Abstract

Glutamate excitotoxicity is emerging as a contributor to degeneration of spinal cord motoneurons in amyotrophic lateral sclerosis (ALS). Recently, we have reported that ghrelin protects motoneurons against chronic glutamate excitotoxicity through the activation of extracellular signal-regulated kinase 1/2 and phosphatidylinositol-3-kinase/Akt/glycogen synthase kinase-3β pathways. Previous studies suggest that activated microglia actively participate in the pathogenesis of ALS motoneuron degeneration. However, it is still unknown whether ghrelin exerts its protective effect on motoneurons via inhibition of microglial activation. In this study, we investigate organotypic spinal cord cultures (OSCCs) exposed to threohydroxyaspartate (THA), as a model of excitotoxic motoneuron degeneration, to determine if ghrelin prevents microglial activation. Exposure of OSCCs to THA for 3 weeks produced typical motoneuron death, and treatment of ghrelin significantly attenuated THA-induced motoneuron loss, as previously reported. Ghrelin prevented THA-induced microglial activation in the spinal cord and the expression of pro-inflammatory cytokines tumor necrosis factor-α and interleukin-1β. Our data indicate that ghrelin may act as a survival factor for motoneurons by functioning as a microglia-deactivating factor and suggest that ghrelin may have therapeutic potential for the treatment of ALS and other neurodegenerative disorders where inflammatory responses play a critical role.

Key Words: Ghrelin, Neuroinflammation, Microglial activation, Excitotoxicity, Motoneuron

INTRODUCTION

Amyotrophic lateral sclerosis (ALS) is a chronic, progressive neurodegenerative disease for which there is no cure. Individuals with ALS are characterized by the selective loss of motoneurons in the spinal cord, brain stem and motor cortex, which results in a progressive muscle weakness and paralysis [1]. Despite extensive research, the mechanism causing motoneuron death in ALS is still mostly unclear; however, glutamate excitotoxicity has been implicated in neurodegeneration in this disease [2]. Glutamate re-uptake is diminished in synaptosomes from cerebral cortex and spinal cord of ALS patients [3] due to a selective loss of the astroglial glutamate transporter in the motor cortex and spinal cord [4]. These changes result in an excessive concentration of glutamate in the synaptic cleft and the excessive stimulation of glutamate receptors give rise to an increased intracellular concentration of Na⁺ and Ca²⁺, and then this can cause excitotoxic neuronal death [2]. Another common characteristic of ALS is the occurrence of neuroinflammatory reaction [5]. The accumulation of reactive microglia is detected in degenerating areas of ALS patients and transgenic animal models [6,7]. A variety of noxious compounds, such as reactive oxygen species (ROS), reactive nitrogen species, pro-inflammatory cytokines, and prostaglandins, released from inappropriately activated microglia, stimulate ionotropic glutamate receptors leading to enhanced neuronal damage [8-10]. Considering that minocycline, a semisynthetic tetracycline derivatives, is neuroprotective against excitotoxicity by inhibiting activation and proliferation of microglia [11,12], the molecules targeting pharmacological intervention of microglial activation may be plausible therapeutic candidates for neuroprotective agents in ALS.

Ghrelin, a unique peptide esterified with octanoic acid on Ser 3 [13], is a novel 28-amino acid hormone that is principally synthesized and released from Gr cells in the oxyntic mucosa of the stomach [14]. In addition to its potent stimulating effect on growth hormone (GH) release from the anterior pituitary gland, ghrelin induces a positive energy balance by increasing food intake while decreasing fat use...
through GH-independent mechanisms [15,16]. Ghrelin also exerts numerous peripheral effects including direct effects on exocrine and endocrine pancreatic functions, carbohydrate metabolism, the cardiovascular system, gastric secretion, stomach motility, and sleep [13]. We have demonstrated that ghrelin exerts neuroprotective effects in different in vivo and in vitro disease models in which excitotoxicity has been involved, including stroke [17-19] and Parkinson’s disease [20]. Moreover, we recently have reported that ghrelin protects spinal cord motoneurons after glutamate excitotoxicity through the activation of extracellular signal-regulated kinase (ERK) 1/2 and phosphatidylinositol-3-kinase (PI3K)/Akt/glycogen synthase kinase (GSK)-3β pathways [21]. However, it is still unknown whether ghrelin exerts its protective effect in chronic glutamate-induced excitotoxic death of spinal cord motoneurons via inhibition of microglial activation. Given the accumulation of reactive microglia in degenerative areas is one of the cellular events signaling the presence of neuroinflammation in ALS [22] and ghrelin inhibits 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)- and kainic acid (KA)-induced microglial activation [20,23], these findings suggest that ghrelin may protect spinal cord motoneurons after glutamate excitotoxicity through the inhibition of microglial activation. Therefore, in the current study, we investigated if ghrelin treatment prevents microglial activation in chronic glutamate-induced excitotoxicity model using organotypic spinal cord cultures (OSCCs) exposed to an inhibitor of glutamate transport, threo[2-hydroxyaspartate (THA).

METHODS

Materials

Rat ghrelin was obtained from Peptides International (Louisville, KY, USA). Monoclonal antibodies to mouse anti-non-phosphorylated neurofilament H (SMI-32) was purchased from Covance (Princeton, NJ, USA), rat anti-Mac-1 from Chemicon (Carlsbad, CA, USA), and goat anti-tumor necrosis factor (TNF)-α and anti-interleukin (IL)-1β from R&D Systems (Minneapolis, MN, USA). All tissue culture reagents were obtained from Gibco/Invitrogen, and all other reagents were obtained from Sigma (St. Louis, MO, USA) unless otherwise indicated.

Organotypic rat spinal cord cultures and treatments

OSCCs were prepared from lumbar spinal cords of 8-day-old Sprague-Dawley rat pups (P8), as previously described [24]. Briefly, pups were decapitated and the lumbar spinal cords were collected under sterile conditions and transferred to sterile Gey’s balanced salt solution containing glucose (6.4 mg/ml). They were transversely sectioned at 350 μm by using a McIlwain Tissue Chopper (Mickle Laboratory Engineering, Gomshall, Surrey, UK). Five or six complete slices were transferred to 30-mm-diameter Millicell® CM culture plate inserts (0.4 μm, Millipore, Carrigtwohill, Co. Cork, Ireland). The inserts were placed in six-well culture plates (35-mm-diameter, Falcon, Becton-Dickinson, Franklin Lakes, NJ, USA), with 1 ml culture medium: 50% (vol/vol) minimal essential medium with 25 mM Hepes, 25% (vol/vol) heat-inactivated horse serum and 25% (vol/vol) Hank’s balanced salt solution supplemented with D-glucose (25.6 mg/ml, Sigma), 2 mM L-glutamine, 100 U/ml penicillin, and 100 μg/ml streptomycin (Gibco/Invitrogen). Cultures were incubated at 37°C in a 5% CO2/95% air humidified incubator. Medium was changed twice every week. Under these conditions, cultures can be maintained up to 3 months with steady motoneuron survival and preservation of synaptic morphology. All experiments started at least 7 days after the explant procedure. Chronic glutamate excitotoxicity was induced by exposure to THA (for 1 to 3 weeks), a potent glutamate transporter inhibitor, which is known to produce a dose-dependent sustained elevation of glutamate levels causing degeneration of motoneurons [25]. To determine whether ghrelin inhibits THA-induced motoneuron death or microglial activation in OSCCs, cultures were treated with ghrelin (100 nM) or vehicle at the same time as THA. In this study, 100 nM of ghrelin was chosen on the basis of our previous study that this dose of ghrelin exerted a potent protective effect on spinal cord motoneurons [21]. All experiments were performed three times, giving essentially identical results.

Motoneuron counts

Motoneurons in the OSCCs were identified by SMI-32 immunostaining and on the basis of their morphology and size (>25 μm) and their localization in the ventral horn. All motoneurons meeting these criteria were blindly counted in each spinal cord section. A minimum of 15 sections was counted for each experimental condition.

Immunohistochemistry

OSCCs growing in the different experimental conditions were fixed with 4% paraformaldehyde (Sigma) in phosphate-buffered saline for 30 min at room temperature. After blocking with 3% normal goat serum (Vector Laboratories, Burlingame, CA, USA) and 1% bovine serum albumin (BSA) (Sigma), the sections were incubated with primary antibodies to SMI-32 (1:5,000), Mac-1 (1:500), TNF-α (1:200), or IL-1β (1:100) overnight at 4°C. For immunofluorescence, sections were incubated for 1.5 h at room temperature with the appropriate secondary antibody, biotinylated anti-goat IgG (1:2,000; Vector Laboratories) or cy3-conjugated goat anti-rat IgG (1:500, Jackson Immunol-Research, West Grove, PA, USA). Sections were counterstained with DAPI and fluorescence was observed using a Zeiss LSM 510 Meta confocal microscope (Carl Zeiss, Oberkochen, Germany).

Measurement of TNF-α and IL-1β levels in culture medium

The production of TNF-α and IL-1β in the OSCCs was determined in culture supernatants using specific ELISA kits (BioSource International, Inc., Camarillo, CA, USA) according to the manufacturer’s instructions.

Statistical analysis

Data are presented as mean±SEM. Statistical analysis between groups was performed using 1-way ANOVA and Holm-Sidak method for multiple comparisons using Sigma-Stat for Windows Version 3.10 (Systat Software, Inc. Point Richmond, CA, USA). p<0.05 was considered statistically significant.
Ghrelin Inhibits Microglial Activation

Fig. 1. Ghrelin protects spinal cord motoneurons against THA-induced chronic glutamate excitotoxicity. Spinal cord cultures were treated for 3 weeks with 100 μM THA. Either vehicle or ghrelin (100 nM) was added to the culture medium at the same time as THA. Motoneurons were identified by SMI-32 immunostaining and on the basis of their morphology, size and location. Representative micrographs of SMI-32 (+) motoneurons in the ventral horn of the spinal cord are shown. Scale bar represents 100 μm. Values are the mean±SEM of at least 15 sections per treatment. Each experiment was repeated three times. *p < 0.05 vs. control cultures; †p < 0.05 vs. THA-insulted, vehicle-treated cultures.

RESULTS

Ghrelin inhibits spinal cord motoneuron death after THA-induced chronic glutamate excitotoxicity

To investigate the effects of ghrelin on spinal cord motoneurons exposed to chronic glutamate-induced excitotoxicity, OSCCs were incubated with THA, a glutamate-uptake inhibitor, in the presence or absence of ghrelin. After 3-week exposure of OSCC to THA (100 μM), 58.8% of motoneurons were not viable as determined by SMI-32 immunohistochemistry. However, THA-induced motoneuron death was significantly reduced by treatment of ghrelin (100 nM) (Fig. 1), as we previously reported [21].

Ghrelin suppresses THA-induced activation of microglia

It has been reported that a neuroinflammatory response precedes motoneuron death caused by THA-induced glutamate excitotoxicity [26]. To investigate whether the protective effect of ghrelin on spinal cord motoneurons is associated with the inhibition of the THA-induced microglial activation, we examined the expression of Mac-1, which is a specific marker for microglial activation [10]. Immunohistochemical analysis showed that THA resulted in a significant increase in the immunoreactivity of activated microglia after 1 week of treatment with THA and lasted for 3 weeks (Fig. 2). However, in THA- and ghrelin-treated cultures, ventral horn Mac-1 immunoreactivities were significantly reduced when compared with THA- and vehicle-treated group (Fig. 2).

Ghrelin inhibits the production of proinflammatory products derived from activated microglial cells

It is well known that neuroinflammation plays important roles in motoneuron damage in ALS [5,9]. Pro-inflammatory mediators released from activated microglia could be a link between neuroinflammation and excitotoxic spinal cord motoneuron death [5,9]. Given the fact that ghrelin suppressed the THA-induced microglial response, we inves-

Each experiment was repeated three times. *p<0.05 vs. control cultures; †p<0.05 vs. THA-insulted, vehicle-treated cultures.

DISCUSSION

In the present study, we show that ghrelin treatment reduces spinal cord motoneuron death caused by chronic glutamate-induced excitotoxicity, as previously described [21]. The protective effect of ghrelin on motoneurons appears to be mediated by the inhibition of microglial activation and concomitant release of microglia-derived pro-inflammatory mediators.

As we recently reported [21], ghrelin protects spinal cord...
Ghrelin Inhibits Microglial Activation

motoneurons from THA-induced chronic glutamate excitotoxicity in OSCCs. It has been shown that ghrelin exerts its effect through the activation of its receptor GH secretagogue receptor (GHS-R) 1a and activates ERK1/2 and Akt in motoneurons. Ghrelin-induced Akt signaling was also associated with downstream inhibition of GSK-3β in motoneurons [21]. Although these findings suggest a direct role of ghrelin on spinal cord motoneurons, there is a possibility that the neuroprotective effect of ghrelin may be mediated through the influence on non-neuronal cells, such as microglia. As mediators of inflammation, reactive microglialosis is a considerable hallmark of ALS [6,7] and the intensity of microglial activation is correlated with severity of motoneuron damage in human ALS [9], suggesting an active involvement of microglial activation in the disease. Furthermore, we recently demonstrated that ghrelin prevented microglial activation induced by MPTP and KA [20,23]. In agreement with these findings, we show here that ghrelin significantly reduces THA-induced accumulation of reactive microglia in the spinal cord. In that minocycline inhibits the activation and proliferation of microglial cells and protects motoneurons against excitotoxicity [11,12], the inhibitory effect of ghrelin on microglial activation may play an important role in the neuroprotective effect of ghrelin in chronic glutamate excitotoxicity. Additionally, ghrelin may have a direct effect on spinal cord oligodendrocytes because GHS-R1a is expressed in these cells and ghrelin inhibits apoptotic cell death of oligodendrocytes after spinal cord injury [27]. However, the precise role of ghrelin on oligodendrocytes remains to be determined.

Microglia are the primary immune cells of the central nervous system [28]. Activated microglia are capable of producing a variety of noxious compounds, such as ROS (superoxide, nitric oxide, and its derivatives), cytokines, and eicosanoids [8-10]. Pro-inflammatory cytokine levels, including TNF-α and IL-1β, are increased in the central nervous system of ALS patients and in mutant superoxide dismutase 1 transgenic mice [5,9]. These cytokines may increase the susceptibility of motoneurons to glutamate toxicity and inhibit the function and expression of astrocytic glutamate transporters resulting in further neurotoxicity [9]. Consistent with the concept that ghrelin may reduce the THA-induced microglial activation, we found that ghrelin attenuated the expression of TNF-α and IL-1β in the spinal cord. This inhibitory effect of ghrelin on TNF-α and IL-1β may contribute to alleviating THA-induced inflammatory damage. Supporting evidence for this observation is that ghrelin shows anti-inflammatory effect in the periphery [29-31] and in a central hemorrhage model of brain damage [32]. Given the fact that the neuroprotective effect of ghrelin in spinal cord is associated with the inhibition of THA-induced microglial activation, and the subsequent increase in TNF-α and IL-1β, we suggest that ghrelin functions as a microglia-deactivating factor.

Neuroprotective effects of ghrelin have been observed in numerous in vitro and in vivo models of neurodegenerative disorders, including Parkinson’s disease [20,33,34], stroke [17-19], epilepsy [23,35], and ALS [21]. It has been reported that both acylated and des-acyl ghrelin produce neuroprotective effects [18,19]. Both types of ghrelin activate similar intracellular signaling pathways, such as ERK1/2, PI3K/Akt, protein kinase A, and protein kinase C pathways [18]. It is interesting that des-acyl ghrelin has neuroprotective effects independent of ghrelin receptor GHS-R1a [18,19]. Activation of these signaling pathways results in the inhibition of apoptotic cascades through the increase in the Bel-2/Bax ratio, the prevention of cytochrome c release and the inhibition of caspase 3 activation [17-19,27]. Ghrelin prevents ischemia induced activation of p-38 and c-Jun NH2-terminal kinase, which activate the pro-apoptotic events [17]. Moreover, ghrelin suppresses neuroinflammation via the inhibition of microglial activation and subsequent release of pro-inflammatory cytokines [20,23]. In addition, ghrelin promotes and protects nigrostriatal dopaminergic function via a uncoupling protein 2-dependent mitochondrial mechanisms [33]. Taken together, these findings provide evidence that ghrelin acts as a survival factor for neurons, including spinal cord motoneurons, and offer a new perspective on the potential role of this peptide in various neurodegenerative diseases.

In summary, we found that excitotoxic death of motoneurons caused by THA was associated with a neuroinflammatory response characterized by the presence of activated microglia and the increased release of pro-inflammatory mediators, TNF-α and IL-1β, as previously described [26]. We provide the evidence that the neuroprotective effect of ghrelin is mediated by the inhibition of microglial activation and the concomitant release of pro-inflammatory cytokines in the spinal cord. These findings are significant because ghrelin can function as a neuroprotective agent and may have therapeutic potential for the treatment of ALS and other neurodegenerative disorders where inflammatory responses play a critical role.
