Cullins assemble the largest family of ubiquitin ligases by binding with ROC1 and various substrate receptors. CUL4 function is linked with many cellular processes, but its substrate-recruiting mechanism remains elusive. We identified a protein motif, the DWD box (DDB1-binding WD40 protein), and demonstrated the binding of 15 WD40 proteins with DDB1–CUL4A. We provide evidence supporting the critical function of the DWD box and DDB1’s role as the linker mediating DWD protein association with CUL4A. A database search predicts that about one-third of WD40 proteins, 90 in humans, contain the DWD box, suggesting a potentially large number of DWD–DDB1–CUL4–ROC1 E3 ligases.

Received August 16, 2006; revised version accepted September 15, 2006.

The ubiquitin–proteasome pathway regulates the concentration and conformation of many cellular proteins in response to changes in physiological conditions. This pathway consists of a cascade of three activities performed by E1 (ubiquitin-activating), E2 (ubiquitin-conjugating), and E3 (ubiquitin ligase) enzymes (Hochstrasser 1996; King et al. 1996; Hershko and Ciechanover 1998). A critical step in this process is how individual protein substrates are recruited to specific E3 ligases. The RING family represents the major family of E3 ligase complexes and control the ubiquitination of a wide variety of substrates. The substrate recruiting mechanism of CUL4, which has two closely related paralogs, CUL4A and CUL4B, in mammals and presents as a single gene in Schizosaccharomyces pombe, Caenorhabditis elegans, and Drosophila, has remained elusive. Various reports have suggested that CUL4 may assemble multiple ligases to target many different substrates. One protein that has frequently been found in association with these various different CUL4 complexes is DDB1, first identified as a damaged DNA-binding protein (Chu and Chang 1988). The emerging picture is that DDB1 functions as a critical factor for CUL4–ROC ligases and possibly acts as a linker to bridge a substrate receptor[s] to CUL4. This study is directed toward understanding the substrate recruiting mechanism and the architecture of DDB1–CUL4 ligases.

Results and Discussion

CUL4A associates with a potentially large number of cellular proteins

To begin searching for the substrate targeting mechanism of CUL4, we first examined CUL4A complexes in vivo by size-exclusion chromatography to gain an initial view of their size distribution. This study revealed that CUL4A exists in a number of different complexes, varying in size from ~250 kDa to >700 kDa [Fig. 1A]. Notably, two proteins that are critical partners of CUL4A, DDB1 and ROC1, also exist in many different complexes. In comparison, the distribution of most CUL1 complexes is limited to a much narrower size range—smaller than 440 kDa, very similar to that of CAND1, a negative regulator of CRLs that binds to an un neddylated form of cullins and blocks the binding of the SKP1 linker with CUL1 (Liu et al. 2002; J. Zheng et al. 2002; Goldenberg et al. 2004). The distribution of CSN5, the catalytic subunit of the COP9/signalosome, exhibits an almost mutually exclusive pattern from that of CUL1 and CAND1, but yet overlaps significantly with CUL4A. These observations are consistent with the finding that CUL4A molecules...
Human CUL4 associates with potentially multiple WD40 repeat proteins. WDR23 and VprBP, which also contain WD40 repeats (Groisman et al. 2003), were subsequently confirmed by mass spectrometric analysis. (C) Immunopurification and mass spectrometric analysis of CUL4A complexes. CUL4A immunocomplexes were precipitated from human BT474 cells and resolved by SDS-PAGE followed by staining with Coomassie brilliant blue. Bands identified by mass spectrometry are indicated. (D) Clarified lysate from HeLa cells was fractionated over a Superdex 200 gel filtration chromatography column, resolved by SDS-PAGE, and Western blotted with indicated antibodies. 

Identification of a DWD box conserved in DDB1-binding WD40 proteins

One intriguing finding from our preliminary studies of CUL4A-interacting proteins is the identification of two WD40 repeat proteins, WDR23 and VprBP. While neither protein has been functionally characterized or linked with CUL4–DDB1, the significance of this identification is appealing when considering that four previously identified CUL4A-interacting proteins—DDB2, CSA, COP1, and CDT2—also contain WD40 repeats (Groisman et al. 2003; Wertz et al. 2004; Holmberg et al. 2005; Liu et al. 2005). The WD40 repeat is loosely defined at the primary sequence level by a Gly–His dipeptide 10–20 residues N-terminal from a Trp–Asp (WD) dipeptide, and is typically 40 residues in length. WD40 proteins form a propeller-like structure, typically with seven blades, each composed of four anti-parallel β-sheets. There are >700 human WD40 repeat protein entries in the current PFAM database (http://www.sanger.ac.uk/Software/Pfam/index.shtml), corresponding to 320 unique genes after eliminating duplicates and truncated forms. As not all WD40 repeat proteins interact with DDB1 or CUL4 even when overexpressed (see below), it is likely that only a subset of WD40 repeat proteins interact with the DDB1–CUL4A ligase.

To identify the signature motif shared by DDB1-binding WD40 proteins, we carried out extensive primary sequence alignment and computer modeling. The WD40 repeats were first compared using NCBI-Blast searches and the CLUSTAL algorithm, then adjusted manually and continuously refined as more DDB1-binding proteins were experimentally identified (see below). This analysis identified a 16-residue stretch that we refer to as the DWD box (DDB1-binding and WD40 repeat) (Fig. 1D) and is defined by three features. (1) The first 14 residues of the DWD box correspond to the second half of a WD40 repeat. These residues are GXXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXNᴰ,XXN Dtype residues, Asp7, Trp13, and Asp14; five hydrophobic residues (Ile, Leu, or Val) at positions 1, 2, 10, 12, and 15; and three small residues (Ala, Gly, Ser, or Thr) at position 3, 4, and 5. (2) Arg16 following the WD dipeptide is a signature residue of the DWD box. Notably, the Arg residue in the DWD box of DDB2 is mutated in several human patients with xeroderma pigmentosum group E (XP-E), and reduces its binding with DDB1 (see Fig. 3, below; Rapic-Otrin et al. 2003). The crystal structure of the heterotrimeric G protein β³ subunit, a DWD protein (see below), has been solved and shows that several conserved residues, including the Arg16, within the DWD box are located on the protein surface (Sondek et al. 1996), suggesting that these residues might participate in binding with other proteins. (3) A DWD protein usually contains one and sometimes two DWD boxes, but rarely three.

Multiple DWD proteins associate with DDB1–CUL4A

To experimentally test the DWD hypothesis, we randomly chose and expressed a number of putative DWD
proteins and examined their binding with CUL4A–DDB1 by coupled IP-Western assays. Considering DDB1 as a possible linker, we triply transfected plasmids expressing CUL4A, DDB1, and individual WD40 proteins. Association between WD40 proteins and DDB1–CUL4A was determined by either Western blotting of the WD40 protein in the CUL4A immunocomplex or, conversely, blotting either CUL4A or DDB1 protein in the WD40 protein immunocomplex (Fig. 2A,B). DDB2 and CSA, the two best-characterized DWD proteins, interact with DDB1 strongly and were included as positive controls. We have identified thus far 15 novel human WD40 proteins that positively bind with DDB1–CUL4A. Twelve are associated with CUL4A–DDB1 in a readily detectable manner when compared with DDB2 and CSA, including VprBP and WDR23 (Fig. 1C), FBXW5, RBBP7, and Gβ2 (Fig. 2A); WSB1, WSB2, PWP1, and GRWD1 (Fig. 2B); and FBXW8, APG16L, and KATNB1 (Fig. 3B). Three WD40 proteins, NUP43, mβTrCP, and RBPP4, weakly interact with DDB1 and CUL4A (Fig. 2B). COP1 contains conserved WD40 repeats, but not the signature Arg16, and only associates with DDB1–CUL4A weakly in comparison with other WD40 proteins (Fig. 2B). It is currently not clear whether COP1 directly interacts with DDB1 or is bridged by another protein as suggested by the finding that a mutation outside the WD40 repeats in COP1 disrupted its binding with DET1 as well as with DDB1 (Wertz et al. 2004). CDC20, a WD40 protein that is missing several conserved residues, including the signature Arg16 (Fig. 1D), did not detectably interact with DDB1–CUL4A in a reciprocal IP-Western assay (Fig. 2A), suggesting that only a subset of, but not all, WD40 proteins interact with DDB1–CUL4A. Thus, together with three previously reported DDB1-binding WD40 proteins—DDB2, CSA, and COP1—a total of 18 DWD proteins have been demonstrated to bind with DDB1–CUL4A experimentally.

**DWD box is important for DWD proteins binding to DDB1–CUL4A**

To provide evidence supporting the DWD hypothesis, we first determined the in vivo association of endogenous CUL4A with a newly identified DWD protein, RBPP7, to which an antibody is available. RBPP7 was readily detected in the CUL4A immunocomplex and was competed off by molar excess of antigen peptide (Fig. 2A).

Finding that at least two F-box-containing, WD40 repeat proteins, FBXW5 [Fig. 2A] and FBXW8 [Fig. 3A], interact with DDB1–CUL4A is somewhat unexpected given that F-box proteins interact with CUL1. We determined whether the F box is required for the binding of WD40 proteins with DDB1–CUL4A. Binding assays showed that the F-box protein SKP2, which does not contain WD40 repeats, did not interact with CUL4A, and that deletion of the F box from FBXW5 did not seem to affect its binding with CUL4A (Fig. 3A). Two additional WD40 proteins that do not contain an F box, APG16L and KATNB1, were readily detected in the CUL4A immunocomplex in the same binding assay. We therefore conclude that WD40 repeats, but not the F box, are required for interacting with DDB1–CUL4A.

To directly test the DWD hypothesis, we performed site-directed mutagenesis of the DWD box of DDB2 (Fig. 3C). Nine residues in the DWD box were changed to alanine and individual mutant proteins were coex-

![Figure 2.](https://example.com/figure2.png)

**Figure 2.** Multiple WD40 repeat proteins bind with CUL4A–DDB1. [A,B] WD40 proteins were cloned into pcDNA3-myc3 expression vectors and cotransfected into 293T cells with plasmids expressing HA-CUL4A and T7-DDB1. Cell lysates were immunoprecipitated and Western blotted as indicated.

![Figure 3.](https://example.com/figure3.png)

**Figure 3.** Testing the DWD hypothesis. [A] CUL4A associates with endogenous RBPP7. 293T cells were lysed with 0.1% NP-40 lysis buffer and immunoprecipitated with an anti-CUL4A antibody, with or without molar excess of antigen peptide. The immunocomplexes were resolved by SDS-PAGE and Western blotted with indicated antibodies. [B] F-box-and-WD40 proteins FBXW5 and FBXW8 were characterized for binding with DDB1–CUL4A. SKP2 [F-box protein without WD40 repeats] and DDB2 were included as a negative and a positive control, respectively. A mutant of FBXW5 deleting the F box was tested for binding with DDB1–CUL4A along with two additional DWD proteins, APG16L and KATNB1, that do not contain an F box. [C] Individual residues of the DWD box of DDB2 protein were changed to alanine and tested for binding with CUL4A by IP-Western analysis. [D] The conserved arginine of the DWD box is critical for binding with DDB1–CUL4A. The arginines of three DWD proteins were changed to alanine and tested for binding with CUL4A by IP-Western analysis.
pressed with CUL4A. The expression of both CUL4A and DDB2 mutants were verified by direct Western blotting, and DDB2–CUL4A association was determined by IP-Western analysis. DDB2–CUL4A association was nearly completely disrupted by the mutation of the signature Arg at position 16 (corresponding to Arg273 in DDB2), substantially reduced by the mutations of five conserved residues—Leu at position 2 (corresponding to Leu258 in DDB2), Asp at position 7 (Asp264). Ile at position 10 (Ile269), Trp at position 13 (Trp270), and Leu at position 15 (Leu272); and reduced to a lesser extent by the mutation of Ser at position 3 (Ser262). Mutation of Val at position 11 (Val267), which is not highly conserved among the DWD proteins, and another residue, Gln274, outside the DDB box did not appreciably affect DDB2–CUL4A binding.

To further test the DWD hypothesis, we introduced alanine substitutions targeting the signature arginine residue in the DDB box of three additional DWD proteins, CSA, PWP1, and ACF16L. The Arg-to-Ala substitution nearly completely disrupted the binding of DDB1–CUL4A with CSA, and substantially reduced the binding of DDB1–CUL4A with PWP1 and ACF16L [Fig. 3D]. Together, these bioinformatic analysis and binding and mutagenesis experiments demonstrate that the DWD box not only correlates with but also is directly involved in mediating the binding of a subset of WD40 proteins with DDB1–CUL4. Whether the DWD motif is sufficient for binding with DDB1 has not been tested due to the unique structure of WD40 proteins. Each WD40 propeller contains seven blades, and every blade is made of four β-sheets: three from one WD40 repeat and one from the next repeat. The DWD box corresponds to the second and third β-sheets of one blade. These features suggest that while the DWD box is required for binding to DDB1, other residues are likely involved as well and also make it unfeasible to map the binding sequence by deletion analysis without causing conformational collapse of the entire blade.

DDB1 links the DWD protein DDB2 to CUL4A

The results from our binding assays are most consistent with a model where DDB1 functions as a linker to bridge the DWD proteins to CUL4A. To directly test this model, we examined the interaction of DDB2 with CUL4A in more detail. Two hydrophobic helical surfaces in the N-terminal tip of CUL1, H2 and H5, bind with hydrophobic and polar residues from SKP1 to form a large interface. The N-terminal regions of other cullins form similar H2 and H5 helices, which contain residues that are invariably conserved in orthologs, but are different in paralogs [N. Zheng et al. 2002]. We have previously shown that the substitution of residues in the H2 [86LYQAV→86AAAAA] or H5 [90WQDH→90AAAAA] helices of CUL4A substantially reduced DDB1–CUL4A binding [Fig. 3B; Hu et al. 2004]. Binding assays demonstrated that mutation of either the H2 or H5 helix of CUL4A almost completely abolished CUL4A–DDB2 interaction [Fig. 4A]. We noted that the steady-state level of DDB2 was higher when coexpressed with either the H2 or H5 mutant of CUL4A, a finding that is consistent with the possibility that DDB2 is degraded by the DDB1–CUL4A–ROC1 ligase, either as a direct substrate or as a substrate receptor that is degraded after delivering the substrate. Infection of a retrovirus expressing short hairpin RNA (shRNA) targeting DDB1 reduced the steady-state level of DDB1 by >85% in U2OS cells and about half in HeLa cells, did not change the steady-state level of either CUL4A or RBBP7, but substantially reduced the in vivo association of CUL4A–RBBP7 in both U2OS and HeLa cells [Fig. 4B]. Together, these results support a model that DDB1 acts as a linker bridging the binding of DDB proteins and CUL4.

We previously demonstrated that like SKP1–CUL1, the DDB1–CUL4A association is also negatively regulated by CAND1 [Hu et al. 2004]. The model that DDB1 acts as a linker to bring other DWD proteins to CUL4 predicts that CAND1 and DWD proteins would interact with CUL4 in a mutually exclusive manner. To test this prediction, we determined the interactions among these proteins. As expected, CAND1, DDB1, and the DWD protein DDB2 were readily detected in the CUL4A immunocomplex [Fig. 4C]. In the same assay, both DDB1 and CUL4A, but not CAND1, were detected in the DDB2 immunocomplex [Fig. 4C], further supporting the model that DDB1 acts as a linker bridging the binding of DDB protein and CUL4.

A large number of DWD proteins are present in different organisms

A remarkable feature of the cullin family of E3 ligases is the assembly of multiple E3 ligases by each individual
cullin. Despite its linkage with multiple cellular pathways and many putative substrates, the substrate recruiting mechanism for CUL4 has remained elusive. The evidence presented here supports the model that a subset of WD40 proteins, defined by the presence of a WD box, bind to DDB1, and that DDB1 functions as a linker connecting the DWD proteins to CUL4. A DWD protein could either be a substrate itself or function as a substrate receptor to recruit other protein[s] for ubiquitination by the CUL4–ROC catalytic core.

Database searches predict that there may be as many as 90 DWD proteins in humans [Supplementary Fig. 1], 74 in mice [Supplementary Fig. 2], 75 in Drosophila [Supplementary Fig. 3], 36 in C. elegans [Supplementary Fig. 4], 71 in Arabidopsis [Supplementary Fig. 5], 33 in S. pombe [Supplementary Fig. 6], and 20 in Saccharomyces cerevisiae [Supplementary Fig. 7]. These observations suggest that CUL4–ROC1 could potentially form a large family of distinct ubiquitin ligases with individual DWD proteins and target the ubiquitination of many substrate proteins. Among the DWD proteins that have been experimentally tested positive for binding with DDB1–CUL4A are two F-box proteins, FBXW5 and FBXW8, and two SOCS proteins, WSBl and WSBl2 [Fig. 2]. FBXW5 and WSBl1 have been shown to bind with CUL1 and CUL2/5, respectively [Kamura et al. 2001; Arai et al. 2003]. Whether these receptor proteins bind simultaneously with both CUL1 and CUL4 or CUL2/5 and CUL4, and whether cullin heterodimers more efficiently promote substrate polyubiquitination is an interesting possibility that is yet to be tested. The presence of 20 WD40 proteins in the S. cerevisiae genome with the potential to bind with DDB1 is equally intriguing since there is no obvious homolog of either DDB1 or CUL4 in budding yeast. Two obvious candidate linkers for binding with these putative DWD proteins are CPSF160 [the cleavage and polyadenylation specificity factor A, 160-kDa subunit] and SAP130 [spliceosome-associated protein 130]. Both CPSF160 and SAP130 are present in budding yeast and exhibit a low-level similarity with DDB1 at the primary sequence level, but contain similar β-propellers, as predicted by computational modeling [Neuwald and Polelsk 2000] and reinforced by comparison with the DDB1 crystal structure (Li et al. 2006).

Materials and methods

Antibodies, immunopurification, and mass spectrometric analysis

Antibodies to HA [12CA5, Boehringer-Mannheim], Myc [9E10, NeoMarker], T7 [Novagen], and Flag [M2, Sigma] were purchased commercially. Rabbit polyclonal antibodies to CUL4A, DDB1, and CDT1 have been described [Hu et al. 2004]. A rabbit polyclonal antibody against CUL4B was produced by injection of a synthetic peptide antigen to residues 34–62 of CUL4B (AAQFVSATDGNTSTTPSASKKRNLS). A rabbit polyclonal antibody against DDB2 was the kind gift of Dr. Altay Wani (Ohio State University, Columbus, OH). To purify the endogenous CUL4A complex, BT474 cells from 47 150-mm plates were lysed with a 0.5% NP-40 lysis buffer (50 mM Tris-HCl at pH 7.5, 150 mM NaCl, 0.5% NaF, 50 mM NaF), and lysates were pooled (300 mg total). Clarified lysates were immunoprecipitated with affinity-purified anti-CUL4A antibody [2 µg/mg lysate, ±10 µg/mg antigen peptide]. Immunocomplexes were resolved by SDS-PAGE and stained with Coomassie blue, and the protein bands were digested with trypsin and subjected to mass spectrometric analysis at the University of North Carolina Proteomics Core Facility.

Plasmids, cell culture, and cell transfection

Plasmids expressing human CUL4A, DDB1, and CDT1 were as previously described [Ohba et al. 1999; Liu et al. 2002; Furukawa et al. 2003; Hu et al. 2004]. Plasmids expressing DDB2, CSA, and all other WD40 proteins were produced by amplifying cDNA from either human HeLa or thymus (kind gift of Dr. Lishan Su, University of North Carolina, Chapel Hill, NC) cDNA libraries and subcloning into pcDNA3-based mamma-

Zhang, J.G., Fairley, A., Nicholson, S.E., Willson, T.A., Zugaro, L.M., Simpson, R.J., Moritz, R.L., Cary, D., Richardson, R., Haussmann, G., et al. 1999. The conserved SOCS box motif in suppressors of cytokine signaling binds to elongins B and C and may couple bound proteins to proteasomal degradation. *Proc. Natl. Acad. Sci.* 96: 2071–2076. Zheng, J., Yang, X., Harrell, J.M., Ryzhikov, S., Shum, E.H., Lykke-Andersen, K., Wei, N., Sun, H., Kobayashi, R., and Zhang, H. 2002. CAND1 binds to unneddylated CUL1 and regulates the formation of SCF ubiquitin E3 ligase complex. *Mol. Cell* 10: 1519–1526. Zheng, N., Schulman, B.A., Song, L., Miller, J.I., Jeffrey, P.D., Wang, P., Chu, C., Koepp, D.M., Elledge, S.J., Pagano, M., et al. 2002. Structure of the Cul1–Rbx1–Skp1–F boxSkp2 SCF ubiquitin ligase complex. *Nature* 416: 703–709.
