The host-guest complex of the common dye, thioflavin T (ThT), and twisted cucurbit[14]uril (tQ[14]) was selected as a fluorescent probe to determine non-fluorescent triazole fungicides, including flusilazole, azoxystrobin, triadimefon, tebuconazole, tricyclazole, flu trifafol, penconazole, and triadimenol isomer A, in an aqueous solution. The experimental results reveal that the ThT@tQ[14] probe selectively responded to flusilazole with significant fluorescence quenching and a detection limit of $1.27 \times 10^{-8}$ mol/L. In addition, the response mechanism involves not only a cooperation interaction—ThT occupies a side-cavity of the tQ[14] host and the triazole fungicide occupies another side-cavity of the tQ[14] host—but also a competition interaction in which both ThT and the triazole fungicide occupy the side-cavities of the tQ[14] host.

Keywords: twisted cucurbit[14]uril, thioflavin T, fluorescent probe, triazole fungicides, flusilazole

INTRODUCTION

Triazole systemic fungicides, particularly flusilazole (1-[[bis(4-fluorophenyl) (methyl)silyl] methyl]-1H-1,2,4-triazole), are widely used in fruit, vegetable, and grain crops during cultivation and storage with high efficiency and good sterilization ability (Figure 1) (Zhang Y. H. et al., 2016). However, they still have somewhat toxic or other undesirable side effects on non-target organisms. Extensive or inappropriate use can cause soil and water pollution, and thus threaten human health (Ma et al., 2016). Therefore, it is necessary to develop sensitive and selective methods for the analysis of triazole fungicides, which are usually present in trace amounts.

The most common analytical method used for the trace determination of triazoles, particularly flusilazole residues in water, is chromatography e.g., liquid chromatography-tandem mass spectrometry (LC-MS/MS) (Garcia-Valcarcel and Tadeo, 2011; Fu et al., 2017), high-performance liquid chromatography (HPLC) with ultraviolet light, diode-array detection (DAD), photodiode-array (PDA) detection (Bordagaray et al., 2013, 2014; Qi et al., 2014; Ma et al., 2016; Zhang Y. H. et al., 2016), gas chromatography (GC) with nitrogen-phosphorous detection (NPD) or electron capture detection (ECD) (Lozowicka et al., 2015; Im et al., 2016), and GC-mass spectrometry (GC-MS) (Tseng et al., 2014; Chu et al., 2015), and with tandem MS (GC-MS/MS) (Xu et al., 2013). Nevertheless, these chromatographic techniques necessitate experienced workers, costly devices, and lengthy specimen preparation. In comparison with the above-mentioned methods, spectrofluorimetry is the most favorable analytical strategy employed to analyze different biological specimens due to its innate simplicity, high sensitivity, and accessibility in the majority of quality-control and clinical laboratories (Yao et al., 2013). However, determination
of the existence of many common triazoles cannot be performed directly using typical fluorimetric techniques since the aqueous solutions with triazoles do not have native fluorescence.

It is noteworthy that the complexation of a fluorescent dye with a macrocycle host can induce significant change in its fluorescence (Zhou et al., 2008; Zhang et al., 2012; Gao et al., 2017). Various macrocyclic compounds, including cyclodextrins, calix[n]arenes, and pillar[n]arenes, have long been employed as the hosts in several macrocyclic-dye supramolecular systems (Choudhury et al., 2010; Lau and Heyne, 2010; Liu et al., 2015b; Sun et al., 2015). In particular, cucurbit[n]urils (Q[n]) are made up of n glycoluril units connected via 2n methylene bridges (Day et al., 2000; Kim et al., 2000; Cong et al., 2016). These hosts have highly polar carbonyl-fringed portals with hydrophobic cavities that can create remarkably stable complexes with different guest molecules (Kim, 2002; Dsouza et al., 2011; Gao et al., 2017; Liu J. et al., 2017; Murray et al., 2017; Yang et al., 2018). The origination of inclusion complexes frequently improves or interrupts the photo-physical and photo-chemical characteristics of the guest molecules. For example, using different Q[n]s to encapsulate some dyes can change the fluorescence characteristics of the guest molecules (Prataetories et al., 2008; Baumes et al., 2009, 2011; Choudhury et al., 2009). The dye@Q[n] complexes can be composed of supramolecular fluorescent probes with high sensitivity and selectivity to recognize and detect analytes, such as metal ions, amines, pesticides, drugs, and DNA (Wheate, 2008; Mohanty et al., 2009; Nau et al., 2009; Zhou et al., 2009; Day and Collins, 2012; Xing et al., 2013; Elbashir and Aboel-Enein, 2015; Liu W. Q. et al., 2017; Xi et al., 2017; Tang et al., 2018; Wang et al., 2018).

Thioflavin T, 3,6-dimethyl-2-(4-dimethylaminophenyl) benzthiazolium cation (ThT) is a benzthiazoliun dye (Figure 1). An aqueous solution of ThT reveals a weak native fluorescence. Nevertheless, as revealed by previous evaluations, the fluorescence of ThT in an aqueous solution can be vastly improved in the presence of Q[7], Q[8], and twisted cucurbit[14]uril (tQ[14]). It was found that ThT can form ThT@Q[n] inclusion complexes with different stoichiometric ratios, which can be applied to identify both alkali-metal and alkaline-earth-metal ions (Choudhury et al., 2009, 2010; Mohanty et al., 2009; Wang et al., 2018). In the present study, a procedure was proposed to determine the residues of triazole fungicides, such as azaconazole, triadimefon, tebuconazole, tricyclazole, flutriafol, penconazole, and triadimenol isomer A in aqueous solution (Figure 1).

RESULTS AND DISCUSSION

Fluorescence Quenching of ThT@tQ[14] With Flusilazole

Previous studies have proven that the fluorescence of ThT in an aqueous solution over a wide range of interaction ratios can be enhanced by its interaction with tQ[14] via different interaction models due to the multiple cavity features of the tQ[14] molecule and two active moieties (the benzothiazole and dimethylaminobenzene moieties) in ThT (Wang et al., 2018). In the current work, we focused on the inclusion complexes of ThT@tQ[14] with 1:1 and 1:5 interaction ratios in the presence of the eight selected triazoles, the corresponding fluorescence spectra of which can be seen in Figure 2 and Figures S1–S3. A significant fluorescence quenching of the ThT@tQ[14] inclusion complex probe (1:1) was only observed upon increasing the amount of flusilazole; ~60% of the fluorescence intensity was lost when C_{flusilazole}/C_{ThT@tQ[14]} was ~4 (Figure 2A). Figure 2B shows the plot of the fluorescence intensity at λ_em = 488 nm upon increasing the flusilazole concentration; K_{observed} was calculated by the nonlinear-least-squares method to be (8.2 ± 0.4) × 10⁵ L/mol obtained (Figure S4), which is likely due to the influence of the interaction of tQ[14] with flusilazole on the interaction of tQ[14] with ThT. Moreover, the ThT@tQ[14] fluorescent probe presented high selectivity for flusilazole because the probe showed little or almost no response to the other seven triazole fungicides studied (Figure 3 and Figure S1). The ThT@tQ[14] inclusion complex probe at a molar ratio of 1:5 was also selected to investigate its response to triazole pesticides with the addition of flusilazole also leading to a fluorescence quenching of the ThT@tQ[14] inclusion complex probe; only ~22% of the fluorescence intensity was lost when C_{flusilazole}/C_{ThT@tQ[14]} was ~4 (Figure S2). However, the ThT@tQ[14] fluorescent probe also showed little or almost no response to the other triazole fungicides studied (Figure S3).

Analytical Characteristics of ThT@tQ[14] Probe

The standard calibration curve (Figure S5) of the complexes of flusilazole with ThT@tQ[14] (1:1) was obtained using the plot of fluorescence intensity F compared to flusilazole concentration. The linear range was (0.0–1.0) × 10⁻⁶ mol/L for flusilazole with a correlation coefficient of 0.9888. For flusilazole, the limit of detection (LOD) was 1.27 × 10⁻⁸ mol/L and the linear regression equation F = −216.24C+576.26. Although the ThT@tQ[14] (1:5) inclusion complex was less sensitive to flusilazole, it still exhibited a very low LOD (2.80 × 10⁻⁸ mol/L) and the linear regression equation was F = −98.25C+863.26 (Figure S6).

Effects of Interfering Substances

In the present work, the impacts of different common interfering substances on the determination of flusilazole using the ThT@tQ[14] probe were also investigated. The tolerance limit was established as the concentration of an added interfering substance that causes a relative error of < ±5% in the flusilazole determination. The samples consisted of a fixed amount of flusilazole (1.0 µM) and ThT@tQ[14] (1.0 µM) with an increasing amount of different interfering substances; the corresponding results are shown in Table 1 and Figure S7. It is clear that the determination was free from interference in the presence of the common metal ions and anions in aqueous solutions, except Ca²⁺. Structural analysis revealed that tQ[14] had a similar portal size to those of Q[6] and...

Preliminary Exploration of the Response Mechanism of ThT@$tQ[14]$ Fluorescent Probe Toward Flusilazole Titration $^1H$ NMR Spectra

We have found that the ThT@$tQ[14]$ fluorescent probe was selectively sensitive toward flusilazole and could be used to detect flusilazole via a significant fluorescence quenching process. Why is the ThT@$tQ[14]$ fluorescent probe selectively sensitive to flusilazole? How does the flusilazole molecule influence the interaction between the ThT molecule with the $tQ[14]$ host molecule? What could the interaction mode be? To understand the selectivity and response mechanism of the ThT@$tQ[14]$ fluorescent probe toward flusilazole, titration $^1H$ NMR spectra were recorded upon the gradual addition of one of the selected triazole fungicides into the solution of the ThT@$tQ[14]$ (1:1) fluorescent probe. The detailed interaction of ThT and $tQ[14]$...
has been discussed in a previous work (Figures 4A,B) (Wang et al., 2018). Figure 4F shows the $^1$H NMR spectrum for the flusilazole in the presence of tQ[14]. When compared with the $^1$H NMR spectrum for the unbound flusilazole molecule (Figure 4G), the proton resonances corresponding to H5 and H6 on the triazole moiety of the bound flusilazole molecule underwent slightly down-field shifts (0.01 and 0.01 ppm, respectively), whereas the other proton resonances experienced slightly up-field shifts, suggesting that a weak interaction existed between tQ[14] and the flusilazole guest molecule or $\pi \cdots \pi$ stacking of the aryl groups of the flusilazole guest molecules. Figures 4C–E show the titration $^1$H NMR spectra for the tQ[14]-ThT complex upon increasing the amount of flusilazole. The addition of flusilazole appeared to pull the bound ThT out of the interaction area of the tQ[14] host because the proton resonances were closer to those of the unbound ThT molecule. However, the proton resonances of flusilazole, in particular, the H5 and H6 experienced down-field shift, suggesting that ThT was still interacting with the host and flusilazole was located in the de-shielding region of tQ[14] (probably at portal area). Similar phenomena could be observed for the other tQ[14]-ThT-triazole fungicide systems, in which the addition of the triazole fungicide could lead to a change in the interaction between tQ[14] and ThT. Moreover, both ThT and the triazole fungicide exhibited an interaction with the tQ[14] host (Figures S10–S16). At first, it seemed that it was difficult to obtain the required information using the titration $^1$H NMR method. A closer inspection revealed that the addition of different triazole fungicides could lead to different chemical shifts for the proton resonances corresponding to the ThT molecule, and the effects of the different triazole fungicides on the bound ThT were compared with the chemical shift corresponding to proton Hg. The data in Table 2 reveal that flusilazole resulted in the larger change in the chemical-shift values ($\Delta \delta = 0.05$) when the tQ[14]-ThT-triazole fungicide ratio was 1:1:2.

2D diffusion-ordered NMR spectroscopy (DOSY) experiments were performed to afford further evidence for the formation of the tQ[14]-ThT-flusilazole (1:1:1) ternary interaction species. Figure S17 depicts the DOSY spectra of tQ[14], ThT, flusilazole, and tQ[14]-ThT-flusilazole (1:1:1) ternary interaction species in D$_2$O at 298 K and the corresponding diffusion coefficients (D) are 3.49 $\times$ 10$^{-10}$, 5.46 $\times$ 10$^{-10}$, 3.88 $\times$ 10$^{-10}$, and 2.92 $\times$ 10$^{-10}$, respectively. According to the values of four species, the tQ[14]-ThT-flusilazole (1:1:1) ternary interaction species is the smallest, suggesting that the ternary species could be the largest species, moreover, all the proton signals of the host and the guest display the same diffusion coefficient ($D = 2.92 \times 10^{-10}$ m$^2$ s$^{-1}$), indicating that they are part of the same species.

**Isotothermal Titration Calorimetry**

Isotermal titration calorimetry (ITC) experiments were conducted to determine the association constants and thermodynamic parameters of the host-guest interaction between tQ[14] and ThT with the triazole fungicides in an aqueous solution to further explore the fluorescence-quenching mechanism of ThT@tQ[14] with flusilazole (Figures S18–S26). From the data acquired (Table 3), all the association constants obtained for the triazole fungicides@tQ[14] complexes

[(1.46–8.39) × 10^5 L/mol] were slight larger than that of the ThT@tQ[14] complex (1.28 × 10^5 L/mol), but there are no significant differences. The titration 1H NMR study has proved that these pesticides could not replace ThT to form pesticide@tQ[14] inclusion complexes.

The fluorescence enhancement mechanism of ThT could be due to the restriction of the freely rotating dimethylamine group on the benzene moiety, making the lone pair electrons on nitrogen atoms conjugate to the ThT aromatic system. The shell-like cavity structure of tQ[14] can provide such controlled environment, the inclusion of dimethylamino phenyl moiety of ThT inhibited dimethylamino free rotation, moreover, the shell-like cavity structure of tQ[14] could prevent ThT from threading through the side cavity of tQ[14] (Liu et al., 2015a; Li et al., 2016). Therefore, we can observe ThT fluorescence enhancement. Unlike HMeQ[6] and Q[7] which have similar portal sizes to that of the side portals of tQ[14], ThT could thread through their cavities, and show a weak fluorescence emission (referring the fluorescence spectra as shown in Figure S27). On the other hand, the fluorescence emission of ThT is also affected by its electron-pushing group (dimethylamine group) and electron-withdrawing group (quaternary ammonium moiety). The titration 1H NMR spectra could provide the interaction images of this ternary system: the flusilazole was located in the deshielding region of tQ[14] (probably at portal area), which caused the chemical shift change of ThT proton resonance to move

toward the free ThT, in particular, the interaction of the azole moiety and quaternary ammonium moiety could weaken the electron-withdrawing capacity of quaternary ammonium moiety, resulting in partial quenching of the fluorescence of the tQ[14]-ThT-flusilazole interaction system (Figure 5). According to the suggested interaction mode, whether the fluorescence quenching of ThT@tQ[14] is caused mainly depends on the interaction of the azole moiety of pesticides and quaternary ammonium moiety of ThT and the ability of pesticides to pull ThT out of the side cavity of tQ[14]. While the NMR and ITC measurement results showed that the flusilazole has the biggest impact, although the differences from other triazole fungicides are subtle.

CONCLUSIONS
In order to further expand the application of Q[n]-based host-guest chemistry, especially the host-guest complexes with fluorescent properties, in detection and recognition, a known host-guest complex of ThT@tQ[14] (1:1) was used as a fluorescent probe to determine non-fluorescence triazole fungicides, including flusilazole, azaconazole, triadimefon, tebuconazole, tricyclazole, flutriafol, penconazole, and triadimenol isomer A. This new and simple fluorometry method proved to be highly selective and sensitive to one of triazole fungicides—flusilazole, and the determination was free from interference by the common metal ions and anions in aqueous solutions, except Ca$^{2+}$. The investigation of the response mechanism revealed that a side-cavity of the tQ[14] host includes the dimethylamino phenyl moiety of ThT, resulting in the ThT fluorescence enhancement; the addition of flusilazole results in the interaction of the azole moiety of flusilazole and quaternary ammonium moiety of ThT, which could weaken the electron-withdrawing capacity of quaternary ammonium moiety, resulting in partial quenching of the fluorescence of the tQ[14]-ThT-flusilazole interaction system. This unusual phenomenon results from the novel structural feature of tQ[14], namely that tQ[14] possesses a central-cavity and two of the same side-cavities.

EXPERIMENT
Materials

rQ[14] was set up and purified in our laboratory according to a procedure detailed in the literature (Cheng et al., 2013). Analytical grade flusilazole (99.5%), azaconazole (99.5%), triadimefon (99.0%), tebuconazole (99.0%), tricyclazole (99.0%), flutriafol (98.6%), penconazole (99.5%), and triadimenol isomer A (95.4%) were purchased from Dr. Ehrenstorfer GmbH (Augsburg, Germany) and used as-received without any further purification. Double-distilled water was used for each of the experiments.

$^{1}$H NMR

Each of the $^{1}$H NMR spectra, including those for titration experiments, were documented at 25°C on a JEOL JNM-ECZ400s spectrometer using SiMe$_4$ as an internal reference. D$_2$O was utilized as a field-frequency lock and the chemical shifts documented in parts per million (ppm).

ITC

Microcalorimetric experiments were conducted with a Nano ITC (TA, USA) isothermal titration calorimeter. Then, 25 consecutive 10-µL aliquots of a 1 mM rQ[14] solution were introduced into the microcalorimetric reaction cell, which contained 1.3 mL of a 0.1-mM guest molecule solution at 25°C. The heat of reaction was...
corrected for the heat of dilution of the guest molecule solution, which was determined in a separate experiment. Each of the solutions were de-gassed before the titration via ultrasonication. Computer simulations (curve fitting) were conducted with Nano ITC analysis software.

Fluorescence Titration

The fluorescence spectra of the host-guest complexes were documented at 25°C using a Varian Cary Eclipse spectrofluorometer (Varian, Inc., Palo Alto, CA, USA). Stock solutions of rQ[14] (1 × 10⁻³ mol L⁻¹), ThT (1 × 10⁻³ mol L⁻¹), and flusilazole (1 × 10⁻⁴ mol L⁻¹) were set up in water. Working solutions were set up by diluting the stock solutions to the necessary concentrations.

A rQ[14]-ThT (1:1) complex solution was set up at a fixed concentration of 1 × 10⁻⁷ mol L⁻¹ in H₂O, which was subsequently combined with flusilazole at guest/host ratios of 0, 0.25:1, 0.5:1, 0.75:1, 1:1, ..., and 4:1. Fluorescence spectrophotometric titrations were established as detailed prior to the standard derivation of 10 measurements without the guest molecule could be determined based on the following relationship: $\sigma = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^2}$, where $n$ is the number of measurements ($n = 11$).

The standard deviation of 10 measurements without the guest molecule could be determined based on the formula LOD = 3σ/$K$.

**AUTHOR CONTRIBUTIONS**

YF, R-HG, YH, and BB undertook the acquisition and analysis of data for the work. ZT and XX drafted the work and revised it critically for important intellectual content.

**ACKNOWLEDGMENTS**

We acknowledge the support of the National Natural Science Foundation of China (Grant No. 21562015), the Creative Research Groups of Guizhou Provincial Education Department (2017-028), and the Innovation Program for High-level Talents of Guizhou Province (No. 2016-5657).
