and also [8, 16, 58].

The theory of soliton equations deals with a class of nonlinear partial differential equations that admit exact solutions. That is why, it is natural to study the soliton equations from a group-theoretical point of view and to uncover the algebraic structures, which are behind them. Investigations clarifying the algebraic structure of several classes of NLEEs were, for the first time, started in the early 1980s in the Research Institute for Mathematical Sciences by the Kyoto group. Namely, M. Sato and Y. Sato in their studies discovered the very remarkable fact that there is a transitive action of an infinite-dimensional group on the manifold of solutions of the Kadomtsev-Petviashvili (KP) hierarchy and the corresponding Lie algebra is $\mathfrak{gl}(\infty)$ [60, 61].

Another very important investigation, which shows deep and fundamental links between NLEEs and infinite-dimensional Lie groups and Lie algebras was done by Drinfeld and Sokolov [17, 18]. In their papers, starting from an affine Kac-Moody algebra and applying the method of Hamiltonian reduction, they obtain a one-parameter family of Poisson brackets, which are defined on some infinite-dimensional Poisson manifold, and construct an integrable hierarchy of bi-Hamiltonian equations. In their studies they found most of the mKdV equations related to the low dimensional cases, for example, when the
affine Kac-Moody algebra is $A_1^{(1)} \simeq \widehat{sl}_2$ the resulting equation is the well-known mKdV equation. Within this scheme, Casati, Della Vedova and Ortenzi [12] found in an explicit form the hierarchy, which is related to the affine Kac-Moody algebra $G_2^{(1)}$ together with the bi-Hamiltonian structure of the obtained soliton equations.

These investigations were followed by Date, Jimbo, Kashiwara and Miwa with a sequence of seminal papers [13] (see also [19] and references there in) in which the representation theory of affine Kac-Moody algebras is used to obtain KP and KdV hierarchies, for example, the KdV and KP hierarchies are related correspondingly to the affine Lie algebras $A_1^{(1)}$ and $A_\infty$. A very important side of these investigations is that they put on very general grounds the use of the theory of affine Lie algebras and their corresponding Lie groups in finding the hidden symmetries of soliton equations.

The relation between infinite-dimensional Lie algebras, and their groups and soliton equations has inspired a huge number of further investigations in which this link has been widely extended and generalized in many different senses and directions. In particular, Segal and Wilson elaborated a construction, which associates with every solution of the KdV equation a point of some infinite-dimensional Grassmannian [62]. They show that the geometry of the Grassmannian reflects to the properties of the exact solutions. Within this powerful approach the explicit algebro-geometric solutions are naturally described and the geometrical meaning of the $\tau$-function is clarified. Kac and Wakimoto [51] constructed a scheme in which vertex operator representations of some affine Lie algebras are used to obtain hierarchies of NLEEs. In the papers [9, 45] Burroughs, de Groot, Hollowood and Miramontes used a general approach, with the help of which they constructed integrable hierarchies of NNLEs, which in turn are related to untwisted Kac-Moody algebras. The generalized KdV hierarchies of Drinfeld and Sokolov can be naturally included within this approach and are obtained as some special cases of the general scheme. They also include most of the generalizations of the original Drinfeld-Sokolov construction available in the literature. The extent of this class of hierarchies by means of (matrix) pseudo-differential operators has been investigated by Fehér, Harnad, Marshall, Delduc and Gallot [14, 15, 22, 23] (see also [5]). Their construction and its generalizations provide a systematic approach to the study and classification of many integrable hierarchies described by means of pseudo-differential Lax operators. For a brief but very informative review of some of these results see for example [21]. An equivalent construction to the generalized Drinfeld-Sokolov hierarchies was proposed by Feigin and Frenkel [24, 25]. In this approach, instead of the Hamiltonian flows of the mKdV hierarchy, as main technical tool are introduced properly chosen vector fields defined on the space of jets of the potential of the Lax operator, which potential in turn belongs to the Cartan subalgebra of the corresponding affine Kac-Moody algebra. Enriquez and Frenkel [19], recently after the introducing the approach of Feigin and Frenkel, proved that this construction is equivalent to that proposed previously by Drinfeld and Sokolov.

The present paper can be considered as a natural continuation on the investigations of the relation between Kac-Moody algebras and integrable equations started in our previous
works [37, 38, 39, 40]. In particular, there we have analyzed family of integrable nonlinear partial differential equations associated to the untwisted affine Kac-Moody algebras $A_r^{(1)}$, which represent the third member of the obtained hierarchy. We also started investigations concerning the affine Kac-Moody algebra $D_4^{(1)}$.

The $D_4 \simeq so(8)$ is a quite interesting algebra, actually it is unique among the simple Lie algebras, because $D_4$ is the only algebra with an $S_3$ symmetry of its Dynkin diagram. It is also the only simple Lie algebra that has 3 as a double-valued exponent. For these reasons, the main purpose of this paper is to derive directly in an explicit way the hierarchy of soliton equations related to the untwisted affine Kac-Moody algebra $D_4^{(1)}$. This is an alternative approach to the one used in [17, 18]. In particular, we will pay special attention to the one-parameter family of mKdV equations. We also formulate the spectral properties of the Lax operators as well as the FAS of the system.

The paper is organized as follows. In Section 2 we give some basic facts concerning Kac-Moody algebras and present an explicit way of constructing a basis in the algebra $D_4^{(1)}$. In Section 3 the Lax pair corresponding to the hierarchy is defined and then analyzed and the recursion operators giving the hierarchy of soliton equations are derived. In Section 4, following [17, 18], we give the Hamiltonian formulation of the obtained soliton equations along with the general formula for the corresponding Hamiltonians. In Section 5 we derive explicitly the first non-trivial member of the hierarchy, which is a one-parameter family set of mKdV type equations. In Section 6 we formulate the spectral properties of the Lax operators and the corresponding RHP. We construct two minimal sets of scattering data and prove that they allow one to reconstruct both the scattering matrix and the potential of the Lax operator. Section 7 contains concluding remarks. In the Appendix we present some properties of the simple Lie algebra $D_4$ and show an explicit construction of the dihedral realization of the Coxeter automorphism. Here, we also give the explicit form of the basis of $D_4^{(1)}$, which is used in the calculations. We also show the explicit calculation of $ad^{-1}_J$, a step that is required for the calculation of the recursion operators.

## 2 Preliminaries

A Lie algebra is called simple if it is non-Abelian and contains no nontrivial ideals. A semisimple Lie algebra is the direct product of finite number of simple algebras. We will consider algebras over the field of complex numbers $\mathbb{C}$. Let $\mathfrak{g}$ be a finite-dimensional simple Lie algebra. By $ad_X$ we denote the linear operator defined by

$$ad_X(Y) = [X, Y], \quad X, Y \in \mathfrak{g}. \quad (1)$$

\footnote{For a comprehensive treatment concerning finite-dimensional Lie algebras, as well as infinite-dimensional Lie algebras of Kac-Moody type, see [11, 44, 45, 49, 50]. A collection of articles can be found in [64].}
This operator has a kernel and can only be inverted on its image. We denote that inverse by $\text{ad}_X^{-1}$. If $X$ is diagonalizable then $\text{ad}_X^{-1}$ can be expressed as a polynomial of $\text{ad}_X$. Let $\langle \cdot, \cdot \rangle$ be the Killing-Cartan form on $\mathfrak{g}$, which is defined by

$$\langle X, Y \rangle = \text{tr} (\text{ad}_X \text{ad}_Y).$$  \hspace{1cm} (2)

It can be shown that for the typical representation of a simple Lie algebra we have

$$\langle X, Y \rangle = \text{tr} (XY).$$  \hspace{1cm} (3)

Let $\varphi$ be an automorphism of $\mathfrak{g}$ of finite order. If it is of the form

$$\varphi(X) = e^F X e^{-F}$$  \hspace{1cm} (4)

for some generator $F$ then it is called an inner automorphism. Every automorphism that is not inner is an outer automorphism. The set of outer automorphisms of $\mathfrak{g}$ is equivalent, up to a conjugation with an inner automorphism, to the symmetries of the Dynkin diagram of $\mathfrak{g}$. Every finite-order automorphism $\varphi$ introduces a grading in $\mathfrak{g}$ by

$$\mathfrak{g} = \bigoplus_{k=0}^{s-1} \mathfrak{g}^{(k)},$$  \hspace{1cm} (5)

such that

$$\varphi(X) = \omega^k X, \quad \omega = \exp \left( \frac{2\pi i}{s} \right), \quad \forall X \in \mathfrak{g}^{(k)},$$  \hspace{1cm} (6)

where $s$ is the order of $\varphi$. The grading condition also holds

$$[\mathfrak{g}^{(k)}, \mathfrak{g}^{(l)}] \subset \mathfrak{g}^{(k+l)},$$  \hspace{1cm} (7)

where $k + l$ is taken modulo $s$.

If $\mathfrak{g}$ is a finite-dimensional Lie algebra over $\mathbb{C}$ then

$$\mathfrak{g}[\lambda, \lambda^{-1}] = \left\{ \sum_{i=n}^{m} v_i \lambda^i : v_i \in \mathfrak{g}, n, m \in \mathbb{Z} \right\},$$  \hspace{1cm} (8)

$$f(\lambda) = \left\{ \sum_{i=0}^{m} f_i \lambda^i : f_i \in \mathfrak{g}, m \in \mathbb{Z} \right\}.$$

There is a natural Lie algebraic structure on $\mathfrak{g}[\lambda, \lambda^{-1}]$. Let $\varphi$ be a finite-order automorphism of $\mathfrak{g}$, then

$$L(\mathfrak{g}, \varphi) = \left\{ f \in \mathfrak{g}[\lambda, \lambda^{-1}] : \varphi(f(\lambda)) = f(\lambda e^{\frac{2\pi i}{n}}) \right\}.$$  \hspace{1cm} (9)

$L(\mathfrak{g}, \varphi)$ is a Lie subalgebra of $\mathfrak{g}[\lambda, \lambda^{-1}]$. If $\mathfrak{g}$ is simple then $L(\mathfrak{g}, \varphi)$ is called a Kac-Moody algebra. It is obvious that Kac-Moody algebras are graded algebras. Note that commonly
the central extension of $L(\mathfrak{g}, \varphi)$ is called a Kac-Moody algebras. The definition given above is the one used in [17, 18].

The automorphism $\varphi$ is conjugate to some minimal-order element from the conjugacy class of outer automorphisms of $\mathfrak{g}$. The order of that element is called the height of $L(\mathfrak{g}, \varphi)$.

As is shown in [50], two Kac-Moody algebras $L(\mathfrak{g}_1, \varphi_1), L(\mathfrak{g}_2, \varphi_2)$ are equivalent if $\mathfrak{g}_1$ is isomorphic to $\mathfrak{g}_2$, and $\varphi_1$ is conjugate to $\varphi_2$.

An automorphism $C$ of a simple Lie algebra is said to be a Coxeter automorphism if the eigen-space that corresponds to an eigenvalue 1 is Abelian and $C$ is of minimal order. The order of $C$ is called the Coxeter number of the algebra.

In this paper we will consider the equations related to $L(D_4, C)$, where $C$ is a Coxeter automorphism conjugate to the identity. We will use the standard notation $D_4^{(1)}$ [11]. The Coxeter number of $D_4^{(1)}$ is 6 and its exponents are $1, 3, 5, 3$ [17, 11]. The Coxeter automorphism is realized as

$$C(X) = cXc^{-1},$$

where $c$ is given in the appendix (see [50]). It introduces a grading in $D_4$ via (6). A basis compatible with this grading is given by averaging the Cartan-Weyl basis over the action of the Coxeter automorphism

$$E_i^{(k)} = \sum_{s=0}^{5} \omega^{sk}C^s(E_{\alpha_i}), \quad H_j^{(k)} = \sum_{s=0}^{5} \omega^{sk}C^s(H_j).$$

Note that $H_j^{(k)}$ is non-vanishing only if $k$ is an exponent. Since 3 is a double-valued exponent, $\mathfrak{g}^{(3)}$ will contain two Cartan elements. The explicit form of the basis is given in the appendix.

### 3 Lax pair and recursion operators

We will derive the hierarchy of equations related to a Lax pair that is subject to a $Z_h$ reduction [55]

$$L\psi \equiv i\frac{\partial \psi}{\partial x} + U(x, t, \lambda)\psi = 0,$$

$$M\psi \equiv i\frac{\partial \psi}{\partial t} + V(x, t, \lambda)\psi = \psi\Gamma(\lambda),$$

where the potentials must satisfy

$$C(U(x, t, \lambda)) = U(x, t, \omega \lambda), \quad C(V(x, t, \lambda)) = V(x, t, \omega \lambda).$$

Here $C$ is a Coxeter automorphism and $\omega = e^{\frac{2\pi i}{6}}$. This implies that the potentials are elements of the Kac-Moody algebra $D_4^{(1)}$. A Lax pair compatible with the above reduction
is given by

\[ L = i\partial_x + Q(x,t) - \lambda J, \]
\[ M = i\partial_t + \sum_{k=0}^{n-1} \lambda^k V^{(k)}(x,t) - \lambda^n K, \]  \hspace{1cm} (14)

where

\[ Q(x,t) \in \mathfrak{g}^{(0)}, \quad V^{(k)}(x,t) \in \mathfrak{g}^{(k)}, \quad K \in \mathfrak{g}^{(n)}, \quad J \in \mathfrak{g}^{(1)}. \]  \hspace{1cm} (15)

For simplicity, we assume that \( n \leq h \) and \( n \) is an exponent of \( D_4^{(1)} \). If \( n \) is not an exponent the resulting equations are trivial and if \( n > h \) then every index should be understood modulo \( h \). The explicit form of the potential \( Q \) is

\[ Q(x,t) = \sum_{i=1}^{r} q_i(x,t) \mathcal{E}_i^{(0)}. \]  \hspace{1cm} (16)

To simplify the notation we will omit writing any explicit dependence on \( x \) or \( t \).

The elements \( J \) and \( K \) are some properly chosen constant matrices. In our case

\[ J = \frac{1}{2} \mathcal{H}_1^{(1)} = \text{diag}(1, \omega, \omega^5, 0, 0, -\omega^5, -\omega, -1) \]  \hspace{1cm} (17)

and \( K \) is chosen so that \([J, K] = 0\).

Our choice of \( J \) fixes the inverse of \( \text{ad}_J \) to (for more details, see the Appendix)

\[ \text{ad}_J^{-1} = \frac{1}{27} (26 \text{ad}_J^5 + \text{ad}_J^{11}). \]  \hspace{1cm} (18)

The Lax pair must commute, i.e.

\[ [L, M] = 0 \]  \hspace{1cm} (19)

for every \( \lambda \). This implies the following recursion relations

\[ \lambda^{n+1} : \quad [J, K] = 0, \]
\[ \lambda^n : \quad [J, V^{(n-1)}] + [Q, K] = 0, \]
\[ \lambda^s : \quad i \frac{\partial V^{(s)}}{\partial x} + [Q, V^{(s)}] - [J, V^{(s-1)}] = 0, \]
\[ \lambda^0 : \quad -i \frac{\partial Q}{\partial t} + i \frac{\partial V^{(0)}}{\partial x} + [Q(x,t), V^{(0)}] = 0. \]  \hspace{1cm} (20)

Each element splits into "orthogonal" and "parallel" parts

\[ V^{(s)} = V^{(s)}_\perp + V^{(s)}_\parallel, \quad \text{ad}_J \left( V^{(s)}_\parallel \right) = 0, \]
\[ V^{(s)}_\parallel(x,t) = \begin{cases} 0 & \text{if } s \text{ is not an exponent}, \\ \sum_{j=1}^{k} c_{s,j}^{-1} \mathcal{H}_j^{(s)} \left( V^{(s)}, \mathcal{H}_j^{(h-s)} \right) & \text{if } s \text{ is an exponent}, \end{cases} \]  \hspace{1cm} (21)
where $c_{s,j} = \langle \mathcal{H}_j^{(s)}, \mathcal{H}_j^{(h-s)} \rangle$ and $k$ is the multiplicity of the exponent. From (20) we can see that

$$V_\perp^{(s-1)} = \text{ad}_j^{-1} \left( i \frac{\partial V^{(s)}}{\partial x} + [Q, V_\perp^{(s)}] + [Q, V_\parallel^{(s)}] \right),$$

(22)

$$i \frac{\partial V^{(s)}}{\partial x} = -[Q, V_\perp^{(s)}].$$

Integrating the second equation we get

$$V_\parallel^{(s)} = i \partial_x^{-1} [Q, V_\perp^{(s)}] = i \sum_{j=1}^k c_{s,j}^{-1} \mathcal{H}_j^{(s)} \partial_x^{-1} \left( [Q, V_\perp^{(s)}], \mathcal{H}_j^{(h-s)} \right),$$

(23)

where we have set any constants of integration to be equal to zero. Thus the solution of the recurrent relations takes the form

$$V^{(n-1)} = -\text{ad}_j^{-1} [Q, K],$$

$$V_\perp^{(s-1)} = \Lambda_s V_\perp^{(s)}.$$  (24)

There are two possible cases for the recursion operators $\Lambda_s$. If $s$ is an exponent then

$$\Lambda_s X = \text{ad}_j^{-1} \left( i \frac{\partial X}{\partial x} + [Q, X] + i \sum_{j=1}^k c_{s,j}^{-1} \mathcal{H}_j^{(s)} \partial_x^{-1} \left( [Q, \mathcal{H}_j^{(s)}], \mathcal{H}_j^{(h-s)} \right) \right),$$

(25)

where $k$ is the multiplicity of the exponent $s$. If $s$ is not an exponent then

$$\Lambda_s X = \text{ad}_j^{-1} \left( i \frac{\partial X}{\partial x} + [Q, X] \right).$$

(26)

The hierarchy of soliton equations is given by

$$\frac{\partial Q}{\partial t} = \frac{\partial}{\partial x} \left( \Lambda_2 \ldots \Lambda_{n-1} V^{(n-1)} \right)$$

$$= \frac{\partial}{\partial x} \left( \Lambda_2 \ldots \Lambda_{n-1} \text{ad}_j^{-1} [K, Q] \right).$$

(27)

4 Hamiltonian formulation

Every equation in the hierarchy (27) has infinitely many integrals of motion. This is due to the underlying bi-Hamiltonian structure. Every integral of motion can be viewed as a Hamiltonian with a properly chosen Poisson structure. We will use the integral of motion given by [35, 36]

$$I = \int_{-\infty}^{\infty} i c_{5,1} \partial_x^{-1} \left( [Q, \Lambda_0 V^{(0)}], \mathcal{H}_1^{(1)} \right) dx.$$  (28)

8
The Hamiltonian $H$ is proportional to (28). Hamilton’s equations are
\[ \partial_t q_i = \{q_i, H\} \quad (29) \]
with a Poisson bracket given by
\[ \{F, G\} = \int_{\mathbb{R}^2} \omega_{ij}(x,y) \delta F \delta G \delta q_i \delta q_j \, dx \, dy, \quad (30) \]
where we sum over repeating indexes. The Poisson structure tensor is
\[ \omega_{ij}(x,y) = \frac{1}{2} \delta_{ij} (\partial_x \delta(x-y) - \partial_y \delta(x-y)). \quad (31) \]
In this case (29) reduces to
\[ \partial_t q_i = \partial_{q_i} \frac{\delta H}{\delta q_i}. \quad (32) \]

5 The one-parameter family of mKdV equations

The first non-trivial member of the hierarchy is a set of mKdV equations which is obtained by (27) and setting $n = 3$. Here, for the sake of completeness, we will derive explicitly the potential of the $M$ operator, which in our particular case is a cubic polynomial in $\lambda$.

As we mentioned above, the algebra $D_4$ is the only simple Lie algebra which has 3 as a double exponent. This means that the element $K$ in (14) involves two arbitrary parameters:
\[ K = \frac{1}{2} a \mathcal{H}_1^{(3)} + \frac{1}{6} b \mathcal{H}_4^{(3)}. \quad (33) \]
The elements $V^{(k)}$ are given as a linear combination of the basis elements in $g^{(k)}$ with some coefficients $v_i^{(k)}$.

The coefficients of $V^{(2)}$ are obtained by solving the first equation from (24)
\[ v_1^{(2)} = 2 \omega a q_1, \\
    v_2^{(2)} = 0, \\
    v_3^{(2)} = -\omega(a + b) q_3, \\
    v_4^{(2)} = -\omega(a - b) q_4. \quad (34) \]
From the second equation of (24), by setting \( s = 2 \), for \( V^{(1)} \) we have

\[
\begin{align*}
\nu_1^{(1)} &= -2a(\omega + 1)\frac{\sqrt{3}}{3} (\partial_x q_1 - \sqrt{3} q_4 q_3 + \sqrt{3} q_2 q_1), \\
\nu_2^{(1)} &= 2aq_1^2 - (a + b)q_3^2 - (a - b)q_4^2, \\
\nu_3^{(1)} &= (a + b)(\omega + 1)\frac{\sqrt{3}}{3} (\partial_x q_3 - \sqrt{3} q_1 q_4 - \sqrt{3} q_2 q_3), \\
\nu_4^{(1)} &= (a - b)(\omega + 1)\frac{\sqrt{3}}{3} (\partial_x q_4 - \sqrt{3} q_1 q_3 - \sqrt{3} q_2 q_4), \\
\nu_5^{(1)} &= aq_1^2 - \frac{1}{2}(a + b)q_3^2 - \frac{1}{2}(a - b)q_4^2.
\end{align*}
\]

(35)

Note that \( \nu_5^{(1)} \) can formally be interpreted as "particle density" and

\[
D = \int_{-\infty}^{\infty} \left( aq_1^2 - \frac{1}{2}(a + b)q_3^2 - \frac{1}{2}(a - b)q_4^2 \right) \, dx
\]

(36)

is an integral of motion.

Using (24) and setting \( s = 1 \), for \( V^{(0)} \) we get

\[
\begin{align*}
\nu_1^{(0)} &= 2a(\partial_x^2 q_1 - \sqrt{3} q_1 \partial_x q_2) - \sqrt{3} ((3a + b)q_4 \partial_x q_3 + (3a - b)q_3 \partial_x q_4) \\
&\quad - 3q_1(2aq_2^2 - (a - b)q_3^2 - (a + b)q_4^2), \\
\nu_2^{(0)} &= \sqrt{3}a\partial_x q_1^2 - \frac{\sqrt{3}}{2}(a + b)\partial_x q_3^2 - \frac{\sqrt{3}}{2}(a - b)\partial_x q_4^2 \\
&\quad - 3q_2 \left( 2aq_1^2 - (a + b)q_3^2 - (a - b)q_4^2 \right), \\
\nu_3^{(0)} &= -(a + b)(\partial_x^2 q_3 - \sqrt{3} q_3 \partial_x q_2) + \sqrt{3} ((3a + b)q_4 \partial_x q_1 + 2bq_1 \partial_x q_4) \\
&\quad - 3q_3 \left( 2aq_1^2 - (a - b)q_2^2 - (a + b)q_4^2 \right), \\
\nu_4^{(0)} &= -(a - b)(\partial_x^2 q_4 - \sqrt{3} q_4 \partial_x q_2) + \sqrt{3} ((3a - b)q_3 \partial_x q_1 - 2bq_1 \partial_x q_3) \\
&\quad - 3q_4 \left( 2aq_3^2 - (a - b)q_2^2 - (a + b)q_1^2 \right).
\end{align*}
\]

(37)
Finally, the equations obtained from \([27]\), are
\[
\partial_t q_1 = \partial_x \left( 2a(\partial_x^2 q_1 - \sqrt{3}q_1 \partial_x q_2) - \sqrt{3} ((3a + b)q_4 \partial_x q_3 + (3a - b)q_3 \partial_x q_4) \\
- 3q_1 (2aq_2^2 - (a - b)q_3^2 - (a + b)q_4^2) \right),
\]
\[
\partial_t q_2 = \partial_x \left( \sqrt{3}a \partial_x q_1^2 - \frac{\sqrt{3}}{2} (a + b) \partial_x q_3^2 - \frac{\sqrt{3}}{2} (a - b) \partial_x q_4^2 \right) \\
- 3q_2 (2aq_1^2 - (a + b)q_3^2 - (a - b)q_4^2),
\]
\[
\partial_t q_3 = \partial_x \left( - (a + b)(\partial_x^2 q_4 - \sqrt{3}q_4 \partial_x q_2) + \sqrt{3} ((3a + b)q_4 \partial_x q_1 + 2bq_1 \partial_x q_4) \\
- 3q_3 (2aq_1^2 - (a + b)q_2^2 - (a - b)q_4^2) \right),
\]
\[
\partial_t q_4 = \partial_x \left( - (a - b)(\partial_x^2 q_4 - \sqrt{3}q_4 \partial_x q_2) + \sqrt{3} ((3a - b)q_3 \partial_x q_1 - 2bq_1 \partial_x q_3) \\
- 3q_4 (2aq_3^2 - (a - b)q_2^2 - (a + b)q_1^2) \right).
\]
The density of the Hamiltonian given by \([28]\) is
\[
\mathcal{H} = \frac{1}{3} \left( 2aq_1 \partial_x^2 q_1 - (a + b)q_3 \partial_x^2 q_3 - (a - b)q_4 \partial_x^2 q_4 \right) \\
- \frac{1}{6} \left( 2a(\partial_x q_1)^2 - (a + b)(\partial_x q_3)^2 - (a - b)(\partial_x q_4)^2 \right) \\
+ 2a \sqrt{3} \left( (q_4 q_3 + \frac{1}{3} q_2 q_1) \partial_x q_1 - \frac{1}{3} q_1^2 \partial_x q_2 \right) \\
- (a + b) \sqrt{3} \left( (q_4 q_1 - \frac{1}{3} q_2 q_3) \partial_x q_3 - \frac{1}{3} q_3^2 \partial_x q_2 \right) \\
- (a - b) \sqrt{3} \left( (q_3 q_1 - \frac{1}{3} q_2 q_4) \partial_x q_4 - \frac{1}{3} q_1^2 \partial_x q_2 \right) \\
- \frac{3}{2} \left( 2(q_1^2 q_2^2 + q_4^2 q_2) - (a + b)(q_1^2 q_4^2 + q_2^2 q_3^2) - (a - b)(q_1^2 q_3^2 + q_2^2 q_4^2) \right)
\]
with Hamilton’s equations given by \([32]\).

As we demonstrated above, the set of mKdV equations, as well as their Hamiltonian \([38]\) involve two arbitrary parameters \(a\) and \(b\). However, one of these parameters, say \(a\), can always be put to 1 by re-scaling \(t\) to \(t/a\). That is why we have effectively a one-parameter family of mKdV equations.

Note that for any other simple Lie algebra 3 is a single-valued exponent. As a result \(K\) may involve only one parameter, which can always be re-scaled to 1. Therefore the mKdV
equations related to the other simple Lie algebras do not allow arbitrary parameters as their coefficients.

6 Spectral properties of \( L \) and fundamental analytic solutions

Let us analyze the spectral properties of \( L \) and outline the construction of its FAS. A basic tool in this analysis are the Jost solutions

\[
\lim_{x \to -\infty} \phi_-(x, t, \lambda)e^{iJ\lambda x} = \mathbb{I}, \quad \lim_{x \to \infty} \phi_+(x, t, \lambda)e^{iJ\lambda x} = \mathbb{I}.
\]  

(39)

Then the scattering matrix is introduced by

\[
T(\lambda, t) = \hat{\phi}_+(x, t, \lambda)\phi_-(x, t, \lambda),
\]

(40)

where by ”hat” we denote matrix inverse. Formally the Jost solutions must satisfy Volterra type integral equations. If we introduce

\[
\xi_\pm(x, t, \lambda) = \phi_\pm(x, t, \lambda)e^{i\lambda Jx},
\]

(41)

then \( \xi_\pm(x, t, \lambda) \) must satisfy

\[
\begin{align*}
\xi_+(x, t, \lambda) &= \mathbb{I} + i \int_{-\infty}^{x} dy \ e^{-i\lambda J(x-y)}Q(y, t)\xi_+(y, t, \lambda)e^{i\lambda J(x-y)}, \\
\xi_-(x, t, \lambda) &= \mathbb{I} + i \int_{-\infty}^{x} dy \ e^{-i\lambda J(x-y)}Q(y, t)\xi_-(y, t, \lambda)e^{i\lambda J(x-y)}.
\end{align*}
\]

(42)

However, in our case \( J \) is complex-valued, and a simple analysis shows that the Jost solutions exist only for potentials on compact support. Beals and Coifman showed that any potential can be approximated to arbitrary accuracy with a potential on a finite support [7]. This result was later generalized to potential with coefficients from any finite-dimensional simple Lie algebra [34]. Reformulating the general results of [34, 36], for the particular choice of the algebra \( D_4 \simeq so(8) \) we find that

1. The continuous spectrum of \( L \) fills up the set of rays \( l_\nu, \nu = 0, \ldots 11 \) in the complex \( \lambda \)-plane for which

\[
\text{Im} \lambda \alpha(J) = 0,
\]

(43)

where \( \alpha \) is any root of \( D_4 \) and \( J \) is given by (17), see Figure 1. These rays are defined by

\[
l_\nu = \arg \lambda = \frac{\pi \nu}{6}, \quad \nu = 0, \ldots 11.
\]

(44)
Figure 1: The continuous spectrum of $L$ with $\mathbb{Z}_6$-symmetry fills up the rays $l_\nu$, $\nu = 0, \ldots, 11$; $\Omega_\nu$ are the analyticity regions of the FAS $\xi_\nu(x, t, \lambda)$.

With each ray one can relate a subalgebra $\mathfrak{g}_\nu$ with root systems $\delta_\nu$ whose roots satisfy
\[
\delta_\nu \equiv \{ \alpha \in \delta_\nu \ \text{iff} \ \text{Im} \lambda \alpha(J) = 0 \ \forall \lambda \in l_\nu \}. \tag{45}
\]

More specifically we have
\[
\begin{align*}
\delta_0 & \equiv \{ \pm (e_2 + e_3), \pm (e_1 - e_4), \pm (e_1 + e_4) \}, & \delta_1 & \equiv \{ \pm (e_1 + e_3) \}, \\
\delta_2 & \equiv \{ \pm (e_1 - e_2), \pm (e_3 - e_4), \pm (e_3 + e_4) \}, & \delta_3 & \equiv \{ \pm (e_2 - e_3) \}, \\
\delta_4 & \equiv \{ \pm (e_1 - e_3), \pm (e_2 - e_4), \pm (e_2 + e_4) \}, & \delta_5 & \equiv \{ \pm (e_1 + e_2) \}\tag{46}
\end{align*}
\]

and $\delta_{\nu+6} \equiv \delta_\nu$, $\nu = 0, \ldots, 5$. 

13
Table 1: The signs $s_{jk} = s_{9-k,9-j}$ in (48). We have listed only the values of $s_{jk}$ for $j < k$ because $s_{k,j} = -s_{jk}$. Also the signs for $\Omega_{\nu+6}$ are opposite to the signs for $\Omega_{\nu}$, $\nu = 0, \ldots, 5$.

2. The regions of analyticity of the FAS $\xi_{\nu}(x, t, \lambda)$ are the sectors

$$\Omega_{\nu} \equiv \left\{ \frac{\pi \nu}{6} \leq \arg \lambda \leq \frac{\pi (\nu + 1)}{6} \right\}. \quad (47)$$

They can be introduced as the solutions of the set of integral equations

$$\xi_{\nu,ij}(x, t, \lambda) = \delta_{ij} + i \int_{s_{ij}\infty}^{x} dy e^{-i\lambda(J_i - J_j)(x-y)}(Q(y, t)\xi_{\nu}(y, t, \lambda))_{ij}, \quad (48)$$

where $\lambda \in \Omega_{\nu}$ and $s_{ij}$ take the values $\pm 1$, which are specific for each of the sectors $\Omega_{\nu}$, see Table 1.

3. In each of the sectors $\Omega_{\nu}$ we introduce an ordering of the roots calling the root $\alpha$ $\nu$-positive (resp. $\nu$-negative) if $\text{Im} \lambda \alpha(J) > 0$ (resp. $\text{Im} \lambda \alpha(J) < 0$) for $\lambda \in \Omega_{\nu}$. Thus the sets of positive roots of the subalgebras $g_{\nu}$ are

$$\delta_0^+ \equiv \{e_2 + e_3, e_1 - e_4, e_1 + e_4\}, \quad \delta_1^+ \equiv \{e_1 + e_3\},$$
$$\delta_2^+ \equiv \{e_1 - e_2, e_3 - e_4, e_3 + e_4\}, \quad \delta_3^+ \equiv \{e_2 - e_3\},$$
$$\delta_4^+ \equiv \{e_1 - e_3, e_2 - e_4, e_2 + e_4\}, \quad \delta_5^+ \equiv \{e_1 + e_2\}. \quad (49)$$

Note that the root systems $\delta_{1,3,5}$ are isomorphic to the root system of $sl(2)$, while each of the root systems $\delta_{0,2,4}$ is isomorphic to the direct sum of three $sl(2)$ algebras. Indeed, it is enough to check that all the roots in $\delta_{0,2,4}$ are mutually orthogonal.

4. As set of scattering data we introduce the limits of the FAS along both sides of all rays $l_{\nu}e^{\pm i\theta}$:

$$\lim_{x \to -\infty} e^{-i\lambda J(x, t, \lambda)}e^{i\lambda J} = S_{\nu}^+(t, \lambda),$$
$$\lim_{x \to \infty} e^{-i\lambda J(x, t, \lambda)}e^{i\lambda J} = T_{\nu}^-(t, \lambda)D_{\nu}^+(\lambda), \quad \forall \lambda \in l_{\nu}e^{\pm i\theta}. \quad (50)$$

14
\[ \lim_{x \to -\infty} e^{iJx} \xi_{\nu}(x, t, \lambda) e^{iJx} = S_{\nu+1}(t, \lambda), \]
\[ \lim_{x \to -\infty} e^{-iJx} \xi_{\nu}(x, t, \lambda) e^{iJx} = T_{\nu+1}(t, \lambda) D_{\nu+1}^{-}(\lambda), \quad \forall \lambda \in l_{\nu+1} e^{-i\theta}, \] (51)

where \( S_{\nu}^{\pm}, T_{\nu}^{\pm} \) and \( D_{\nu}^{\pm} \) are elements of the subgroup \( G_{\nu} \) of the form

\[ S_{\nu}^{\pm}(t, \lambda) = \exp \left( \sum_{\alpha \in \delta_{\nu}^{\pm}} s_{\alpha, \nu}^{\pm}(t, \lambda) E_{\pm \alpha} \right), \]
\[ T_{\nu}^{\pm}(t, \lambda) = \exp \left( \sum_{\alpha \in \delta_{\nu}^{\pm}} \tau_{\alpha, \nu}^{\pm}(t, \lambda) E_{\pm \alpha} \right), \] (52)
\[ D_{\nu}^{\pm}(\lambda) = \exp \left( \sum_{\alpha \in \delta_{\nu}^{\pm}} d_{\alpha, \nu}^{\pm}(\lambda) H_{\alpha} \right) \]
satisfying

\[ T_{\nu}^{\pm} D_{\nu}^{-} \hat{S}_{\nu}^{\pm} = T_{\nu}^{\pm} D_{\nu}^{+} \hat{S}_{\nu}^{-} = T_{\nu}(\lambda, t), \quad \lambda \in l_{\nu}. \] (53)

For potentials on compact support \( T_{\nu}(\lambda, t) \) is the scattering matrix, which for \( \lambda \in l_{\nu} \) is also taking values in the subgroup \( G_{\nu} \). Then (53) is the Gauss decomposition of \( T_{\nu}(\lambda, t) \). We only need to add, that the functions \( D_{\nu}^{\pm} \) and \( D_{\nu+1}^{-} \) are analytic in the sector \( \Omega_{\nu} \).

5. The FAS \( \xi_{\nu}(x, t, \lambda) \) satisfy a RHP:

\[ \xi_{\nu+1}(x, t, \lambda) = \xi_{\nu}(x, \lambda) G_{\nu}(x, \lambda), \quad G_{\nu}(x, \lambda) = e^{-iJx} \hat{S}_{\nu+1}^{-} S_{\nu+1}^{+}(\lambda) e^{iJx}, \] (54)

which allows canonical normalization:

\[ \lim_{\lambda \to \infty} \xi_{\nu}(x, \lambda) = I. \] (55)

From Zakharov-Shabat theorem [68] the solution of the RHP (54) with canonical normalization is a FAS of the system

\[ i \frac{\partial \xi_{\nu}}{\partial x} + Q(x) \xi_{\nu}(x, \lambda) - \lambda [J, \xi_{\nu}(x, \lambda)] = 0, \] (56)

which means that \( \chi_{\nu}(x, \lambda) = \xi_{\nu}(x, \lambda) e^{-iJx} \) are FAS of the Lax operator \( L \).

A basic step in applying the ISM is the analysis of the mapping between the space of admissible potentials \( \mathcal{M} \) and the space of scattering data. In view of Zakharov-Shabat theorem it is natural to expect that the minimal sets of scattering data are determined by the set of \( S_{\nu}^{\pm}(t, \lambda) \). In fact we can prove the following lemma
Thus from (53) we obtain that
\[ g_\nu, j \] is the corresponding fundamental representation of \( \nu \) evaluated with the ordering in \( \Omega \).

The functions \( \tau \) along the rays \( l \) (53) by
\[ \langle \nu, \alpha \rangle \]
end we make use of the analyticity properties of \( D \) sets of scattering data determining uniquely both the scattering matrix \( T(t, \lambda) \) and the potential \( Q(x, t) \).

First we will prove that each of the sets \( T_i, i = 1, 2 \) determines uniquely the full set of scattering data. Assume we are given the set \( T_1 \). Looking at the first equation from (52), \( T_1 \) uniquely determines the matrices \( S_0^\pm(\lambda) \) for \( \lambda \in l_0 e^{\pm i0} \) and \( S_1^\pm(\lambda) \) for \( \lambda \in l_1 e^{\pm i0} \). Using the \( \mathbb{Z}_6 \) reduction condition we can determine the matrices \( S_2^\pm(\lambda) \) for \( \lambda \in l_{\nu} e^{\pm i0} \) along all other rays by the relations
\[
\begin{align*}
S_2^+(\lambda) &= c^{\nu} S_0^+(\omega^- \nu, \lambda) c^{-\nu}, & \lambda &\in l_\nu e^{\pm i0}, \\
S_{2\nu+1}^-(\lambda) &= c^{\nu} S_1^-(\omega^- \nu, \lambda) c^{-\nu}, & \lambda &\in l_{\nu+1} e^{\pm i0}.
\end{align*}
\]

The next step is to demonstrate that by knowing all \( S_\nu^\pm(\lambda) \) we can recover \( D_\nu^\pm(\lambda) \). To this end we make use of the analyticity properties of \( D_\nu^\pm(\lambda) \) and (53). Indeed, let us sandwich \( \langle \nu, \alpha \rangle \) by \( \langle \omega_\nu^+, \ldots, \omega_\nu^- \rangle \), where \( \omega_\nu^+ \) is the \( j \)-th fundamental weight of the subalgebra \( g_\nu \) evaluated with the ordering in \( \Omega_\nu \). Obviously \( \omega_\nu^+ \) are the highest weight vectors in the corresponding fundamental representation of \( g_\nu \). Analogously \( \omega_\nu^- \) are the lowest weight vectors in the same fundamental representation of \( g_\nu \). We also need the following properties of the weight vectors \( \langle \omega_\nu^\pm, | \omega_\nu^\pm, \rangle \) and the factors \( S_\nu^\pm(\lambda), T_\nu^\pm(\lambda), D_\nu^\pm(\lambda) \):
\[
\begin{align*}
\langle \omega_\nu^+, S_\nu^+(\lambda)| \omega_\nu^+ \rangle &= \langle \omega_\nu^+, T_\nu^-(\lambda)| \omega_\nu^+ \rangle = \langle \omega_\nu^-, T_\nu^+(\lambda)| \omega_\nu^- \rangle = \langle \omega_\nu^-, S_\nu^-(\lambda)| \omega_\nu^- \rangle,
\end{align*}
\]
and
\[
\begin{align*}
\langle \omega_\nu^+, D_\nu^+(\lambda)| \omega_\nu^- \rangle &= e^{d_{\nu, \alpha}}, & \langle \omega_\nu^-, D_\nu^- (\lambda)| \omega_\nu^- \rangle &= e^{-d_{\nu, \alpha}}.
\end{align*}
\]

Thus from (53) we obtain that
\[
\begin{align*}
d_{\nu, \alpha} &= \ln \langle \omega_\nu^+, S_\nu^+(\lambda)| \omega_\nu^- \rangle - \ln \langle \omega_\nu^-, T_\nu^+(\lambda)| \omega_\nu^- \rangle
\end{align*}
\]

The functions \( d_{\nu, \alpha} \) can be recovered uniquely from their analyticity properties and from the jumps (61) along the rays \( t_{\nu} \), which in turn allows us to recover the factors \( D_\nu^\pm(\lambda) \).
As a result, we can rewrite (53) in the form
\[
D^- \hat{S}_\nu^+ \hat{D}_\nu^+ = \hat{T}_\nu^+(\lambda, t)T^-_\nu, \quad \lambda \in l_\nu.
\]
(62)
Now the factors \(T_\nu^\pm(\lambda)\) are recovered as the unique Gauss factors of the right hand side of (62).

The proof that \(T_2\) determines uniquely all the scattering data is analogous.

Finally, the corresponding potential is reconstructed from \([59, 31, 34]\)
\[
Q(x, t) = \lim_{\lambda \to \infty} \lambda \left( J - \xi_\nu(x, t, \lambda) \hat{J}_\nu(x, t, \lambda) \right),
\]
(63)
where \(\xi_\nu(x, t, \lambda)\) is the unique regular solution of the RHP (54).

\[\square\]

### 6.1 Time dependence of the scattering data

The Lax representation ensures that \(L\) and \(M\) allow the same set of fundamental solutions. As such we shall choose the FAS. A bit more generally, we can assume that
\[
L\chi_\nu(x, t, \lambda) = 0, \quad M\chi_\nu(x, t, \lambda) = \chi_\nu(x, t, \lambda) \Gamma(\lambda) = 0,
\]
(64)
where \(\phi_+(x, t, \lambda) = \xi_+(x, t, \lambda)e^{i\lambda Jx}\) and \(\Gamma(\lambda)\) is a constant matrix. We shall fix \(\Gamma(\lambda)\) in such a way, that the definition of the Jost solutions are \(t\)-independent.

Let \(\lambda \in l_\nu e^{i0}\) and let us calculate the limit
\[
\lim_{x \to -\infty} \left( M\chi_\nu(x, t, \lambda) \right) e^{i\lambda Jx}
\]
\[
= \lim_{x \to -\infty} \left[ \left( i \frac{\partial}{\partial t} + \sum_{p=0}^{m-1} \lambda^p V_p - \lambda^m K \right) \chi_\nu(x, t, \lambda) - \chi_\nu(x, t, \lambda) \Gamma(\lambda) \right] e^{i\lambda Jx}
\]
(65)
\[
= i \frac{\partial S_\nu^+}{\partial t} - \lambda^m K S_\nu^+(t, \lambda) - \lim_{x \to -\infty} S_\nu^+(t, \lambda)e^{-i\lambda Jx} \Gamma(\lambda)e^{i\lambda Jx}, \quad \lambda \in l_\nu e^{+i0},
\]
where we took into account that all \(V_k(x, t)\) vanish for \(x \to \pm \infty\). Thus we obtain that
\[
i \frac{\partial S_\nu^+}{\partial t} - \lambda^m K S_\nu^+(t, \lambda) - \lim_{x \to -\infty} e^{-i\lambda Jx} S_\nu^+(t, \lambda) \Gamma(\lambda)e^{i\lambda Jx} = 0.
\]
(66)
First we consider the diagonal part of the above equation taking into account that from (52) it follows that all diagonal elements of \(S_\nu^+(t, \lambda)\) are equal to 1. This immediately gives
\[
\lambda^m K + \lim_{x \to -\infty} e^{-i\lambda Jx} \Gamma(\lambda)e^{i\lambda Jx} = \lambda^m K + \Gamma(\lambda) = 0,
\]
(67)
\[ i \frac{\partial S^+_\nu}{\partial t} - \lambda^m [K, S^+_\nu(t, \lambda)] = 0, \quad \lambda \in l_\nu e^{\pm i0}. \]  

Next we calculate similar limits for \( x \to \infty \):

\[
\lim_{x \to \infty} \left( M \chi_{\nu}(x, t, \lambda) \right) e^{i\lambda J x} = \lim_{x \to \infty} \left[ \left( i \frac{\partial}{\partial t} + \sum_{p=0}^{m-1} \lambda^p V_p - \lambda^m K \right) \chi_{\nu}(x, t, \lambda) - \chi_{\nu}(x, t, \lambda) \Gamma(\lambda) \right] e^{i\lambda J x} \]  

\[ = i \frac{\partial T^-_\nu D^+_\nu}{\partial t} - \lambda^m [K, T^-_\nu(t, \lambda) D^+_\nu(\lambda)] = 0. \]  

Again we consider first the diagonal part of (69) and remember that all diagonal elements of the lower triangular matrix \( T^-_\nu(t, \lambda) \) are equal to 1. We obtain that

\[ i \frac{\partial D^+_\nu}{\partial t} = 0, \]  

i.e. the matrix elements of \( D^+_\nu(\lambda) \) are generating functionals of the integrals of motion of the NLEE. Finally, the lower triangular part of (69) gives

\[ i \frac{\partial T^-_\nu}{\partial t} - \lambda^m [K, T^-_\nu(t, \lambda)] = 0, \quad \lambda \in l_\nu e^{\pm i0}. \]  

Analogously we can set \( \lambda \in l_\nu e^{-i0} \) and evaluate the limits for \( x \to \pm \infty \). Therefore, if \( Q(x, t) \) satisfies the corresponding equations then the time evolution of the scattering data will be given by

\[
i \frac{\partial S^+_{\alpha,\nu}}{\partial t} - \lambda^m [K, S^+_{\alpha,\nu}(t, \lambda)] = 0, \quad i \frac{\partial T^-_{\alpha,\nu}}{\partial t} - \lambda^m [K, T^-_{\alpha,\nu}(t, \lambda)] = 0, \quad \lambda \in l_\nu e^{\pm i0}, \]

\[
i \frac{\partial S^-_{\alpha,\nu}}{\partial t} - \lambda^m [K, S^-_{\alpha,\nu}(t, \lambda)] = 0, \quad i \frac{\partial T^+_{\alpha,\nu}}{\partial t} - \lambda^m [K, T^+_{\alpha,\nu}(t, \lambda)] = 0, \quad \lambda \in l_\nu e^{-i0}. \]

and the diagonal factors \( D^\pm_{\nu}(\lambda) \) are \( t \)-independent. In other words \( d^+_{\alpha,\nu}(\lambda) \) are also \( t \)-independent and are more convenient as generating functionals of conservation laws. The reason for this is, that if we consider the expansion of, say \( d^+_{\alpha,\nu}(\lambda) \) over the inverse powers of \( \lambda \), that is

\[ d^+_{\alpha,\nu}(\lambda) = \sum_{p=1}^{\infty} C^{(p)}_{\alpha,\nu} \lambda^{-p}, \]

then their densities will be local, i.e. they will be expressed in terms of the coefficients of \( Q(x, t) \) and their \( x \)-derivatives, see [55, 35].
The solution of the equations (72) is given by

\[ S_{\nu,kj}(t, \lambda) = e^{i\lambda m(K_k-K_j)t} S_{\nu,ij}^\pm (\lambda, 0), \quad T_{\nu,kj}(t, \lambda) = e^{i\lambda m(K_k-K_j)t} T_{\nu,ij}^\pm (\lambda, 0). \] (74)

Thus \( S_{\nu}^\pm (\lambda, 0) \) (resp. \( T_{\nu}^\pm (\lambda, 0) \)) for \( \nu = 0,1 \) can be viewed as the Cauchy data for the initial conditions. Therefore solving the corresponding equations reduces to solving the direct and the inverse scattering problem for the Lax operator \( L \), see [35, 55].

7 Discussion and conclusions

In this paper we investigated some aspects of the deep relation between integrable equations and infinite-dimensional Lie algebras. More concretely, we studied the hierarchy corresponding in the scheme of Drinfeld and Sokolov to the untwisted affine Kac-Moody Lie algebra \( D^{(1)}_4 \).

The NLEE related to \( D^{(1)}_4 \) deserve special attention due to the unique properties of \( D_4^{(1)} \). This is the only simple Lie algebra whose Dynkin diagram has an \( S_3 \) symmetry and which has 3 as a double-valued exponent. We formally constructed the hierarchy of soliton equations using the recursion operators. Thus the general theory of the recursion operators with deep reductions [35, 36] has been adapted to the specific case of \( D_4 \).

Special attention is paid to the first nontrivial member of the hierarchy which is an one-parameter family of mKdV equations. Note that this family of mKdV equations is unique! Among the simple Lie algebras only \( D^{(1)}_2 \) allow double-valued exponents equal to \( 2r-1 \). Thus with each such algebra one can relate an one-parameter family of mKdV-like equations. These will be systems of \( 2r \) evolution equations for \( 2r \) independent functions whose leading \( x \)-derivative terms will be of order \( 2r - 1 \). In particular, with \( D^{(1)}_6 \) one could relate a system of \( 6 \) evolution equations for \( 6 \) independent functions whose leading \( x \)-derivative will be of order \( 5 \). All these equations have an infinite number of integrals of motion and a natural Hamiltonian formulation. The properties of their Hamiltonian hierarchies will analyzed elsewhere.

We also outlined the spectral properties of the Lax operator \( L \) which has an in-built \( \mathbb{Z}_6 \)-reduction of Mikhailov type [55]. In particular, we constructed the FAS of the system and the associated RHP. We also formulated two minimal sets of scattering data of \( L \) from which one can recover uniquely both the scattering matrix \( T(\lambda, t) \) and the potential \( Q(x, t) \) of \( L \).

A natural extension of these results is to study the soliton equations associated with the twisted affine Kac-Moody algebras. The corresponding integrable hierarchies related to the twisted affine Kac-Moody algebras \( A^{(2)}_{2r} \), \( A^{(2)}_{2r-1} \) and \( D^{(2)}_4 \) are under investigations and have been presented elsewhere [41, 42, 43].

Another continuation in this direction involves constructing the soliton solutions of the obtained integrable hierarchies using, for example, the dressing method [70, 55] and analyzing their properties.
Acknowledgements

We are grateful to Laslo Fehér for the very useful discussions. The work is partially supported by the ICTP - SEENET-MTP project PRJ-09. One of us (VSG) is grateful to professors A.S. Sorin, A. V. Mikhailov and V. V. Sokolov for useful discussions during his visit to JINR, Dubna, Russia under project 01-3-1116-2014/2018.

Appendix

A The simple Lie algebra $D_4$

Let $\mathfrak{g}$ be a simple Lie algebra. A Cartan-Weyl basis in $\mathfrak{g}$ is a system of generators $H_i, E_{\alpha_i}, E_{-\alpha_i}, 1 \leq i \leq r$ such that

$$
[H_i, H_j] = 0, \\
[E_{\alpha_i}, E_{-\alpha_j}] = \delta_{ij} H_i, \\
[H_i, E_{\alpha_j}] = C_{ij} H_i, \\
[H_i, E_{-\alpha_j}] = -C_{ij} H_i.
$$

The matrix $(C_{ij})$ is non-degenerate and is called the Cartan matrix of $\mathfrak{g}$. The number $r$ is called the rank of the algebra. The generators $H_i$ form an Abelian subalgebra called the Cartan subalgebra. Every simple Lie algebra is uniquely determined by its Cartan matrix and can also be represented by a Dynkin diagram [11].

The simple Lie algebra $D_4 \equiv \mathfrak{so}(8)$ is usually represented by a $8 \times 8$ antisymmetric matrices. In this realization the Cartan subalgebra is not diagonal, so we will use a realization for which every $X \in D_4$ satisfies

$$
SX + (SX)^T = 0,
$$

where the matrix $S$ is given by

$$
S = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}.
$$

This way the Cartan subalgebra is given by diagonal matrices.
The Cartan-Weyl basis of $D_4$ is given by

\[ H_i = e_{ii} - e_{9-i,9-i}, \quad 1 \leq i \leq 4, \]
\[ E_{\alpha_j} = e_{j,j+1} + e_{8-j,9-j}, \quad 1 \leq j \leq 3, \]  
\[ E_{\alpha_4} = e_{3,5} + e_{4,6}, \quad E_{-\alpha_j} = (E_{\alpha_j})^T, \]  

(78)

where by $e_{ij}$ we denote a matrix that has a one at the $i$-th row and $j$-th column and is zero everywhere else.

B Dihedral realization of the Coxeter automorphism

Let $e_i$ be an orthonormal basis in the root space of $D_4$ and let the simple roots be of the form

\[ \alpha_1 = e_1 - e_2, \quad \alpha_2 = e_2 - e_3, \quad \alpha_3 = e_3 - e_4, \quad \alpha_4 = e_3 + e_4. \]  

(79)

In the dihedral realization the Coxeter automorphism is an element of the Weyl group of the form

\[ C = w_1 w_2 \]  

(80)

with

\[ w_1 = \prod_{\alpha \in A_1} S_\alpha, \quad w_2 = \prod_{\beta \in A_2} S_\beta, \]  

(81)

where $A_1$ and $A_2$ are subsets of the simple roots $A = \{\alpha_1, \alpha_2, \alpha_3, \alpha_4\}$, such that

\[ A_1 = \{\alpha_1, \alpha_3, \alpha_4\}, \quad A_2 = \{\alpha_2\}. \]  

(82)

Here $S_\alpha$ is the reflection with respect to the simple root $\alpha$. For the Coxeter element we get

\[ C = S_{\alpha_1} S_{\alpha_3} S_{\alpha_4} S_{\alpha_2}. \]  

(83)

The action of $C$ on the basis vectors is

\[ C : e_1 \to e_2 \to -e_3 \to -e_1 \to -e_2 \to e_3, \]
\[ C : e_4 \to -e_4. \]  

(84)

It is obvious that $C$ divides the root space into orbits. It is not difficult to check that each orbit contains only one simple root and the orbits are not intersecting. When constructing the basis we will select one element from each orbit, namely, the simple roots $\alpha_i$.

In the algebra $C$ is realized as an inner automorphism, i.e. a similarity transformation

\[ C(X) = cXc^{-1}, \quad X \in D_4^{(1)}, \]  

(85)
where \( c \) belongs to the corresponding group. In order to find \( c \) we will look at the typical representation of \( D_4 \). From (84) we can infer that

\[
\begin{pmatrix}
e_1 \\
e_2 \\
e_3 \\
e_4 \\
-e_4 \\
-e_3 \\
-e_2 \\
-e_1
\end{pmatrix}
= \begin{pmatrix}
a_1e_2 \\
a_2(-e_3) \\
a_3e_1 \\
a_4(-e_4) \\
a_5(e_4) \\
a_6(-e_1) \\
a_7(-e_3) \\
a_8(-e_2)
\end{pmatrix},
\]

(86)

for some coefficients \( a_i \). The following must also be true

\[
cSc^T S = I, \quad c^6 = \pm I,
\]

(87)

i.e. the matrix \( c \) must be a group element and it must give the Coxeter automorphism (the Coxeter number for \( D_4^{(1)} \) is 6). From (86) and (87) we find that one possible choice of \( c \) is given by

\[
c = \begin{pmatrix}
0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0
\end{pmatrix}.
\]

(88)

C Basis in \( D_4^{(1)} \)

Every element of \( D_4^{(1)} \) is of the form

\[
X = \sum_{k=n}^{m} X^{(k)} \lambda^k, \quad n, m \in \mathbb{Z},
\]

(89)

where \( X^{(k)} \in \mathfrak{g}^{(k \mod 6)} \). For the elements \( X^{(k)} \) we have

\[
X^{(k)} = \sum_{i=1}^{4} x_i \mathcal{E}_i^{(k)} + \sum_{j=1}^{s} x_{4+s} \mathcal{H}_s^{(k)},
\]

(90)
where $s$ is the multiplicity of the exponent $k$. The explicit form of $X^{(k)}$ is

$$X^{(0)} = \begin{pmatrix}
0 & x_1 & x_1 & -x_4 & -x_3 & x_2 & -x_2 & 0 \\
-x_1 & 0 & x_2 & -x_3 & -x_4 & x_1 & 0 & -x_2 \\
-x_1 & -x_2 & 0 & x_3 & x_4 & 0 & x_1 & -x_2 \\
x_4 & x_3 & -x_3 & 0 & 0 & x_4 & x_4 & -x_3 \\
x_3 & x_4 & -x_4 & 0 & 0 & x_3 & x_3 & -x_4 \\
x_2 & -x_1 & 0 & -x_4 & -x_3 & 0 & x_2 & -x_1 \\
x_2 & 0 & -x_1 & -x_4 & -x_3 & -x_2 & 0 & x_1 \\
0 & x_2 & x_2 & x_3 & x_4 & x_1 & -x_1 & 0
\end{pmatrix},$$

$$X^{(1)} = \begin{pmatrix}
2x_5 & x_1 & \omega^2x_1 & 0 & -x_4 & -x_3 & -x_2 & x_2 \\
x_1 & 2\omega x_5 & x_2 & -x_4 & -x_3 & -x_2 & x_2 & 0 \\
\omega^2x_1 & x_2 & -2\omega x_5 & x_3 & x_4 & 0 & x_1 & \omega x_2 \\
-x_4 & -x_3 & 0 & 0 & x_4 & \omega^2x_4 & -x_3 & x_1 \\
-x_4 & -2\omega x_4 & x_4 & 0 & x_3 & x_3 & -x_4 & x_1 \\
-x_2 & 0 & x_4 & x_3 & 2\omega x_5 & x_2 & -x^2 & x_1 \\
\omega^2x_2 & 0 & \omega x_1 & \omega^2x_4 & \omega^2x_3 & \omega x_2 & -2\omega x_5 & x_1 \\
0 & \omega^2x_2 & \omega x_2 & -x_3 & -x_4 & -\omega^2x_1 & x_1 & -2\omega x_5
\end{pmatrix},$$

$$X^{(2)} = \begin{pmatrix}
0 & x_1 & -x_4 & -x_3 & -x_2 & x_2 & 0 \\
-x_1 & 0 & x_2 & \omega x_3 & \omega x_4 & \omega^2x_1 & 0 & \omega x_2 \\
\omega x_1 & -x_2 & 0 & x_3 & x_4 & 0 & \omega^2x_1 & -\omega x_2 \\
\omega^2x_4 & -x_4 & x_3 & 0 & 0 & x_4 & -x_3 & \omega^2x_4 \\
\omega^2x_3 & -x_4 & -x_4 & 0 & 0 & x_3 & -x_3 & \omega^2x_4 \\
-x_2 & 0 & -x_4 & x_3 & 2\omega x_5 & x_2 & -x^2 & x_1 \\
-x_2 & 0 & -x_1 & x_4 & x_3 & x_2 & 2\omega x_5 & x_1 \\
0 & x_2 & -x_2 & x_3 & x_4 & -x_1 & x_1 & -2\omega x_5
\end{pmatrix},$$

$$X^{(3)} = \begin{pmatrix}
2x_5 & x_1 & x_1 & x_4 & x_3 & x_2 & x_2 & 0 \\
x_1 & -2x_5 & x_2 & -x_3 & -x_4 & -x_1 & 0 & x_2 \\
x_1 & x_2 & -2x_5 & x_3 & x_4 & 0 & -x_1 & -x_2 \\
x_4 & -x_3 & x_3 & 6x_6 & 0 & x_4 & x_4 & x_3 \\
x_3 & -x_4 & x_4 & 0 & -6x_6 & x_3 & x_3 & x_4 \\
x_2 & -x_1 & 0 & x_4 & x_3 & 2\omega x_5 & x_2 & -x_1 \\
x_2 & 0 & -x_1 & x_4 & x_3 & x_2 & 2\omega x_5 & x_1 \\
0 & x_2 & -x_2 & x_3 & x_4 & -x_1 & x_1 & -2\omega x_5
\end{pmatrix},$$

$$X^{(4)} = \begin{pmatrix}
0 & x_1 & \omega^2x_1 & \omega x_4 & \omega x_3 & -x_2 & -\omega^2x_2 & 0 \\
-x_1 & 0 & x_2 & -\omega^2x_3 & -\omega^2x_4 & \omega x_4 & 0 & -\omega^2x_2 \\
-\omega^2x_1 & -x_2 & 0 & x_3 & x_4 & 0 & -\omega x_1 & \omega x_2 \\
-x_2 & \omega^2x_3 & -x_4 & 0 & 0 & x_4 & \omega^2x_4 & \omega x_3 \\
-x_2 & \omega^2x_4 & x_4 & 0 & 0 & x_3 & \omega^2x_3 & \omega x_4 \\
\omega x_2 & \omega x_1 & 0 & -x_4 & -x_3 & 0 & x_2 & -\omega^2x_1 \\
\omega^2x_2 & 0 & \omega x_1 & -\omega^2x_4 & -\omega^2x_3 & -x_2 & 0 & x_1 \\
0 & \omega^2x_2 & -\omega x_2 & -\omega x_3 & -\omega x_4 & \omega^2x_1 & -x_1 & 0
\end{pmatrix},$$
Here \( \omega = e^{\frac{2\pi i}{6}} = \frac{1}{2} + i\frac{1}{2}\sqrt{3} \).

## The inverse of \( \text{ad}_J \)

Since \( J \) is an element of the Cartan subalgebra \( \mathfrak{h} \), the eigenvalues of \( \text{ad}_J \) are given by:

\[
[J, E_\alpha] = \alpha(J)E_\alpha, \tag{97}
\]

where the root \( \alpha \in \Delta \). The root system \( \Delta \) of \( D_4 \) splits into positive and negative roots \( \Delta = \Delta^+ \cup \Delta^- \), so that if \( \alpha \in \Delta^+ \) then \( -\alpha \in \Delta^- \). In particular

\[
\Delta^+ \equiv \{e_i \pm e_j, \; i, j = 1..4, \; i < j\}. \tag{97}
\]

The eigenvalues of \( \text{ad}_J \) are given by:

\[
\alpha(J) \equiv (\alpha, \vec{J}), \quad \alpha \in \Delta,
\]

where \( \vec{J} \) is the vector dual to the Cartan element \( J \) (see (17)), so \( \vec{J} = e_1 + \omega e_2 + \omega^5 e_3 \).

As a result, the characteristic polynomial of \( \text{ad}_J \) is:

\[
P(\lambda) \equiv \prod_{\alpha \in \Delta} (\lambda - \alpha(J)) = \prod_{\alpha \in \Delta^+} (\lambda^2 - (\alpha(J))^2). \tag{98}
\]

Using the explicit form of \( \vec{J} \) and \( \Delta^+ \), and the fact that \( \omega = \exp(2\pi i/6) \) after some simplifications we get:

\[
P(\lambda) = (\lambda^6 - 1)^3(\lambda^6 + 27). \tag{99}
\]

Next we note that \( \text{ad}_J \) has an inverse only on its image, i.e. \( \text{ad}_J^{-1} \) is defined on \( D_4 \backslash \mathfrak{h}_{D_4} \). On this subspace of \( D_4 \) \( \text{ad}_J \) satisfies the minimal characteristic polynomial:

\[
\text{ad}^{12}_J + 26\text{ad}^6_J - 27 = 0. \tag{100}
\]

Thus we find:

\[
\text{ad}_J^{-1} = \frac{1}{27} (26 \text{ad}^5_J + \text{ad}^{11}_J). \tag{101}
\]
