CONTINUITY OF THE ÁLVAREZ CLASS UNDER DEFORMATIONS

HIRAKU NOZAWA

Abstract. A manifold $M$ with a foliation $\mathcal{F}$ is minimizable if there exists a Riemannian metric $g$ on $M$ such that every leaf of $\mathcal{F}$ is a minimal submanifold of $(M, g)$. For a closed manifold $M$ with a Riemannian foliation $\mathcal{F}$, Álvarez López [1] defined a cohomology class of degree 1 called the Álvarez class whose triviality characterizes the minimizability of $(M, \mathcal{F})$. In this paper, we show that the family of the Álvarez classes of a smooth family of Riemannian foliations on a closed manifold is continuous with respect to the parameter. The Álvarez class has algebraic rigidity under certain topological conditions on $(M, \mathcal{F})$ as the author showed in [20]. As a corollary of these two results, we show that under the same topological conditions the minimizability of Riemannian foliations is invariant under deformations.

1. Introduction

The minimizability of Riemannian foliations. The minimizability of general foliations is characterized in terms of dynamical tools, for example, foliation cycles (Sullivan [26]) or holonomy pseudogroups (Haefliger [12]). On the other hand, remarkably, the minimizability of Riemannian foliations has a strong relation with the topology of manifolds. For example,

- The minimizability of an orientable Riemannian foliation of codimension \( q \) on an orientable closed manifold is characterized by the nontriviality of the basic cohomology of degree \( q \) by a theorem of Masa [14] (see Section 2 of Reinhart [23] or Section 2.3 of Molino [19] for the definition of the basic cohomology).
- For a Riemannian foliation on a closed manifold, Álvarez López [1] defined the Álvarez class, which is a basic cohomology class of degree 1 whose triviality characterizes the minimizability (see Definition 13).
- In particular, this characterization of the minimizability by Álvarez López implies that every Riemannian foliation on a closed manifold with zero first Betti number is minimizable. This is a generalization of a theorem of Ghys [8] on the simply connected case.
- A Riemannian foliation \( F \) on a closed manifold \( M \) is minimizable if \( \pi_1 M \) is of polynomial growth and \( F \) is developable by a result of the author [21].

In this paper, we show that the Álvarez classes of a smooth family of Riemannian foliations on a closed manifold is continuous with respect to the parameter. Combining this result with a rigidity theorem of the Álvarez class in Nozawa [20], we obtain the invariance of the minimizability of Riemannian foliations under deformations under the topological conditions in [20], which implies an algebraic rigidity of Álvarez class there (see Corollary 4 below).

Note that the invariance of the minimizability under deformations does not hold for general foliations. We present examples of families of foliations in Section 8 to describe the situation.

A continuity theorem of the Álvarez class. Our main result is as follows: Let \( M \) be a closed manifold. Let \( U \) be an open neighborhood of 0 in \( \mathbb{R}^\ell \). Let \( \{ F_t \}_{t \in U} \) be a smooth family of Riemannian foliations on \( M \) over \( U \) (see Definitions 11 and 12).

Theorem 1. The Álvarez class \( \xi(F_t) \) of \((M, F_t)\) is continuous in \( H^1(M; \mathbb{R}) \) with respect to \( t \).

Let us mention why Theorem 1 does not follow from the definition of the Álvarez class or the classical deformation theory. By definition, the Álvarez classes of \((M, F_t)\) is represented by the closed 1-form obtained by orthogonally projecting the mean curvature form of \((M, F_t, g^t)\) to the space of basic 1-forms on \((M, F_t)\) for any bundle-like metric \( g^t \) on \((M, F_t)\). But the space of basic 1-forms on \((M, F_t)\) changes discontinuously with respect to \( t \) in the space of 1-forms on \( M \), when the dimension of closures of generic leaves changes. Because of this discontinuity of the spaces of basic 1-forms, we cannot obtain a continuous family of closed 1-forms which represents the Álvarez classes directly from the definition. Furthermore, this discontinuity of the spaces of basic 1-forms breaks the continuity of the domains of
the families of basic Laplacians. Thus we cannot apply the classical technique of deformation theory using smooth families of self-adjoint operators to show Theorem 1 at least directly.

Let us mention why Theorem 1 does not follow from the interpretation of the Álvarez class in terms of the holonomy homomorphism of the Molino’s commuting sheaf of \((M, \mathcal{F}^t)\) by a theorem of Álvarez López [2]. If the dimension of closures of generic leaves changes, the ranks of the family of Molino’s commuting sheaves as flat vector bundles changes. Hence the family of Molino’s commuting sheaves is not smooth as a family of flat vector bundles, and we cannot prove the continuity directly from the result of [2].

To prove Theorem 1, we will take a suitable representative \(\tilde{\kappa}_0\) of the Álvarez class at \(t = 0\), which we will call the \(\tilde{\mathcal{F}}\)-integrated component of the mean curvature form. Then we will approximate the Álvarez class by non-closed 1-forms (see Section 6.3). Some technical consideration on Riemannian foliations will be needed to take the representative \(\tilde{\kappa}_0\) of the Álvarez class at \(t = 0\) in Section 5, which is the main part of this article.

**Deformation of minimizable Riemannian foliations.** Combining Theorem 1 with the characterization of the minimizability by the triviality of the Álvarez class by Álvarez López [1], we have

**Corollary 2.** In parameter spaces of smooth families of Riemannian foliations on closed manifolds, the subsets consisting of parameters corresponding to minimizable Riemannian foliations are closed.

This corollary is not true for general foliations as we will see in Example 8.2.

A foliation \(\mathcal{F}\) is defined to be of polynomial growth if the fundamental group of every leaf of \(\mathcal{F}\) is of polynomial growth. A group \(\Gamma\) is polycyclic if there exists a sequence \(\{\Gamma_i\}_{i=1}^n\) of subgroups of \(\Gamma\) such that \(\Gamma_0 = \Gamma\), \(\Gamma_n = \{1\}\), \(\Gamma_{i-1} \triangleright \Gamma_i\), and \(\Gamma_i/\Gamma_{i+1}\) is cyclic for every \(i\). Let \((M, \mathcal{F})\) be a closed manifold with a Riemannian foliation. If \(\pi_1M\) is polycyclic or \(\mathcal{F}\) is of polynomial growth, then the integration of the Álvarez class of \((M, \mathcal{F})\) along every closed path on \(M\) is the exponential of an algebraic integer by a result of the author [20]. By the totally disconnectedness of the set of algebraic integers in \(\mathbb{R}\), we have the following corollary of Theorem 1.

Let \(M\) be a closed manifold. Let \(U\) be a connected open neighborhood of 0 in \(\mathbb{R}^\ell\). Let \(\{\mathcal{F}^t\}_{t \in U}\) be a smooth family of Riemannian foliations on \(M\) over \(U\) (see Definitions 11 and 12).

**Corollary 3.** If \(\pi_1M\) is polycyclic or \(\mathcal{F}^t\) is of polynomial growth for every \(t\), then \(\xi(\mathcal{F}^t) = \xi(\mathcal{F}^0)\) in \(H^1(M, \mathbb{R})\) for every \(t\).

The Álvarez class changes nontrivially for examples of families of solvable Lie foliations constructed by Meigniez [16] (see also [17]) as we mentioned in [20]. Hence Corollary 3 is not true in general. By the characterization of the minimizability by the triviality of the Álvarez class by Álvarez López [1] and Corollary 3 we have

**Corollary 4.** If \(\pi_1M\) is polycyclic or \(\mathcal{F}^t\) is of polynomial growth for every \(t\), then one of the following holds:

(i) For every \(t\) in \(U\), \((M, \mathcal{F}^t)\) is minimizable.

(ii) For every \(t\) in \(U\), \((M, \mathcal{F}^t)\) is not minimizable.
Note that $\mathcal{F}$ is always of polynomial growth if $\dim \mathcal{F} = 1$. Hence for Riemannian flows, the minimizability is invariant under deformations. As noted above, the invariance of the minimizability under deformations is not true for general foliations. For Riemannian foliations, it is not clear if the minimizability is invariant under deformations in general. We ask

**Question 5.** Is the minimizability of Riemannian foliations on closed manifolds invariant under deformations?

Let $(M, \mathcal{F})$ be a closed 4-manifold with a GA(1)-Lie foliation (see Section 3 for terminologies on Lie foliations). By a theorem of Matsumoto and Tsuchiya [15], $(M, \mathcal{F})$ is a homogeneous GA(1)-Lie foliation up to a finite covering. In particular, $\pi_1 M$ is isomorphic to a finite index subgroup of a lattice in a connected simply connected solvable Lie group. It is well known that a lattice of a connected simply connected solvable Lie group is polycyclic (see Raghunathan [22]). Since it follows from definition that every subgroup of a polycyclic group is polycyclic, $\pi_1 M$ is polycyclic. On the other hand, a GA(1)-Lie foliation on a closed manifold is non-minimizable, and an $\mathbb{R}^2$-Lie foliation on a closed manifold is minimizable. In fact, the following is true:

**Proposition 6.** A $G$-Lie foliation $\mathcal{F}$ on a closed manifold $M$ is minimizable if and only if both of $G$ and $K$ are unimodular, where $K$ is a simply connected Lie group whose Lie algebra is the structural Lie algebra of the Lie foliation on the closure of a leaf of $\mathcal{F}$.

Proposition [6] follows from a generalization of a theorem of Masa [14] by Álvarez López [1] to the non-orientable case and Theorem 1.2.4 of El Kacimi and Nicolau [10] as follows: Let $q = \text{cod}(M, \mathcal{F})$. A theorem of Álvarez López [1] implies that $(M, \mathcal{F})$ is minimizable if and only if the basic cohomology $H^q_b(M/\mathcal{F})$ of degree $q$ is nontrivial. Then Theorem 1.2.4 of El Kacimi and Nicolau [10] implies that $H^q_b(M/\mathcal{F})$ is nontrivial if and only if $G$ and $K$ are unimodular. By the polycyclicity of $\pi_1 M$, Corollary [4] and Proposition [6], we get

**Corollary 7.** A GA(1)-Lie foliation on a closed 4-manifold cannot be deformed into an $\mathbb{R}^2$-Lie foliation.

In dimensions lower than 4, Corollary [7] is easily confirmed to be true as a consequence of classification of Riemannian foliations. In higher dimensions, it is not clear if a similar result is true or not.

**The invariance of basic cohomology of Riemannian foliations under deformations.** Let $U$ be a connected open neighborhood of 0 in $\mathbb{R}^\ell$. Let $\{\mathcal{F}_t\}_{t \in U}$ be a smooth family of Riemannian foliations of codimension $q$ on $M$ over $U$. The dimension of the basic cohomology $H^q_b(M/\mathcal{F})$ of degree $q$ is either of 1 or 0 by a result of El Kacimi, Sergiescu and Hector [11]. As remarked by Álvarez López in the proof of Corollary 6.2 of [1], the triviality of the Álvarez class directly implies the nontriviality of $H^q_b(M/\mathcal{F}^t)$. Hence Corollary [4] is paraphrased to

**Corollary 8.** If $\pi_1 M$ is polycyclic or $\mathcal{F}^t$ is of polynomial growth for every $t$, then we have $H^q_b(M/\mathcal{F}^t) \cong H^q_b(M/\mathcal{F}^0)$ for every $t$ in $U$.

This corollary gives a partial positive answer to the following question asked by the author in the VIII International Colloquium on Differential Geometry at Santiago de Compostela (see [3]):
Question 9. Is the basic cohomology of Riemannian foliations invariant under deformations?

The component of the basic cohomology of the degree equal to the codimension of Riemannian foliations is invariant under deformations if and only if the answer of Question 5 is true. We note that the answer of Question 9 is negative in degree lower than the codimension of Riemannian foliations. We have a simple counterexample as we present in Example 7.4.

Acknowledgement. The author would like to express his deep gratitude to Étienne Ghys and Masayuki Asaoka for stimulative comments on Anosov flows. The author would like to express his deep gratitude to José Ignacio Royo Prieto for pointing out a gap in the previous version of this paper. A part of the correction of this gap was established in the discussion with Jesús Antonio Álvarez López during the author’s stay at the University of Santiago de Compostela in the spring of 2009. The author would like to express his deep gratitude to Jesús Antonio Álvarez López for his invitation, great hospitality and valuable discussion. The author would like to express his deep gratitude to Jesús Antonio Álvarez López also for his comments on this manuscript during the author’s stay at Centre de Recerca Matemàtica in Barcelona in the summer of 2010. The author would like to express his deep gratitude to Centre de Recerca Matemàtica for great hospitality.

2. Basic definitions

2.1. Families of foliations. We use the terminology from Molino [19]. We recall the definition of some basic terminology here to avoid confusion.

Let \((M, F)\) be a foliated manifold. By the integrability of \(F\), the Lie bracket on \(C^\infty(TM)\) induces the Lie derivative with respect to vector fields tangent to the leaves

\[
C^\infty(TF) \otimes C^\infty \left( \bigotimes^r (TM/TF) \otimes \bigotimes^s (TM/TF)^* \right) \rightarrow C^\infty \left( \bigotimes^r (TM/TF) \otimes \bigotimes^s (TM/TF)^* \right)
\]

for all nonnegative integers \(s\) and \(r\).

Definition 10. (i) An element \(X\) of \(C^\infty(TM/TF)\) is called a transverse field on \((M, F)\) if \(L_Y X = 0\) for every \(Y\) in \(C^\infty(TF)\). A vector field \(Y\) on \(M\) is called a basic vector field if \(Y\) is mapped to a transverse field by the projection \(C^\infty(TM) \rightarrow C^\infty(TM/TF)\).

(ii) An element \(g\) of \(C^\infty(\bigotimes^2(TM/TF)^*)\) is called a transverse metric if the following three conditions are satisfied:

1. \(g(Y, Z) = g(Z, Y)\) for every \(Y\) and \(Z\) in \(C^\infty(TM/TF)\),
2. \(L_X g = 0\) for every \(X\) in \(C^\infty(TF)\) and
3. \(g_x(Z, Z) > 0\) for every \(x\) on \(M\) for every nonzero vector \(Z\) in \(T_x M/T_x F\).

A Riemannian metric \(g\) on \(M\) is called a bundle-like metric if the restriction of \(g\) to \(\bigotimes^2(TM/TF)^\perp\) is a transverse metric under the natural identification of \(\bigotimes^2(TM/TF)^\perp\) with \(\bigotimes^2(TM/TF)\).
(iii) Let $q$ be the codimension of $(M, \mathcal{F})$. A transversal parallelism of $(M, \mathcal{F})$ is a $q$-tuple of transverse fields $X^1, X^2, \ldots, X^q$ on $(M, \mathcal{F})$ such that
\{$(X^1)_x, (X^2)_x, \ldots, (X^q)_x$\} is a basis of $T_xM/T_x\mathcal{F}$ at each point $x$ on $M$.

We recall the definition of smooth families of foliations with transverse structures. Let $U$ be an open set in $\mathbb{R}^k$ which contains 0. Let $M$ be a smooth manifold.

**Definition 11.** A smooth family of $p$-dimensional foliations of $M$ over $U$ is defined by a $p$-dimensional smooth foliation $\mathcal{F}^{amb}$ of $M \times U$ such that every leaf of $\mathcal{F}^{amb}$ is contained in $M \times \{t\}$ for some $t$.

For $t$ in $U$, let $\mathcal{F}^t$ be the foliation of $M \times \{t\}$ defined by the collection of the leaves of $\mathcal{F}^{amb}$ contained in $M \times \{t\}$. Families of foliations are written as $\{\mathcal{F}^t\}_{t \in U}$ throughout this paper. $(\nu, \mathcal{F})^{amb}$ denotes the vector bundle over $M \times U$ defined by the kernel of the map $T(M \times U)/T\mathcal{F}^{amb} \rightarrow TU$ induced by the differential map of the second projection $M \times U \rightarrow U$. We call $(\nu, \mathcal{F})^{amb}$ the family of normal bundles of $\{\mathcal{F}^t\}_{t \in U}$. Note that $(\nu, \mathcal{F})^{amb}|_{M \times \{t\}}$ is the normal bundle of the foliation $\mathcal{F}^t$ of $M \times \{t\}$ for each $t$.

**Definition 12.**

(i) A smooth family of Riemannian foliations of $M$ over $U$ is a pair consisting of a smooth family of foliation of $M \times U$ defined by $\mathcal{F}^{amb}$ and a smooth metric $g^{amb}$ on $(\nu, \mathcal{F})^{amb}$ such that the restriction of $g^{amb}$ to the orthogonal normal bundle of $(M \times \{t\}, \mathcal{F}^t)$ is a transverse metric on $(M \times \{t\}, \mathcal{F}^t)$.

(ii) A smooth family of transversely parallelizable foliations of codimension $q$ of $M$ over $U$ is a pair of a smooth family $\{\mathcal{F}^t\}_{t \in U}$ of foliations of $M$ of codimension $q$ and a $q$-tuple of global sections $X^1_{amb}, X^2_{amb}, \ldots, X^q_{amb}$ of $(\nu, \mathcal{F})^{amb}$ such that $\{X^1_{amb}|_{M \times \{t\}}, X^2_{amb}|_{M \times \{t\}}, \ldots, X^q_{amb}|_{M \times \{t\}}\}$ is a transverse parallelism of $(M \times \{t\}, \mathcal{F}^t)$ for each $t$.

### 2.2. The Álvarez class.

We recall the definition of the Álvarez class of a closed manifold with a Riemannian foliation by Álvarez López [1]. We restrict ourselves to the case of oriented manifolds. The definition in the non-orientable case is done by lifting the foliation to the orientation cover as in [1].

Let $(M, \mathcal{F})$ be an oriented closed manifold with a Riemannian foliation. We fix a bundle-like metric $g$ on $(M, \mathcal{F})$. We have a direct sum decomposition
\[
C^\infty(\wedge^k T^* M) = C^\infty_b(\wedge^k T^* M) \oplus C^\infty_b(\wedge^k T^* M)^\perp
\]
with respect to the metric induced by $g$, where $C^\infty_b(\wedge^k T^* M)$ is the space of basic $k$-forms on $(M, \mathcal{F})$. Let $\rho_\mathcal{F}$ be the first projection
\[
\rho_\mathcal{F} : C^\infty(\wedge^k T^* M) \rightarrow C^\infty_b(\wedge^k T^* M).
\]
We denote the mean curvature form of $(M, \mathcal{F}, g)$ by $\kappa$ (see, for example, Section 10.5 of Candel and Conlon [4] for the definition of the mean curvature form of $(M, \mathcal{F}, g)$).

**Definition 13.** For an oriented closed manifold $M$ with a Riemannian foliation $\mathcal{F}$, we define a basic 1-form $\kappa_{amb}$ on $(M, \mathcal{F})$ by
\[
\kappa_{amb} = \rho_\mathcal{F}(\kappa)
\]
and call $\kappa_{amb}$ the Álvarez form of $(M, \mathcal{F})$. This $\kappa_{amb}$ is closed by Corollary 3.5 of Álvarez López [1]. We define the Álvarez class of $(M, \mathcal{F})$ by the cohomology class of $\kappa_{amb}$ in $H^1(M; \mathbb{R})$. We denote the Álvarez class of $(M, \mathcal{F})$ by $\xi(\mathcal{F})$. 

Let $H^1_b(M/F)$ be the basic cohomology group of degree 1 of $(M,F)$ (see Section 2 of Reinhart [23] or Section 2.3 of Molino [19] for the definition of the basic cohomology). Álvarez López defined the Álvarez class as an element of $H^1_b(M/F)$ in [1]. Since the canonical map $H^1_b(M/F) \rightarrow H^1(M/F)$ is injective as easily confirmed by definition, Definition [13] gives the essentially same data as in [1].

The simple proof of the following lemma is due to a comment of Álvarez López to the author:

**Lemma 14.** Let $(M_1,F_1)$ be a closed manifold with a Riemannian foliation. Let $p: M_2 \rightarrow M_1$ be a finite covering, and let $F_2 = p^*F_1$, which is a Riemannian foliation on $M_2$. Then we have $\xi(F_2) = p^*\xi(F_1)$.

**Proof.** We take a bundle-like metric $g_1$ on $(M_1,F_1)$. Then $p^*g_1$ is a bundle-like metric on $(M_1,F_1)$. We consider orthogonal decompositions

\[(4) \quad \Omega^1(M_1) = \Omega^1_b(M_1/F_1) \oplus (\Omega^1_b(M_1/F_1))^\perp,\]
\[(5) \quad \Omega^1(M_2) = \Omega^1_b(M_2/F_2) \oplus (\Omega^1_b(M_2/F_2))^\perp\]

with respect to the metric induced by $g_1$ and $p^*g_1$, respectively. By definition of metrics, we have
\[(6) \quad p^*\Omega^1_b(M_1/F_1) = p^*\Omega^1(M_1) \cap \Omega^1_b(M_2/F_2),\]
\[(7) \quad p^*(\Omega^1_b(M_1/F_1))^\perp = p^*\Omega^1(M_1) \cap (\Omega^1_b(M_2/F_2))^\perp.\]

Let $\rho_{F_1}$ and $\rho_{F_2}$ be the first projections on decompositions (4) and (5), respectively. These equalities imply
\[(8) \quad p^*\rho_{F_1} = \rho_{F_2}p^*.\]

Let $\kappa_i$ be the mean curvature forms of $(M_i,F_i)$ with respect to $g_1$ and $p^*g_1$, respectively. We get $\kappa_2 = p^*\kappa_1$. By (8), we get
\[p^*(\kappa_1)_b = p^*\rho_{F_1}(\kappa_1) = \rho_{F_2}(p^*\kappa_1) = \rho_{F_2}(\kappa_2) = (\kappa_2)_b. \quad \square\]

### 3. Fundamentals of Lie foliation theory

We summarize the fundamental facts of Lie foliation theory due to Fedida [6] and [7] (see also Section 4.2 of Molino [19] or Section 4.3.1 of Moerdijk and Mrčun [13]) to use in Sections 5 and 6.

Let $G$ be a connected Lie group. Recall that a $G$-Lie foliation is a foliation with a transverse $(G,G)$-structure, where $G$ acts on $G$ by the right multiplication. A $G$-Lie foliation has a structure of $G'$-Lie foliation for any covering group $G'$ of $G$ as easily confirmed. Thus we will assume the simply connectedness of $G$ throughout this paper. We recall the following

**Definition 15.** The Lie algebra of $G$ is called the structural Lie algebra of the Lie foliation.

Let $(M,F)$ be a $G$-Lie foliation. Let $p^\text{univ}_M: M^\text{univ} \rightarrow M$ be the universal cover of $M$. Fix a point $x^\text{univ}_0$ in $M^\text{univ}$, and let $x_0 = p^\text{univ}_M(x^\text{univ}_0)$.

(1) We have a fiber bundle dev: $M^\text{univ} \rightarrow G$ which maps $x^\text{univ}_0$ to the unit element $e$ of $G$ and whose fibers are the leaves of the foliation $(p^\text{univ}_M)^*F$ of $M^\text{univ}$. This dev is called the developing map of $(M,F)$. 

(II): We have a group homomorphism \( \text{hol}: \pi_1(M, x_0) \rightarrow G \) such that

\[
\text{dev}(\gamma \cdot x) = \text{dev}(x) \cdot G \text{hol}(\gamma)
\]

for \( x \in M^{\text{univ}} \) and \( \gamma \in \pi_1(M, x_0) \), where \( \cdot G \) is the multiplication of \( G \).

The image of hol is called the holonomy group of \((M, \mathcal{F})\). The holonomy group of \((M, \mathcal{F})\) is dense in \( G \) if and only if the leaves of \( \mathcal{F} \) are dense in \( M \).

(III): Recall that the Maurer-Cartan form \( \theta \) on \( G \) is a Lie\((G)\)-valued 1-form on \( G \) defined by \( \theta_g(v) = (R_g)_*v \) for \( g \in G \) and \( v \in T_gG \), where \( R_g \) is the right multiplication map by \( g \).

Since a Lie\((G)\)-valued 1-form \( \text{dev}^* \theta \) on \( M^{\text{univ}} \) is invariant under the \( \pi_1(M, x_0) \)-action, \( \text{dev}^* \theta \) induces a Lie\((G)\)-valued 1-form \( \Omega \) on \( M \). The structure of a \( G \)-Lie foliation \((M, \mathcal{F})\) is determined by this Lie\((G)\)-valued 1-form \( \Omega \) on \( M \). This \( \Omega \) is called the Maurer-Cartan form of a \( G \)-Lie foliation \((M, \mathcal{F})\).

(IV): The Maurer-Cartan form \( \Omega \) of a \( G \)-Lie foliation \((M, \mathcal{F})\) satisfies the equation

\[
d\Omega + \frac{1}{2}[\Omega, \Omega] = 0.
\]

Conversely, if a Lie\((G)\)-valued 1-form \( \Omega \) on \( M \) satisfies \((10)\) and \( \Omega_x: T_xM \rightarrow \text{Lie}(G) \) is surjective for every \( x \) in \( M \), then \( \Omega \) is the Maurer-Cartan form of a \( G \)-Lie foliation of \( M \).

(V): Let \( q = \text{cod}(M, \mathcal{F}) \). Let \( \{X^i\}_{i=1}^q \) be a basis of \( \text{Lie}(G) \). Let \( \{\overline{X}^i\}_{i=1}^q \) be the dual basis of \( \text{Lie}(G)^* \). Let \( \omega_i \) be the 1-form on \( M \) induced from a \( \pi_1(M, x_0) \)-invariant 1-form \( \text{dev}^* \overline{\omega}_i \) on \( M^{\text{univ}} \). Let \( X^j \) be the vector field on \( M \) orthogonal to \( T\mathcal{F} \) such that \( \omega_i(X^j) = \delta_{ij} \) for each \( i \) and \( j \), where \( \delta_{ij} \) is the Kronecker delta. Then \( \{X^j\}_{j=1}^q \) is clearly a transverse parallelism of \((M, \mathcal{F})\). Here, the Maurer-Cartan form \( \Omega \) of \((M, \mathcal{F})\) is given by the equation \( \Omega_x((X^j)_x) = \overline{X}^j \) for each point \( x \) on \( M \).

4. Reduction to the orientable transversely parallelizable case

We reduce the proof of Theorem 1 to the case where \( \{\mathcal{F}^1\}_{t \in U} \) is a family of transversely parallelizable foliations.

Let \( \{\mathcal{F}^1\}_{t \in U} \) be a smooth family of Riemannian foliations of codimension \( q \) of a closed manifold \( M \) over \( U \). Clearly we can assume that \( U \) is contractible without loss of generality. Let \( \text{Fr}(\nu\mathcal{F})^{\text{amb}} \) be the family of the frame bundles associated with the family \( (\nu\mathcal{F})^{\text{amb}} \) of vector bundles on \( M \). The metric \( g^{\text{amb}} \) on \( (\nu\mathcal{F})^{\text{amb}} \) determines an \( O(q) \)-reduction \( O(\nu\mathcal{F})^{\text{amb}} \) of \( \text{Fr}(\nu\mathcal{F})^{\text{amb}} \). We denote \( O(\nu\mathcal{F})^{\text{amb}}|_{M \times \{0\}} \) by \( O(\nu\mathcal{F})^0 \).

Since \( O(\nu\mathcal{F})^{\text{amb}} \) is the total space of a \( O(\nu\mathcal{F})^0 \)-bundle over a contractible base space \( U \), we can trivialize \( O(\nu\mathcal{F})^{\text{amb}} \) as \( O(\nu\mathcal{F})^{\text{amb}} \cong O(\nu\mathcal{F})^0 \times U \). By the standard construction of the Molino theory, we have the following lemma:

**Lemma 16.** There exists a foliation \( G^{\text{amb}} \) of \( O(\nu\mathcal{F})^0 \times U \) and a \( \frac{2(q+1)}{2} \)-tuple of transverse fields of \( (O(\nu\mathcal{F})^0 \times U, G^{\text{amb}}) \) defining a smooth family \( \{G^1\}_{t \in U} \) of transversely parallelizable foliations of codimension \( \frac{q(q+1)}{2} \) of \( O(\nu\mathcal{F})^0 \) over \( U \).

**Proof.** Let \( \{(V_\lambda, \phi_\lambda)\} \) be a Haefliger cocycle defining a foliation \( \mathcal{F}^{\text{amb}} \) of \( M \times U \). Then \( \{(O(\nu\mathcal{F})^{\text{amb}}|_{V_\lambda}, d\phi_\lambda)\} \) is a Haefliger cocycle on \( O(\nu\mathcal{F})^{\text{amb}} \), where \( d\phi_\lambda \) is the map induced on the frame bundle by \( \phi_\lambda \). We define a foliation \( G^{\text{amb}} \) of
Let $\pi: O(\nu F)^0 \times U \rightarrow M \times U$ be the projection. By Lemma 7 of Nozawa [20], we have $(\pi|_{O(\nu F)^0 \times \{t\}})^* \xi(F^t) = \xi(G^t)$ for each $t$. Since $(\pi|_{O(\nu F)^0 \times \{t\}})^*: H^1(M \times \{t\}; \mathbb{R}) \rightarrow H^1(O(\nu F)^0 \times \{t\}; \mathbb{R})$ is injective, the continuity of $\xi(F^t)$ follows from the continuity of $\xi(G^t)$. 

By Lemmas [14] and [17] we have the following

**Lemma 18.** The general case of Theorem 7 follows from the special case where

(i) $\{F^t\}_{t \in U}$ is a smooth family of transversely parallelizable foliations of $M$.

(ii) $M$ and the basic fibration of $F^0$ are orientable. Moreover if we have another foliation $\tilde{F}$ on $M$, we can assume that $\tilde{F}$ is also orientable.

Here, $\tilde{F}$ in the statement of (ii) will be $\tilde{F}^0$ which appears in Section 6.2. For the proof of Lemma 18 we note that the finite covering $p: M_1 \rightarrow M_2$ induces an injection $p_*: H^1(M_1; \mathbb{R}) \rightarrow H^1(M_2; \mathbb{R})$. Then $p^*: H^1(M_2; \mathbb{R}) \rightarrow H^1(M_1; \mathbb{R})$ is injective by the Poincaré duality for closed manifolds $M_1$ and $M_2$.

5. A representative $\tilde{\kappa}_b$ of the Álvarez class

**5.1. Definition of the $\tilde{F}$-integrated component $\tilde{\kappa}_b$ of the mean curvature form.** We will define the $\tilde{F}$-integrated component $\tilde{\kappa}_b$ of the mean curvature form for transversely parallelizable foliations in a way similar to that of the definition of the Álvarez form $\kappa_b$ for transversely parallelizable foliations in Álvarez López [1]. Let $(M, F)$ be a closed manifold with a transversely parallelizable foliation. Let $q = \text{cod}(M, F)$. We take a transverse parallelism $\{X^j\}_{j=1}^{\text{cod}(M, F)}$ of $(M, F)$. Let $\{\omega_i\}_{i=1}^q$ be the set of basic 1-forms on $(M, F)$ such that $\omega_i(X^j) = \delta_{ij}$, where $\delta_{ij}$ is the Kronecker’s delta. Let

$$\omega_j = \omega_{i_1} \wedge \omega_{i_2} \wedge \cdots \wedge \omega_{i_k}$$

for a set $I = \{i_1, i_2, \ldots, i_k\}$, where $1 \leq i_1 < i_2 < \cdots < i_k \leq q$. Assume that we have the following diagram:

$\begin{array}{ccc}
M & \xrightarrow{\pi_b} & W \\
\pi_F \downarrow & & \downarrow \\
V & \xrightarrow{\pi} & \end{array}$

where $\pi_b: M \rightarrow W$ is the basic fibration of $(M, F)$ and $\pi_F$ is a submersion. Recall that the basic fibration of $(M, F)$ is a fiber bundle whose fibers are closures of leaves of $(M, F)$. We denote the foliations of $M$ defined by the fibers of $\pi_b$ and $\pi_F$ by
\( F_b \) and \( \tilde{F} \), respectively. From now on we denote \( W \) and \( V \) by \( M/F_b \) and \( M/\tilde{F} \), respectively.

We assume that \( M \) and the fiber bundle \( \tilde{\pi} \) are orientable. We fix a bundle-like metric \( g \) on \((M,\mathcal{F})\). Then we define a map \( \rho_{\tilde{\pi}} \) by

\[
(13) \quad \rho_{\tilde{\pi}} \left( \tau + \sum_{I \subset \{1,2,\ldots, q\}, \vert I \vert = k} f^I \omega_I \right) = \\
\frac{1}{\pi_{\tilde{\pi}}^*(\int_{\tilde{\pi}} \text{vol}_{\tilde{\pi}})} \sum_{I \subset \{1,2,\ldots, q\}, \vert I \vert = k} \left( \int_{\tilde{\pi}} f^I \text{vol}_{\tilde{\pi}} \right) \omega_I
\]

for \( f^I \) in \( C^\infty(M) \) and \( \tau \) in \( C^\infty(T^*F \otimes (\wedge^{k-1}T^*M)) \), where \( \int_{\tilde{\pi}} \) is the integration along the fiber of \( \tilde{\pi} \) with respect to the fixed orientation and \( \text{vol}_{\tilde{\pi}} \) is the fiberwise volume form of \( \tilde{\pi} \) determined by the metric \( g \). Note that we have a direct sum decomposition

\[
(14) \quad C^\infty(\wedge^k T^*M) = (\ker \rho_{\tilde{\pi}})^\perp \oplus \ker \rho_{\tilde{\pi}}
\]

and \( \rho_{\tilde{\pi}} \) is the first projection like in the case of \( \rho_F \).

**Definition 19.** We define the \( \tilde{\mathcal{F}} \)-integrated component \( \tilde{\kappa}_b \) of the mean curvature form \( \kappa \) of \((M,\mathcal{F},g)\) with respect to the transverse parallelism \( \{\omega_i\}_{i=1}^q \) by

\[
(15) \quad \tilde{\kappa}_b = \rho_{\tilde{\mathcal{F}}} \kappa.
\]

Note that \( \rho_{\tilde{\mathcal{F}}} \) coincides with \( \rho_{\mathcal{F}} \) and \( \tilde{\kappa}_b = \kappa_b \) if \( \tilde{\mathcal{F}} = \mathcal{F} \). It is the situation originally considered in Álvarez López [1].

Note that \( \rho_{\tilde{\mathcal{F}}} \) depends on the choice of the transverse parallelism \( \{X^j\}_{j=1}^q \). This is different from the case of \( \rho_{\mathcal{F}} \), which is determined only by the metric \( g \). We remark that there will be a natural choice of \( \{\omega_i\}_{i=1}^q \), when we apply this construction in Section 5.1. Note that

\[
(16) \quad \rho_{\tilde{\mathcal{F}}} \rho_{\mathcal{F}} = \rho_{\tilde{\mathcal{F}}}
\]

by definition.

Note that \( \tilde{\kappa}_b \) may not be closed, while the Álvarez form \( \kappa_b \) is closed by Corollary 3.5 of Álvarez López [1]. We do not define \( \tilde{\kappa}_b \) for the case where \( M \) or \( \pi_{\tilde{\pi}} \) is not orientable. This is because it is not used in this paper.

5.2. The statement of Proposition 21 We will state Proposition 21 which asserts that the Álvarez class of \((M,\mathcal{F})\) is represented by \( \tilde{\kappa}_b \) under certain conditions. These conditions will be naturally satisfied in our application in Section 6. The proof of the essential part of Proposition 21 occupies the rest of this section.

In this section we continue to use the notation defined in Section 5.1. Let \( d_{1,0} \) be the composition of the de Rham differential and the projection \( C^\infty(\wedge^{\ast+1} T^*M) \rightarrow C^\infty(\wedge^\ast (T^*\tilde{\mathcal{F}}^\perp) \otimes \wedge^\ast T^*\tilde{\mathcal{F}}) \) determined by \( g \).

**Lemma 20.** If each leaf of \((M,\tilde{\mathcal{F}})\) is minimal with respect to \( g \), then the function \( \int_{\tilde{\pi}} \text{vol}_{\tilde{\pi}} \) on the leaf space \( M/\tilde{\mathcal{F}} \) is constant.

**Proof.** By the assumption, we have \( \kappa_{\tilde{\pi}} = 0 \). By the Rummler’s formula (see the second formula in the proof of Proposition 1 in Rummler [24] or Lemma 10.5.6 of
Candel and Conlon \[4\]), we have $d_{1,0} \vol \tilde{\mathcal{F}} = -\kappa \tilde{\mathcal{F}} \wedge \vol \tilde{\mathcal{F}}$. Hence we have $d_{1,0} \vol \tilde{\mathcal{F}} = 0$. Then

\begin{equation}
    d \left( \int \tilde{\mathcal{F}} \vol \tilde{\mathcal{F}} \right) = \int \tilde{\mathcal{F}} d \vol \tilde{\mathcal{F}} = \int \tilde{\mathcal{F}} d_{1,0} \vol \tilde{\mathcal{F}} = 0.
\end{equation}

Here the second equality follows from the degree counting of the differential forms. □

**Proposition 21.** We assume that $M$, $\tilde{\mathcal{F}}$ and the basic fibration $\pi_b$ of $(M, \mathcal{F})$ are orientable. We also suppose that

(a): The fixed bundle-like metric $g$ on $(M, \mathcal{F})$ is bundle-like also with respect to $\tilde{\mathcal{F}}$.

(b): Each leaf of $(M, \tilde{\mathcal{F}})$ is minimal with respect to $g$.

(c): We define functions $c_{ij}^k$ on $M$ by

\begin{equation}
    d\omega_i = \sum_{1 \leq j < k \leq q} c_{ij}^k \omega_j \wedge \omega_k.
\end{equation}

Then $c_{ij}^k |_{\tilde{\mathcal{F}}}$ is a constant for each fiber $\tilde{\mathcal{F}}$ of $\pi_b$.

(d): Let $\proj_{\tilde{\mathcal{F}}}: C^\infty(TM/T\mathcal{F}) \to C^\infty(TM/T\tilde{\mathcal{F}})$ be the canonical projection. Then $\proj_{\tilde{\mathcal{F}}} X_i$ is a transverse field on $(M, \tilde{\mathcal{F}})$ for each $i$.

Then we have

(i) $\tilde{\kappa}_b$ is a closed 1-form on $M$ and

(ii) $[\kappa_b] = [\tilde{\kappa}_b]$ in $H^1(M; \mathbb{R})$.

We will show (i) here. (ii) will be shown at the end of this section.

**Proof of Proposition 21 (i).** By Lemma 20, the function $\pi^*_b \left( \int \tilde{\mathcal{F}} \vol \tilde{\mathcal{F}} \right)$ on $M$ is constant. Let

\begin{equation}
    C = \pi^*_b \left( \int \tilde{\mathcal{F}} \vol \tilde{\mathcal{F}} \right),
\end{equation}

and

\begin{equation}
    \kappa_b = \sum_{i=1}^q h^i \omega_i.
\end{equation}

By the condition (c), we have

\begin{equation}
    \rho_{\tilde{\mathcal{F}}} \left( \sum_{i=1}^q h^i d\omega_i \right) = \sum_{i=1}^q \left( \int \tilde{\mathcal{F}} h^i \vol \tilde{\mathcal{F}} \right) d\omega_i.
\end{equation}

Using (15), (16) and (3), in this order, we have

\begin{equation}
    \tilde{\kappa}_b = \rho_{\tilde{\mathcal{F}}} \kappa = \rho_{\tilde{\mathcal{F}}} \rho_{\mathcal{F}} \kappa = \rho_{\tilde{\mathcal{F}}} \kappa_b.
\end{equation}
We have
\[ d\bar{\kappa}_b = d\rho \tilde{\kappa}_b \]
\[ = d\rho \tilde{\kappa}_b \]
\[ = \frac{1}{\tilde{\rho}} \sum_{i=1}^{q} (\int_{\tilde{F}} h^i \, \text{vol}_{\tilde{F}}) \omega_i + \frac{1}{\tilde{\rho}} \sum_{i=1}^{q} (\int_{\tilde{F}} h^i \, d\text{vol}_{\tilde{F}}) \omega_i + \frac{1}{\tilde{\rho}} \sum_{i=1}^{q} (\int_{\tilde{F}} h\, d\omega_i) \]
\[ = \rho \tilde{\kappa} \left( \sum_{i=1}^{q} dh^i \wedge \omega_i \right) + \frac{1}{\tilde{\rho}} \sum_{i=1}^{q} (\int_{\tilde{F}} h^i \, \text{vol}_{\tilde{F}}) \wedge \omega_i + \rho \tilde{\kappa} \left( \sum_{i=1}^{q} h^i \, d\omega_i \right) \]
\[ = \rho \tilde{\kappa} \left( d\left( \sum_{i=1}^{q} h^i \omega_i \right) \right) + \frac{1}{\tilde{\rho}} \sum_{i=1}^{q} (\int_{\tilde{F}} h^i \, d\text{vol}_{\tilde{F}}) \wedge \omega_i \]
\[ = \rho \tilde{\kappa} \left( d\left( \sum_{i=1}^{q} h^i \omega_i \right) \right) + \frac{1}{\tilde{\rho}} \sum_{i=1}^{q} (\int_{\tilde{F}} h^i \, d_{1,0} \text{vol}_{\tilde{F}}) \wedge \omega_i \]
\[ = \rho \tilde{\kappa} (d\kappa_b) - \frac{1}{\tilde{\rho}} \sum_{i=1}^{q} (\int_{\tilde{F}} h^i \kappa \tilde{\kappa} \wedge \text{vol}_{\tilde{F}}) \wedge \omega_i. \]

Here, in the first equality, we combined the first and the third terms. The second equality follows from degree comparison. The third equality follows from (20) and the Rummler’s formula (see the second formula in the proof of Proposition 1 in Rummler [24] or Lemma 10.5.6 of Candel and Conlon [4]).

The first term of the last line is 0, because $\kappa_b$ is closed by Corollary 3.5 of Álvarez López [1]. Since $\kappa_{\tilde{F}}$ is 0 by the condition (b), the second term is also 0. Hence (i) is proved.

### 5.3. $\xi(\mathcal{F}) = [\bar{\kappa}_b]$ on the fibers of $\pi_{\tilde{F}}$

We will show a lemma which will be used in the proof of Proposition 21 to show the restriction of $\xi(\mathcal{F})$ to $[\bar{\kappa}_b]$ to the fibers of $\pi_{\tilde{F}}$ are equal. Here, $\alpha$ will be considered to be $\xi(\mathcal{F}) - [\bar{\kappa}_b]$ in the application in Section 5.6.

**Lemma 22.** Assume that the conditions (a) and (b) of Proposition 21 are satisfied. Let $M'$ be an orientable submanifold of $M$ which is a union of fibers of $\pi_{\tilde{F}}$. Let $\{\phi_t\}_{t \in [0,1]}$ be the flow on $M'$ generated by a vector field $X$ on $M'$. Assume that $\omega_i(X)$ is constant on each fiber of $\pi_{\tilde{F}}$ for each $i$. Then we have

\[ \int_{M'} \left( \int_{\gamma_x} \kappa_b \right) \text{vol}_{M'}(x) = \int_{M'} \left( \int_{\gamma_x} \bar{\kappa}_b \right) \text{vol}_{M'}(x), \]

where $\gamma_x$ is the orbit of $x$ of $\{\phi_t\}_{t \in [0,1]}$, and $\text{vol}_{M'}$ is the volume form on $M'$ determined by $g$.

**Proof.** The function $\pi_{\tilde{F}}(\int_{\tilde{F}} \text{vol}_{\tilde{F}})$ on $M'$ is constant by the condition (b) and Lemma 20. We take a real number $C$ and functions $h^i$ on $M$ as (19) and (20).
Then we have
\[
\begin{align*}
\int_{M'} \left( f_{\gamma_x} \alpha_{\tilde{F}}(\kappa) \right) \text{vol}_{M'}(x) \\
= \int_{M'} \left( f_{\gamma_x} \alpha_{\tilde{F}}(\kappa_0) \right) \text{vol}_{M'}(x) \\
= \frac{1}{C} \int_{M'} \left( f_{\gamma_x} \left( \sum_{i=1}^{q} \int_{\tilde{F}} h^i \text{vol}_{\tilde{F}} \right) \omega_i \right) \text{vol}_{M'}(x) \\
= \frac{1}{C} \int_{M'} \left( \int_{0}^{1} \left( \sum_{i=1}^{q} \int_{\tilde{F}} h^i \text{vol}_{\tilde{F}} \right) \gamma_{\tau_x(t)}(X) \omega_i(X) \gamma_{\tau_x(t)}(t) \right) \text{vol}_{M'}(x)
\end{align*}
\]

Here, we used (24) in the first equality. We used (14) and (20) in the second equality.

By the assumption, \( \omega_i(X) \) is constant on the fibers of \( \pi_{\tilde{F}} \). Then we have
\[
\begin{align*}
\frac{1}{C} \int_{M'} \left( \int_{0}^{1} \left( \int_{\tilde{F}} h^i \text{vol}_{\tilde{F}} \right) \gamma_{\tau_x(t)}(X) \omega_i(X) \gamma_{\tau_x(t)}(t) \right) \text{vol}_{M'}(x)
\end{align*}
\]

By the condition (a), we have \( \int_{M'} f \text{vol}_{M'} = \int_{M'/\tilde{F}} \left( \int_{\tilde{F}} f \text{vol}_{\tilde{F}} \right) \text{vol}_{M'/\tilde{F}} \) for a function \( f \) on \( M' \), where \( \text{vol}_{M'/\tilde{F}} \) is the volume form on \( M' \) determined by \( g \).

Hence we have
\[
\begin{align*}
\int_{M'} \left( \int_{\tilde{F}} \left( \int_{\gamma_x} \kappa_b \right) \text{vol}_{\tilde{F}} \right) \text{vol}_{M'}(x)
\end{align*}
\]

The proof of Lemma 22 is completed. \( \square \)

We fix a point \( x_0 \) in \( M \). Let \( \tilde{F} \) be the fiber of \( \pi_{\tilde{F}} \) containing \( x_0 \). Let
\[
(24) \quad q_{\tilde{F}} = \text{cod}(\tilde{F}, F|_{\tilde{F}}).
\]

We assume that the condition (d) of Proposition 21 is satisfied. We define transverse fields \( Y^1, Y^2, \ldots, Y^q \) on \( (M, F) \) by
\[
(25) \quad Y^j = \sum_{i=1}^{q} a_{ij}^j X^i,
\]
where we choose a nondegenerate matrix \((a_{ij}^j)_{1 \leq j \leq q, 1 \leq i \leq q}\) so that \((Y^1)_{x_0}, (Y^2)_{x_0}, \ldots, (Y^q)_{x_0}\) are tangent to \( \tilde{F} \). By the condition (d) of Proposition 21, the vector fields \( Y^1, Y^2, \ldots, Y^q \) are basic with respect to \( \tilde{F} \). Hence \( Y^1, Y^2, \ldots, Y^q \) are tangent to \( F \) at every point of \( F \). We denote the vector subspace \( \bigoplus_{j=1}^{q} \mathfrak{R}(Y^j|_{\tilde{F}}) \) of the Lie algebra of transverse fields on \((\tilde{F}, F|_{\tilde{F}})\) by \( \mathfrak{g} \). Then:
Lemma 23. Assume that the conditions (c) and (d) of Proposition 21 are satisfied.

(i) \( g \) is a Lie subalgebra of the Lie algebra of transverse fields on \((\tilde{F}, \mathcal{F}|_{\tilde{F}})\).

(ii) \((\tilde{F}, \mathcal{F}|_{\tilde{F}})\) is a Lie foliation.

Proof. Let us prove (i). We take basic 1-forms \( \zeta_i \) by \( \zeta_i(Y^j) = \delta_{ij} \), where \( \delta_{ij} \) is the Kronecker’s delta. By the condition (c), we have

\[
d\zeta_i = \sum_{1 \leq j < k \leq q} c^j_{ik} \zeta_j \wedge \zeta_k,
\]

where \( c^j_{ik} \) are functions on \( M \) whose restrictions to \( \tilde{F} \) are constant. Clearly, we have

\[
\zeta_i([Y^j, Y^k]) = -2d\zeta_i(Y^j, Y^k) = -2c^j_{ik}.
\]

For any transverse field \( Z \) on \((M, \mathcal{F})\), we have \( Z = \sum_{i=1}^q \zeta_i(Z)Y^i \). Hence we have

\[
[Y^j, Y^k] = \sum_{i=1}^q \zeta_i([Y^j, Y^k])Y^i = -2 \sum_{i=1}^q c^j_{ik}Y^i.
\]

Recall the notation \( q_{\tilde{F}} = \text{cod}(\tilde{F}, \mathcal{F}|_{\tilde{F}}) \). Consider the case of \( 1 \leq j < k \leq q_{\tilde{F}} \). Note that \([Y^j, Y^k]\) is also tangent to \( \tilde{F} \) at every point on \( \tilde{F} \) because \( Y^j \) and \( Y^k \) are tangent to \( F \) at every point on \( \tilde{F} \). Then \( c^j_{ik} \) must be 0 for \( q_{\tilde{F}} + 1 \leq i \leq q \) by (28), because \( Y^{q+1}, \ldots, Y^q \) are not tangent to \( F \) at \( x_0 \). Hence \([Y^j, Y^k]\) is contained in \( g \). Thus (i) is proved.

Let us prove (ii). Here, \( g \) is a Lie algebra by (i). We define a \( g \)-valued 1-form \( \Omega \) on \( \tilde{F} \) by

\[
\Omega_x((Y^j)_x) = Y^j
\]

for every point \( x \) on \( \tilde{F} \) and every \( j \). For the proof of (ii), it suffices to show that \( \Omega \) satisfies the Maurer-Cartan equation \( d\Omega + \frac{1}{2}[\Omega, \Omega] = 0 \) by (III) and (IV) of Section 3.

This is proved in a way similar to the argument of Theorem 4.24 of Moerdijk and Mrčun [18] as follows: For \( 1 \leq j < k \leq q_{\tilde{F}} \), we have

\[
d\Omega(Y^j, Y^k) + \frac{1}{2}[\Omega, \Omega](Y^j, Y^k)
\]

\[
= \frac{1}{2}(Y^j(\Omega(Y^k)) - Y^k(\Omega(Y^j)) - \Omega([Y^j, Y^k])) + \frac{1}{2}[\Omega(Y^j), \Omega(Y^k)]
\]

\[
= \frac{1}{2}(Y^j(\Omega(Y^k)) - Y^k(\Omega(Y^j)))
\]

\[
= 0.
\]

In the second equality, we used the equality \( \Omega([Y^j, Y^k]) = [\Omega(Y^j), \Omega(Y^k)] \) which follows from the definition of \( \Omega \). The last equality follows from the fact that the \( g \)-valued functions \( \Omega(Y^j) \) and \( \Omega(Y^k) \) are constant on \( \tilde{F} \). \( \square \)

Recall that \( \mathcal{F}_b \) denotes the foliation of \( M \) defined by the fibers of the basic fibration \( \pi_b : M \rightarrow M/\mathcal{F}_b \).

Lemma 24. Assume that the conditions (c) and (d) of Proposition 21 are satisfied. Assume that a basic closed 1-form \( \alpha \) on \((\tilde{F}, \mathcal{F}|_{\tilde{F}})\) satisfies

\[
\int_{\tilde{F}} \left( \int_{\pi_\tilde{F}} \alpha \right) \text{vol}_{\tilde{F}}(x) = 0
\]
for the flow \( \{ \phi_t \}_{t \in [0,1]} \) on \( \tilde{F} \) generated by every vector field \( X \) such that \( \omega_i(X) \) is constant on \( \tilde{F} \) for each \( i \), where \( \gamma_x \) is the orbit of \( x \) of the flow \( \{ \phi_t \}_{t \in [0,1]} \). Then we have

\[(i) \quad \alpha|_{L_b} = 0 \quad \text{for each leaf } L_b \text{ of } (\tilde{F}, \mathcal{F}_b|_{\tilde{F}}) \text{ and}
\]

\[(ii) \quad [\alpha] = 0 \quad \text{in } H^1(\tilde{F}; \mathbb{R}).\]

**Proof.** Let us show (i) in the case where \( L_b \) is the leaf \( F_b \) of \( (\tilde{F}, \mathcal{F}_b|_{\tilde{F}}) \) which contains \( x_0 \). The proof of the general case is similar.

Here \( (\tilde{F}, \mathcal{F}|_{\tilde{F}}) \) is a Lie foliation by Lemma 23 (ii). We take a connected Lie group \( G \) so that \( (\tilde{F}, \mathcal{F}|_{\tilde{F}}) \) is a \( G \)-Lie foliation. We can assume the simply connectedness of \( G \) as noted in the second paragraph of Section 3.

Let \( p^\text{univ}_F : \tilde{F}^\text{univ} \rightarrow \tilde{F} \) be the universal covering of \( \tilde{F} \). Fix a point \( x^\text{univ}_0 \) in the fiber over \( x_0 \). Let \( \tilde{F} \rightarrow G \) be the developing map of the Lie foliation \( (\tilde{F}, \mathcal{F}|_{\tilde{F}}) \) which maps \( x^\text{univ}_0 \) to the unit element \( e \) of \( G \). Let \( \text{hol} \) be the holonomy homomorphism \( \pi_1(\tilde{F}, x_0) \rightarrow G \) of the Lie foliation \( (\tilde{F}, \mathcal{F}|_{\tilde{F}}) \). By (I) of Section 3 every basic 1-form on \( (\tilde{F}^\text{univ}, (p^\text{univ}_F)^*(\mathcal{F}|_{\tilde{F}})) \) is the pullback of a 1-form on \( G \) by \( \text{dev} \). Hence there exists a 1-form \( \overline{\alpha} \) on \( G \) such that

\[
(p^\text{univ}_F)^* \alpha = \text{dev}^* \overline{\alpha}.
\]

By (II) of Section 3 and the invariance of \( (p^\text{univ}_F)^* \alpha \) under the \( \pi_1(\tilde{F}, x_0) \)-action on \( \tilde{F}^\text{univ} \), we have

\[
R^*_\text{hol}(\gamma) \overline{\alpha} = \overline{\alpha}
\]

for \( \gamma \) in \( \pi_1(\tilde{F}, x_0) \), where \( R^*_\text{hol}(\gamma) : G \rightarrow G \) is the right multiplication map by \( \text{hol}(\gamma) \). Let \( H \) be the closure of the image of \( \text{hol} \) in \( G \). Note that \( H \) is a proper subgroup of \( G \) if the leaves of \( (\tilde{F}, \mathcal{F}|_{\tilde{F}}) \) are not dense by (II) in Section 3. It follows from (32) that

\[
R^*_0 \overline{\alpha} = \overline{\alpha}
\]

for every \( g \) in \( H \).

In the sequel, for a path \( \gamma \) in \( \tilde{F} \), we denote a lift of \( \gamma \) to \( \tilde{F}^\text{univ} \) by \( \gamma^\text{univ} \). By (33), we have

\[
\int_{\gamma} \alpha = \int_{\gamma^\text{univ}} (p^\text{univ}_F)^* \alpha = \int_{\gamma^\text{univ}} \text{dev}^* \overline{\alpha} = \int_{\text{dev}^*_\gamma \gamma^\text{univ}} \overline{\alpha}.
\]

Let \( \gamma \) be a closed path on \( \tilde{F} \) whose endpoints are \( x_0 \). We denote the element of \( \pi_1(\tilde{F}, x_0) \) represented by \( \gamma \) by the same symbol \( \gamma \). Let \( X_\gamma \) be the left invariant vector field on \( G \) such that \( \exp X_\gamma = \text{hol}(\gamma) \). Let \( X^\text{univ}_\gamma \) be a lift of \( X_\gamma \) to \( \tilde{F}^\text{univ} \) which is invariant by the action of \( \text{hol}(\pi_1(\tilde{F}, x_0)) \). Let \( X_\gamma \) be the vector field on \( \tilde{F} \) whose lift to \( \tilde{F}^\text{univ} \) is \( X^\text{univ}_\gamma \). Let \( \gamma_x \) be the orbit of \( x \) in \( \tilde{F} \) of the flow \( \{ \phi_t \}_{t \in [0,1]} \) generated by \( X_\gamma \). It follows that \( \text{dev}^*_\gamma \gamma^\text{univ}_x \) is an orbit of the flow generated by \( X_\gamma \) from the definition of \( X_\gamma \) and \( \gamma_x \). Hence we have

\[
\text{dev}^*_\gamma \gamma^\text{univ}_x(t) = \text{dev}^*_\gamma \gamma^\text{univ}_x(0) \cdot \exp(i X_\gamma).
\]
We take the lifts $\gamma^\text{univ}$ and $\gamma^\text{univ}_{x_0}$ of $\gamma$ and $\gamma_{x_0}$ to $\bar{F}^\text{univ}$ so that $\gamma^\text{univ}(0) = \gamma^\text{univ}_{x_0}(0) = x^\text{univ}_0$, respectively. Then, by (36) and (35), we have
\begin{align}
(36) & \quad \text{dev}_* \gamma^\text{univ}_{x_0}(0) = e = \text{dev}_* \gamma^\text{univ}(0), \\
(37) & \quad \text{dev}_* \gamma^\text{univ}_{x_0}(1) = \text{hol}(\gamma) = \text{dev}_* \gamma^\text{univ}(1).
\end{align}
Since $G$ is simply connected, (34), (36), (37) and the Stokes theorem imply
\begin{align}
(38) & \quad \int_\gamma \alpha = \int_{\text{dev}_* \gamma^\text{univ}} \overline{\alpha} = \int_{\text{dev}_* \gamma^\text{univ}_{x_0}} \overline{\alpha} = \int_{\gamma_{x_0}} \alpha.
\end{align}
It follows from (38) and dev$(\gamma^\text{univ}_{x_0}(0)) = e$ that
\begin{align}
(39) & \quad \text{dev}_* \gamma^\text{univ}_{x_0} = (R_{\text{dev}(\gamma^\text{univ}(0))} \circ \text{dev}(\gamma^\text{univ}(0))^{-1})_* \text{dev}_* \gamma^\text{univ}_{x_0} = (R_{\text{dev}(\gamma^\text{univ}(0))})_* \text{dev}_* \gamma^\text{univ}_{x_0} \circ (R_{\text{dev}(\gamma^\text{univ}(0))})_* \text{dev}_* \gamma^\text{univ}_{x_0}.
\end{align}
If $\gamma$ and $x$ are contained in $F_b$, then we can take $\gamma^\text{univ}_{x_0}$ so that dev$(\gamma^\text{univ}(0))$ is contained in $H$. By using (33), (39), (33) and (34), in this order, we have
\begin{align}
(40) & \quad \int_\gamma \alpha = \int_{\text{dev}_* \gamma^\text{univ}} \overline{\alpha} = \int_{(R_{\text{dev}(\gamma^\text{univ}(0))})_* \text{dev}_* \gamma^\text{univ}_{x_0}} \overline{\alpha} = \int_{\text{dev}_* \gamma^\text{univ}_{x_0}} \overline{\alpha} = \int_{\gamma_{x_0}} \alpha.
\end{align}
Since $X_\alpha$ satisfies the condition of $X$ in the statement of Lemma 24, we have
\begin{align}
(41) & \quad \int_{\bar{F}} (\int_{\gamma_x} \alpha) \text{vol}_{\bar{F}}(x) = 0
\end{align}
by the assumption.

By (33), (34) and (31), we have
\begin{align}
(42) & \quad \int_{\gamma} \alpha = 0.
\end{align}
Then $\alpha|_{F_b}$ is exact. Hence there exists a basic function $h$ on $(F_b, \mathcal{F}|_{F_b})$ such that $dh = \alpha|_{F_b}$. But since the leaves of $(F_b, \mathcal{F}|_{F_b})$ are dense, $h$ is constant. Then we have $\alpha = dh = 0$, which completes the proof of (i).

In the following five paragraphs, we will show
\begin{align}
(43) & \quad \int_{\gamma_x} \alpha = \int_{\gamma_{x_0}} \alpha
\end{align}
for every point $x$ on $\bar{F}$.

Let us show that $[\alpha]$ in $H^1(\bar{F}; \mathbb{R})$ is contained in the image of $(\pi_b|_{\bar{F}})^* : H^1(\bar{F}/F_b; \mathbb{R}) \to H^1(\bar{F}; \mathbb{R})$, where $\pi_b : M \to M/\mathcal{F}_b$ is the basic fibration of $(M, \mathcal{F})$. Since $\alpha$ is basic with respect to $\mathcal{F}$, we have $\phi^* \alpha = \alpha$ for a diffeomorphism $\phi$ which maps each leaf of $\mathcal{F}$ to itself. Each leaf $L$ of $\mathcal{F}$ is dense in the leaf $L_b$ of $\mathcal{F}|_{\bar{F}}$ which contains $L$. Hence the orbits of the group of diffeomorphisms which map each leaf of $\mathcal{F}$ to itself is dense in $L_b$. So we have $(L_b \alpha)_x = 0$ for every point $x$ on $M$ and every $Y$ in $T_x M$ tangent to $L_b$. Since $\alpha|_{L_b}$ is zero by (i), $\alpha$ is basic with respect to $\mathcal{F}_b$. Thus $[\alpha]$ in $H^1(\bar{F}; \mathbb{R})$ is contained in $(\pi_b|_{\bar{F}})^* (H^1(\bar{F}/F_b; \mathbb{R}))$ in $H^1(\bar{F}; \mathbb{R})$.

The path $\gamma_x$ may not be closed in general. But let us show that $(\pi_b)_* \gamma_x$ is closed, where $\pi_b : M \to M/\mathcal{F}_b$ is the basic fibration of $(M, \mathcal{F})$. Let $H$ be the Lie subgroup of $G$ defined by the closure of $\text{hol}(\pi_1(\bar{F}, x_0))$. The structural Lie algebra of the Lie foliation $(F_b, \mathcal{F}|_{F_b})$ is Lie$(H)$, and hence $\dim H = \text{cod}(F_b, \mathcal{F}|_{F_b})$. By the equivariance of the developing map in (30), the map dev : $\bar{F}^\text{univ} \to G$ induces a map $\text{dev}_{G/H} : \bar{F} \to G/H$. Furthermore, dev$_{G/H}$ induces a map $\varpi : \bar{F}/\mathcal{F}_b \to G/H$. 

Since \( \varpi \) is a submersion between two manifolds of the same dimension, \( \varpi \) is a covering map. Since \( \varpi \) is injective as easily confirmed, \( \varpi \) is a diffeomorphism.

Let \( X_b \) be a vector field on \( \bar{F}/\mathcal{F}_b \) induced from \( X_\gamma \). Let \( \bar{X}_{G/H} \) be a vector field on \( G/H \) induced from a vector field \( \bar{X}_\gamma \) on \( G \). By definition of \( X_\gamma \) and \( \bar{X}_\gamma \), we have

\[
(44) \quad \varpi_* \bar{X}_{G/H} = X_b.
\]

Recall that \( \gamma_x \) is the orbit of \( x \) of the flow \( \{ \phi_t \}_{0 \leq t \leq 1} \) generated by \( X_\gamma \) from time zero to time one. Thus \( (\pi_b)_* \gamma_x \) is the orbit of \( x \) of the flow generated by \( X_b \) from time zero to time one. By \((44)\), \( \varpi \) maps an orbit of the flow generated by \( X_b \) from time zero to time one to an orbit of the flow on \( G/H \) generated by the vector field \( \bar{X}_{G/H} \) from time zero to time one. Here the time one map of the flow generated by \( \bar{X}_{G/H} \) is the identity, because this map is induced by the time one map of the flow on \( G \) generated by \( X_\gamma \), which is the right multiplication map by an element of \( \text{hol}(\pi_1(\bar{F}, x_0)) \) by definition of \( \bar{X}_\gamma \). Hence \((\pi_b)_* \gamma_x \) is a closed path on \( \bar{F}/\mathcal{F}_b \) for each \( x \).

The homology class determined by \((\pi_b)_* \gamma_x \) in \( \bar{F}/\mathcal{F}_b \) is independent of \( x \). This is because \( \gamma_x \) and \( \gamma_y \) are bounded by a 1-parameter family of closed paths on \( \bar{F}/\mathcal{F}_b \) of the form \( \{ \gamma_{l(\alpha)} \}_{0 \leq l \leq 1} \), where \( l \) is a path on \( F \) such that \( l(0) = x \) and \( l(1) = y \) for every two points \( x \) and \( y \) in \( \bar{F}/\mathcal{F}_b \).

Thus, by the argument in the previous three paragraphs, \([\alpha]\) is contained in \((\pi_0)^*(H^1(\bar{F}/\mathcal{F}_b; \mathbb{R}))\), and \((\pi_b)_* \gamma_x \) determines the same homology class of \( \bar{F}/\mathcal{F}_b \) for every \( x \). Hence \((45)\) is proved.

By \((38)\), \((41)\) and \((43)\), we have

\[
(45) \quad \int_\gamma \alpha = 0.
\]

Hence (ii) is proved. \( \square \)

5.4. Two lemmas on a fiber bundle over \( S^1 \) with fiberwise Lie foliations.

We will show two lemmas to use in the next section. Note that \((\bar{F}, \mathcal{F}_b|_{\bar{F}})\) is transversely orientable by the assumption of the orientability of both of \( \bar{F} \) and the basic fibration \( \pi_b: M \to M/\mathcal{F}_b \) of \((M, \mathcal{F})\).

Lemma 25. Assume that the conditions (c) and (d) of Proposition 21 are satisfied.

Let \( \gamma: S^1 \to M \) be a smooth embedding in \( M \). Assume that \( \gamma \) is transverse to the fibers of \( \pi_{\bar{F}} \), and that \( \pi_{\bar{F}} \circ \gamma \) is an embedding. Let \( M' = \pi_{\bar{F}}^{-1}(\pi_{\bar{F}}(S^1)) \). Then there exists a flat connection \( \nabla \) on \( \pi_{\bar{F}}|_{M'} \) which satisfies the following four conditions:

\begin{enumerate}
  \item[(A):] The holonomy map \( f : \bar{F} \to \bar{F} \) of \( \nabla \) preserves the foliation \( \mathcal{F}_b|_{\bar{F}} \).
  \item[(B):] The holonomy map \( f \) of \( \nabla \) preserves a transverse volume form \( \mu_{\bar{F}/\mathcal{F}_b} \) of \((\bar{F}, \mathcal{F}_b|_{\bar{F}})\).
  \item[(C):] We denote the inverse map \( \pi_{\bar{F}} \circ \gamma(S^1) \to S^1 \) of \( \pi_{\bar{F}} \circ \gamma \) by \( \varphi \). We define a section \( \gamma_1 \) of \( \pi_{\bar{F}}|_{M'} \) by \( \gamma_1 = \gamma \circ \varphi \). Then \( \gamma_1 \) is a section parallel to \( \nabla \).
  \item[(D):] There exists a vector field \( Z_{\nabla} \) such that the orbits of the flow generated by \( Z_{\nabla} \) is parallel to \( \nabla \) and the restriction of \( \omega_i(Z_{\nabla}) \) to each fiber of \( \pi_{\bar{F}} \) is constant.
\end{enumerate}
there exists a vector field \( Y \) tangent to \( F \) defined on \( \gamma_1(S^1) \) and functions \( h_1, h_2, \cdots, h_q \) on \( S^1 \) such that

\[
(D\gamma_1)_t \left( \frac{\partial}{\partial t} \right) = Y_{\gamma_1(t)} + \sum_{j=1}^q h_j(t)(\dot{X}^j)_{\gamma_1(t)},
\]

where \( (D\gamma_1)_t \) is the differential map of \( \gamma_1 \) at a point \( t \). Let \( Y' \) be a vector field on \( M' \) which is tangent to \( F \) and whose restriction to \( \gamma_1(S^1) \) is equal to \( Y \). We define a vector field \( Z_{\nabla} \) on \( M' \) by

\[
Z_{\nabla} = Y' + \sum_{j=1}^q ((\pi_{\nabla}|_{M'})^*h_j)\dot{X}^j.
\]

The restriction of \( Z_{\nabla} \) to \( \gamma_1(S^1) \) is equal to the tangent vectors of \( \gamma_1 \) by \( (46) \). \( Z_{\nabla} \) is basic with respect to \( F \) and transverse to the fibers of \( \pi_{\nabla} \). We define a connection \( \nabla' \) on \( \pi_{\nabla} \) by the line field tangent to \( Z_{\nabla} \) at each point on \( M' \). It is trivial that \( \nabla' \) is flat, because every connection on a fiber bundle over \( S^1 \) is flat.

Let us show that \( \nabla' \) satisfies the conditions (A), (B), (C) and (D). Here, \( \hat{\nabla} \) is basic with respect to \( F \) and \( \tilde{F} \), \( \tilde{F} \) is the closure of the leaves of \( \tilde{F} \). Since the leaves of \( \tilde{F} \) are the closures of the leaves of \( F \), the flow generated by \( Z_{\nabla} \) maps the leaves of \( \tilde{F} \) to the leaves of \( F \). Hence \( \tilde{F} \) satisfies the condition (A). By the conditions (c), (d) of Proposition \( 21 \) and Lemma \( 23 \) (ii), \( (\tilde{F}, F|_{\tilde{F}}) \) is a Lie foliation. Let \( G \) be a connected Lie group such that \( (\tilde{F}, F|_{\tilde{F}}) \) is a G-Lie foliation. We can assume the simply connectedness of \( G \) as noted in the second paragraph of Section \( 3 \). Let \( H \) be the Lie subgroup of \( G \) such that \( \text{Lie}(H) \) is the structural Lie algebra of the Lie foliation \( (F_b, F|_{F_b}) \). We denote the universal cover of \( \tilde{F} \) by

\[
p_{\tilde{F}}^{\text{univ}} : \tilde{F}^{\text{univ}} \rightarrow \tilde{F}.
\]

We recall the notation

\[
q_{\tilde{F}} = \text{cod}(\tilde{F}, F|_{\tilde{F}})
\]

and let

\[
q_{b, \tilde{F}} = \text{cod}(\tilde{F}, F_b|_{\tilde{F}}).
\]

Note that \( \dim G = q_{\tilde{F}} \) and the codimension of \( H \) in \( G \) is equal to \( q_{b, \tilde{F}} \). We regard \( (\text{Lie}(G)/\text{Lie}(H))^* \) as a subset of \( \text{Lie}(G)^* \) consisting of the elements whose restriction to \( \text{Lie}(H) \) is 0. Fix a basis \( \{ \beta_1, \beta_2, \cdots, \beta_{q_{\tilde{F}}} \} \) of \( \text{Lie}(G)^* \) so that \( \{ \beta_1, \beta_2, \cdots, \beta_{q_{b, \tilde{F}}} \} \) is a basis of \( (\text{Lie}(G)/\text{Lie}(H))^* \). Note that \( \text{dev}_G^* \beta_j \) is \( \pi_1 \tilde{F} \)-invariant. Let \( \beta_j \) be the
1-form on $\tilde{F}$ induced by the $\pi_1\tilde{F}$-invariant 1-form $\text{dev}^\gamma_i\beta_j$ on $\tilde{F}^{\text{univ}}$ for $1 \leq j \leq q_{\tilde{F}}$. Then the restriction of $\beta_j$ to each leaf of $\tilde{F}$ is zero for $1 \leq j \leq q_{\tilde{F}}$. Note that the Maurer-Cartan form of $(\tilde{F}, \mathcal{F}_b|_{\tilde{F}})$ is given by the equation (29). Hence, by (V) of Section 3, we can write
\begin{equation}
\beta_j = \sum_{i=1}^{q_{\tilde{F}}} b^i_j \omega_i|_{\tilde{F}}
\end{equation}
for each $j$ for some constants $b^i_j$, $1 \leq i \leq q_{\tilde{F}}$.

We define a transverse volume form $\mu_{\tilde{F}/\mathcal{F}_b}$ on $(\tilde{F}, \mathcal{F}_b|_{\tilde{F}})$ by
\begin{equation}
\mu_{\tilde{F}/\mathcal{F}_b} = \beta_1 \wedge \beta_2 \wedge \cdots \wedge \beta_{q_{\tilde{F}}},
\end{equation}
Since $\mu_{\tilde{F}/\mathcal{F}_b}$ is closed, we have
\begin{equation}
L_{Z\nabla}\mu_{\tilde{F}/\mathcal{F}_b} = dL_{Z\nabla}\mu_{\tilde{F}/\mathcal{F}_b} = dL_{\nabla}(\beta_1 \wedge \beta_2 \wedge \cdots \wedge \beta_{q_{\tilde{F}}}).
\end{equation}
Here we recall $q_{\tilde{F}} = \text{cod}(\tilde{F}, \mathcal{F}_b|_{\tilde{F}})$. Note that $\omega_i(Z\nabla)$ is constant on $\tilde{F}$ by definition of $Z\nabla$. Then $\beta_j(Z\nabla)$ is also constant on $\tilde{F}$. We can write $d\beta_i$ as a sum of $\beta_j \wedge \beta_k$ on $M$ as
\begin{equation}
\sum_{1 \leq j < k \leq q} c_i^j \beta_j \wedge \beta_k.
\end{equation}
Then the restriction of $c_i^j$ to $\tilde{F}$ is constant by the condition (c) of Proposition 21. Then there exists a constant $C_0$ such that
\begin{equation}
d\mu_{\tilde{F}/\mathcal{F}_b} = C_0(\beta_1 \wedge \beta_2 \wedge \cdots \wedge \beta_{q_{\tilde{F}}})_x
\end{equation}
for every point $x$ on $\tilde{F}$. By (63) and (55), we have
\begin{equation}
(L_{Z\nabla}\mu_{\tilde{F}/\mathcal{F}_b})_x = C_0(\mu_{\tilde{F}/\mathcal{F}_b})_x.
\end{equation}
for every point $x$ on $\tilde{F}$. In the same way, there exists a constant $C_0^t$ such that
\begin{equation}
(L_{Z\nabla}\mu_{\tilde{F}/\mathcal{F}_b})_x = C_0^t(\mu_{\tilde{F}/\mathcal{F}_b})_x
\end{equation}
for every point $x$ on $\pi_{\tilde{F}}^{-1}(t)$ for each $t$ in $\pi_{\tilde{F}} \circ \gamma(S^1)$. By (57), $f$ satisfies
\begin{equation}
f^*\mu_{\tilde{F}/\mathcal{F}_b} = C_1\mu_{\tilde{F}/\mathcal{F}_b}
\end{equation}
for a constant $C_1$. Let $\tilde{F}/\mathcal{F}_b$ be the leaf space of $(\tilde{F}, \mathcal{F}_b|_{\tilde{F}})$. $\tilde{F}/\mathcal{F}_b$ is a closed manifold. This $\tilde{F}/\mathcal{F}_b$ is orientable by the transverse orientability of $(\tilde{F}, \mathcal{F}_b|_{\tilde{F}})$. Let $\mathcal{T}$ be the map induced by $f$ on $\tilde{F}/\mathcal{F}_b$. Since $\mu_{\tilde{F}/\mathcal{F}_b}$ is basic, it is a pull back of a volume form $\pi_{\tilde{F}/\mathcal{F}_b}$ on $\tilde{F}/\mathcal{F}_b$. We have
\begin{equation}
\mathcal{T}^*\pi_{\tilde{F}/\mathcal{F}_b} = C_1\pi_{\tilde{F}/\mathcal{F}_b}
\end{equation}
Hence $C_1$ is equal to 1, because $C_1$ is equal to the mapping degree of a diffeomorphism $\mathcal{T}$: $\tilde{F}/\mathcal{F}_b \rightarrow \tilde{F}/\mathcal{F}_b$. It follows from (58) that $\nabla$ satisfies the condition (B).

A section of $C^\infty(\wedge^k T^*\mathcal{F})$ is called a leafwise $k$-form on $(M, \mathcal{F})$. If $k = \dim \mathcal{F}$, a leafwise $k$-form is called a leafwise volume form on $(M, \mathcal{F})$. The wedge product induces a natural operation $C^\infty(\wedge^k T^*\mathcal{F}) \otimes C^\infty(\wedge^q (TM/T\mathcal{F})) \rightarrow C^\infty(\wedge^{q+k} T^*M)$. 

Lemma 26. Let \( \gamma : S^1 \to M \) be a smooth embedding in \( M \). Assume that \( \gamma \) is transverse to the fibers of \( \pi \), and that \( \pi \circ \gamma \) is an embedding. Let \( M' = \pi^{-1}(\pi(\gamma(S^1))) \). Fix a fiber \( \tilde{F} \) of \( \pi|_{M'} \) and a point \( x_0 \) on \( \tilde{F} \). Let \( \nabla \) be a flat connection on \( \pi|_{M'} \). Let \( f : \tilde{F} \to \tilde{F} \) be the holonomy of the flat connection \( \nabla \) with respect to the path \( \pi \circ \gamma \). For \( x \) on \( \tilde{F} \), let \( \gamma_x \) be the lift of the path \( \pi \circ \gamma \) to \( M' \) such that \( \gamma_x(0) = x \) and \( \gamma_x \) is parallel to \( \nabla \). Let \( \alpha \) be a closed 1-form on \( M \) such that \( [\alpha]_{\tilde{F}} = 0 \) in \( H^1(\tilde{F}; \mathbb{R}) \) and \( \alpha|_{L_b} = 0 \) on each leaf \( L_b \) of \( (\tilde{F}, \mathcal{F}_b|_{\tilde{F}}) \).

We assume that \( \nabla \) satisfies the conditions (A), (B) and (C) in the statement of Lemma 25. Let \( \eta_{F_b} \) be a leafwise volume form on \( (\tilde{F}, \mathcal{F}_b|_{\tilde{F}}) \) such that \( \eta_{F_b} \wedge \mu_{\tilde{F}/F_b} = \text{vol}_{\tilde{F}} \).

Since each leaf \( L_b \) of \( \mathcal{F}_b|_{\tilde{F}} \) is compact and oriented by the assumption, \( f \) maps the fundamental class of \( L_b \) to the fundamental class of \( f(L_b) \). Then we have a leafwise \( (\dim \mathcal{F}_b - 1) \)-form \( \sigma \) on \( (\tilde{F}, \mathcal{F}_b|_{\tilde{F}}) \) such that \( d\sigma = f^* \eta_{F_b} - \eta_{F_b} \). By adding a closed \( (\dim \mathcal{F}_b - 1) \)-form supported on an open neighborhood of \( x_0 \) to \( \sigma \), we can modify \( \sigma \) so that \( \sigma_{x_0} = 0 \) and \( d\sigma = f^* \eta_{F_b} - \eta_{F_b} \) are satisfied. Since \( \eta_{F_b} \) is a leafwise volume form on \( (\tilde{F}, \mathcal{F}_b|_{\tilde{F}}) \), there exists a vector field \( Y \) on \( \tilde{F} \) tangent to leaves of \( \tilde{F} \) such that \( -i_Y \eta_{F_b} = \sigma \). Let \( \{ \phi_s \}_{s \in \mathbb{R}} \) be the flow generated by \( Y \). Let \( \eta_s = \eta_{F_b} + s \sigma \)

We have

\[
\frac{d(\phi_s^* \eta_{F_b})}{ds} = \phi_s^* \left( L_Y \eta_s + \frac{d\eta_s}{ds} \right) = \phi_s^* d(i_Y \eta_{F_b} + \sigma) = 0.
\]

Hence we have

\[
\phi_s^* f^* \eta_{F_b} = \phi_s^* \eta_0 = \eta_0 = \eta_{F_b}.
\]

Thus \( f \circ \phi_1 \) preserves \( \eta_{F_b} \). Here, \( \phi_s \) maps each leaf of \( \tilde{F} \) to itself, because \( Y \) is tangent to leaves of \( \tilde{F} \). Then clearly \( \phi_1 \) preserves the transverse volume form \( \mu_{\tilde{F}/F_b} \). Since \( f \) preserves \( \mu_{\tilde{F}/F_b} \) by the assumption, by (61) and (63), we have

\[
(f \circ \phi_1)^* \mu_{\tilde{F}} = (f \circ \phi_1)^* \eta_{F_b} \wedge (f \circ \phi_1)^* \mu_{\tilde{F}/F_b} = \eta_{F_b} \wedge \mu_{\tilde{F}/F_b} = \text{vol}_{\tilde{F}}.
\]

Hence \( f \circ \phi_1 \) preserves \( \text{vol}_{\tilde{F}} \). Since \( \sigma_{x_0} = 0 \), we have \( Y_{x_0} = 0 \). This implies that \( \phi_s \) fixes \( x_0 \).

Using \( \{ \phi_s \}_{s \in [0,1]} \), we can construct a smooth family \( \{ \nabla_s \}_{s \in [0,1]} \) of flat connections on \( \pi|_{M'} \) such that \( \nabla_0 = \nabla \) and the holonomy of \( \nabla_s \) with respect to \( \pi \circ \gamma \) is \( f \circ \phi_s \). Since each \( \phi_s \) fixes \( x_0 \), we can take \( \{ \nabla_s \}_{s \in [0,1]} \) so that

\[
\gamma^s = \gamma^s_{x_0}.
\]
for $0 \leq s \leq 1$. For $x \in \bar{F}$, let $\gamma_s^x$ be the lift of the path $\pi_{\bar{F}} \circ \gamma$ to $M$ such that $\gamma_s(0) = x$ and $\gamma_s$ is parallel to $\nabla_1$. We take a function $h$ on $\bar{F}$ so that $dh = \alpha|_{\bar{F}}$. For each point $x$ in $\bar{F}$, we have
\begin{equation}
\int_{\gamma_s^0} \alpha + (h(\phi_1 \circ f(x)) - h(f(x))) - \int_{\gamma_s^1} \alpha = 0
\end{equation}
by the Stokes’ theorem. By the assumption on $\alpha$, the restriction of $h$ to each leaf of $F_b|_{\bar{F}}$ is constant. Since $\phi_1 \circ f$ maps each leaf of $\bar{F}$ to itself, we have $h(\phi_1 \circ f(x)) - h(f(x)) = 0$. Hence, by (66), we have
\begin{equation}
\int_{\gamma_s^0} \alpha - \int_{\gamma_s^1} \alpha = 0
\end{equation}
for each point $x$ on $\bar{F}$. Then we have
\begin{equation}
\int_{\bar{F}} \left( \int_{\gamma_s^0} \alpha \right) \text{vol}_{\bar{F}} - \int_{\bar{F}} \left( \int_{\gamma_s^1} \alpha \right) \text{vol}_{\bar{F}} = \int_{\bar{F}} \left( \int_{\gamma_s^0} \alpha - \int_{\gamma_s^1} \alpha \right) \text{vol}_{\bar{F}} = 0.
\end{equation}
For each point $x$ on $\bar{F}$, we have
\begin{equation}
(h(x) - h(x_0)) + \int_{\gamma_s^1} \alpha + (h(f \circ \phi_1(x_0)) - h(f(x))) - \int_{\gamma_s^1} \alpha = 0
\end{equation}
by the Stokes’ theorem. We get
\begin{equation}
\int_{\bar{F}} \left( \int_{\gamma_s^1} \alpha \right) \text{vol}_{\bar{F}} - \left( \int_{\bar{F}} \text{vol}_{\bar{F}} \right) \left( \int_{\gamma_s^1} \alpha \right) = 0
\end{equation}
as follows:
\begin{align*}
&\int_{\bar{F}} \left( \int_{\gamma_s^1} \alpha \right) \text{vol}_{\bar{F}} - \left( \int_{\bar{F}} \text{vol}_{\bar{F}} \right) \left( \int_{\gamma_s^1} \alpha \right) \\
&= \int_{\bar{F}} \left( \int_{\gamma_s^1} \alpha \right) \text{vol}_{\bar{F}} - \left( \int_{\bar{F}} \text{vol}_{\bar{F}} \right) \left( \int_{\gamma_s^1} \alpha \right) \\
&= \int_{\bar{F}} \left( \int_{\gamma_s^1} \alpha \right) \text{vol}_{\bar{F}} - \int_{\bar{F}} \left( \int_{\gamma_s^1} \alpha \right) \text{vol}_{\bar{F}} \\
&= \int_{\bar{F}} \left( \int_{\gamma_s^1} \alpha \right) \text{vol}_{\bar{F}} \\
&= \int_{\bar{F}} \left( (h(x) - h(x_0)) - (h(f \circ \phi_1(x_0)) - h(f \circ \phi_1(x))) \right) \text{vol}_{\bar{F}} \\
&= - \int_{\bar{F}} (h(x) - h(x_0)) \text{vol}_{\bar{F}} + \int_{\bar{F}} (h(x) - h(x_0)) \phi_1^* \text{vol}_{\bar{F}} \\
&= 0,
\end{align*}
where we used (65) in the first equality, (69) in the fourth equality and $\phi_1^* \text{vol}_{\bar{F}} = \text{vol}_{\bar{F}}$ in the last equality. The equation (60) follows from (68) and (70).

5.5. $\xi(F) = [\tilde{\kappa}_b]$ on $M$. We will show a lemma which will be used to complete the proof of Proposition 21 (ii). Note that $\alpha$ will be considered to be $\xi(F) - [\tilde{\kappa}_b]$ in the application in Section 5.6.

**Lemma 27.** Assume that the conditions (a), (b), (c) and (d) of Proposition 21 are satisfied. Assume that $\gamma_0$ in $\pi_1(M, x_0)$ satisfies the following conditions: $\gamma_0$ is represented by a smooth path $l'_0 : [0, 1] \rightarrow M$ which factors a smooth embedding $l_0 : S^1 \rightarrow M$ and is transverse to the fibers of $\pi_{\bar{F}}$, and $\pi_{\bar{F}} \circ l_0$ is a smooth embedding. Let $\alpha$ be a closed basic 1-form on $(M, F)$ which satisfies the following conditions:
(i) $\alpha|_{L_b} = 0$ for each leaf $L_b$ of $(\bar{F}, F_b|_{\bar{F}})$. 

(ii) $\alpha|_{\tilde{F}}$ is exact.

(iii) For any submanifold $M'$ of $M$ which is a union of fibers of $\pi_{\tilde{F}}$,

$$\int_{M'} \left( \int_{\gamma_x} \alpha \right) \text{vol}_{M'}(x) = 0$$

is satisfied for the flow $\{\phi_t\}_{t \in [0,1]}$ generated by every vector field $X$ such that $\omega_i(X)$ is constant on each fiber of $\pi_{\tilde{F}}$ for each $i$, where $\gamma_x$ is the orbit of $x$ of the flow $\{\phi_t\}_{t \in [0,1]}$.

Then we have

$$\int_{\gamma_0} \alpha = 0.$$

**Proof.** Let

$$K = \pi_{\tilde{F}} \circ l_0(S^1), \quad M' = \pi_{\tilde{F}}^{-1}(K).$$

$M'$ is a submanifold of $M$ which is a union of fibers of $\pi_{\tilde{F}}$ by the assumption on $\gamma_0$.

By the condition (a), we have

$$\int_{M'} \left( \int_{\gamma_x} \alpha \right) \text{vol}_{M'}(x) = \int_K \left( \int_{\pi_{\tilde{F}}} \left( \int_{\gamma_x} \alpha \right) \text{vol}_{\pi_{\tilde{F}}}(x) \right) \text{vol}_K.$$

By the conditions (c), (d) and Lemma 25, there exists a flat connection $\nabla$ on the fiber bundle $M' \to K$ which satisfies the conditions (A), (B), (C) and (D) in the statement of Lemma 25. By condition (D) and the assumption (iii), we have

$$\int_{M'} \left( \int_{\gamma_x} \alpha \right) \text{vol}_{M'}(x) = 0.$$

Since the assumptions of Lemma 26 are satisfied by the conditions (A), (B) and (C), we have

$$\int_{\pi_{\tilde{F}}^{-1}(t)} \left( \int_{\gamma_x} \alpha \right) \text{vol}_{\pi_{\tilde{F}}^{-1}(t)} = \int_{\pi_{\tilde{F}}^{-1}(t)} \text{vol}_{\pi_{\tilde{F}}^{-1}(t)} \left( \int_{\gamma_x} \alpha \right)$$

for each $t$ in $K$ by Lemma 26. By condition (b) and Lemma 26, the volume of fibers of $\pi_{\tilde{F}}$ is constant. By (74), (75) and (76), we have

$$\int_{\tau_{\gamma_0}} \alpha = 0.$$

Hence Lemma 27 is proved. $\square$

5.6. **Proof of Proposition 21 (ii).** By the homotopy exact sequence of the fiber bundle $\pi_{\tilde{F}}$, we have an exact sequence

$$\pi_2(M/\tilde{F}, \pi_{\tilde{F}}(x_0)) \to \pi_1(\tilde{F}, x_0) \to \pi_1(M, x_0) \to \pi_1(M/\tilde{F}, \pi_{\tilde{F}}(x_0)) \to 0.$$

By Lemmas 22 and 24, we have $\kappa_b|_{L_b} - \tilde{\kappa}_b|_{L_b}$ for every leaf $L_b$ of $(\tilde{F}, \mathcal{F}_b|_{\tilde{F}})$ and $[\kappa_b|_{\tilde{F}}] - [\tilde{\kappa}_b|_{\tilde{F}}] = 0$. This implies that $[\kappa_b] - [\tilde{\kappa}_b]$ vanishes on the image of $i$. Then Lemma 27 implies $\int_{\gamma} (\kappa_b - \tilde{\kappa}_b) = 0$ for $\gamma$ in $\pi_1(M, x_0)$ such that

- $\gamma$ is transverse to the fibers of $\pi_{\tilde{F}}$ and
- $\pi_{\tilde{F}} \circ \gamma$ is an embedding.
Note that $\pi_1(M/\tilde{F}, \pi_\tilde{F}(x_0))$ is generated by the loops of the form $(\pi_\tilde{F})$, $\gamma$ where $\gamma$ runs on all of the closed paths satisfying these two conditions. Hence we have $[\kappa_0] = [\tilde{\kappa}_0]$ in $H^1(M; \mathbb{R})$.

6. Continuity of the Álvarez Classes

We will show Theorem 1 for smooth families of orientable transversely parallelizable foliations using Proposition 21. We will use the notation of Definition 12 (ii).

6.1. A family version of the Molino theory. Let $U$ be a connected open subset in $\mathbb{R}^4$ which contains 0. Let $M$ be a closed manifold, and $\{F_t\}_{t \in U}$ be a smooth family of orientable transversely parallelizable foliations of $M$ over $U$ given by a smooth foliation $F_{\text{amb}}$ of $M \times U$. We define a distribution $D$ on $M \times U$ by

$$D_{(x,t)} = \{v \in T_{(x,t)}(M \times U) | vf(x,t) = 0, \forall f \in C^\infty_b(M \times U, F_{\text{amb}})\},$$

where $C^\infty_b(M \times U, F_{\text{amb}})$ is the space of basic functions on $(M \times U, F_{\text{amb}})$. By the standard argument of the Molino theory on $D$, we shall obtain the following properties of $D$ similar to the properties of the basic foliation of transversely parallelizable foliations:

Lemma 28. (i) $(M \times U, F_{\text{amb}})$ is fiberwise transitive, that is, for each two points $(x,t)$ and $(y,t)$ in $M \times U$ with the same second coordinates, there exists a diffeomorphism $f$ of $M \times U$ which preserves $F_{\text{amb}}$ and satisfies $f(x) = y$.

(ii) The dimension of $D_{(x,t)}$ is independent of $x$.

(iii) $D_{M \times \{t\}}$ is integrable, and we have a foliation $\mathcal{D}^t$ of $M \times \{t\}$ defined by $D|_{M \times \{t\}}$.

(iv) The leaf space $(M \times \{t\})/\mathcal{D}^t$ is a closed manifold and the canonical projection $M \times \{t\} \to (M \times \{t\})/\mathcal{D}^t$ is a smooth fiber bundle with compact fibers for each $t$.

Proof. Fix $t_0$ on $U$. Let $X_{\text{amb}}^i$, be a vector field on $M \times U$ which is projected to $X^i$ by the canonical projection $C^\infty(TM) \to C^\infty(TM/T\mathcal{F})$. By the compactness of $M$, for a relative compact open neighborhood $U'$ of $t_0$ in $U$, each $X_{\text{amb}}^i$ generates a flow $\{\phi_t^i\}_{s \in \mathbb{R}}$ on $M \times U'$. By the proof of Theorem 4.8 of Moerdijk and Mrčun [15], for each two points $(x,t_0)$ and $(y,t_0)$ in $M \times \{t_0\}$, there exists a diffeomorphism $f$ of $M \times \{t_0\}$ which is a composition of $\phi_{t_0}^i|_{M \times \{t_0\}}$, $\phi_{t_0}^2|_{M \times \{t_0\}}$, $\cdots$, $\phi_{t_0}^q|_{M \times \{t_0\}}$ for some $s_i$ and diffeomorphisms of $M \times \{t_0\}$ preserving each leaf of $\mathcal{F}^{t_0}$ whose supports are contained in a foliated chart of $\mathcal{F}^{t_0}$. Since $X_{\text{amb}}^i$ is basic with respect to $(M \times U', F_{\text{amb}})$, $\phi_{t_0}^i$ preserves $F_{\text{amb}}$. We can extend diffeomorphisms of $M \times \{t_0\}$ which preserve each leaf of $\mathcal{F}^{t_0}$ and whose supports are contained in a foliated chart of $\mathcal{F}^{t_0}$ to diffeomorphisms of $M \times U'$ preserving each leaf of $F_{\text{amb}}$. Then $f$ extends to a diffeomorphism of $M \times U'$ preserving $F_{\text{amb}}$ as a composite of $\phi_{t_0}^1$, $\phi_{t_0}^2$, $\cdots$, $\phi_{t_0}^q$ and diffeomorphisms of $M \times U'$ preserving each leaf of $F_{\text{amb}}$. This proves (i).

Properties (ii), (iii) and (iv) follow from (i) and the proof of Theorem 4.3 of Moerdijk and Mrčun [18]. We write down the proof for the sake of completeness. Since $D|_{M \times U'}$ is preserved by a diffeomorphism of $M \times U'$ preserving $F_{\text{amb}}$ by definition, (ii) directly follows from (i). Let $(x,t_0)$ be a point on $M \times \{t_0\}$. By (ii), $D|_{M \times \{t_0\}}$ is a vector bundle on $M \times \{t_0\}$. Let $Z_1$ and $Z_2$ be two local sections of $D|_{M \times \{t_0\}}$ defined near $(x,t_0)$. For every $f$ in $C^\infty_b(M \times U, F_{\text{amb}})$, we have $[Z_1,Z_2]f = \cdots$
\[ Z_1Z_2f - Z_2Z_1f = 0. \] Then \[ Z_1, Z_2 \] is a section of \( \mathcal{D}_{|M \times \{t\}}. \) Hence \( \mathcal{D}_{|M \times \{t\}} \) is integrable, which proves (iii). Let \( L \) be a leaf of the foliation defined by \( \mathcal{D}_{|M \times \{t_0\}}. \) Let \( x \) be a point in \( L. \) Let \( k(t_0) = \dim M - \dim D^0. \) By definition of \( D, \) there exists basic functions \( f_1, f_2, \cdots, f_k(t_0) \) on \( (M \times U, \mathcal{F}^\text{amb}) \) such that \( df_1 \wedge df_2 \wedge \cdots \wedge df_k(t_0) \) is nonzero at \( x. \) Since each \( f_i \) is basic, \( df_1 \wedge df_2 \wedge \cdots \wedge df_k(t_0) \) is nowhere vanishing on an open saturated neighborhood \( U' \) of \( L \) in \( (M \times U, \mathcal{F}^\text{amb}). \) Then the map \( \phi \) defined by

\[
\phi: \quad U' \rightarrow \mathbb{R}^{k(t_0)}
\]

is a submersion such that one of the fibers of \( \phi \) is equal to \( L. \) Shrinking \( U', \) we can assume that the fibers of \( \phi \) are connected. Since each fiber of \( \phi \) is saturated by \( D', \) each leaf of \( D' \) near \( L \) coincides with a fiber of \( \phi. \) Then \( \phi \) gives a local trivialization of a fiber bundle. Hence (iv) is proved.

Since \( D \) is a closed subset of \( T(M \times U) \) by definition of \( D, \) the dimension of \( D_{(x,t)} \) is upper semicontinuous with respect to \( t. \) If the dimension of \( D_{(x,t)} \) is constant with respect to \( t, \) then the leaves of \( D \) are fibers of a smooth submersion whose restriction to \( M \times \{t\} \) is equal to the canonical map \( M \times \{t\} \rightarrow (M \times \{t\})/D^t \) for each \( t. \) In this case, the continuity of the Álvarez class follows without Proposition 21 (see Example 7.1). When the dimension of \( D \) jumps, we have only a family of smooth proper submersions defined by \( D \) which changes discontinuously with respect to \( t. \)

6.2. Verification of the conditions of Proposition 21. Let \( U \) be a connected open set in \( \mathbb{R}^t \) which contains 0. Let \( M \) be a closed manifold, and \( \{\mathcal{F}^t\}_{t \in U} \) be a smooth family of orientable transversely parallelizable foliations of \( M \) over \( U \) given by smooth foliation \( \mathcal{F}^\text{amb} \) of \( M \times U. \) We define a distribution \( D \) on \( M \times U \) by (79). By Lemma 28 (iv), \( D_{|M \times \{t\}} \) defines a foliation \( D^t \) of \( M \times \{t\} \) whose leaves are fibers of a submersion. We denote the projection \( M \times \{0\} \rightarrow (M \times \{0\})/D^0 \) by \( \pi^0_{\mathcal{F}}. \)

To apply Proposition 21 to our situation, we prepare two lemmas.

Lemma 29. There exist an open neighborhood \( U' \) of 0 in \( U \) and a smooth proper submersion \( \pi^\text{amb}_{\mathcal{F}}: M \times U' \rightarrow (M \times \{0\})/D^0 \) such that

(i) \( \pi^\text{amb}_{\mathcal{F}}|_{M \times \{0\}} = \pi^0_{\mathcal{F}} \) and

(ii) each fiber of \( \pi^\text{amb}_{\mathcal{F}}|_{M \times \{t\}} \) is saturated by the leaves of \( \mathcal{F}^t \) for each \( t \) in \( U'. \)

Proof. Let \( k = \dim M - \dim D^0. \) For each point \( (x,0) \) on \( M \times \{0\}, \) there exists a \( k \)-tuple of leafwise constant functions \( f_{x1}, f_{x2}, \cdots, f_{xk} \) globally defined on \( (M \times U, \mathcal{F}^\text{amb}) \) such that \( df_{x1} \wedge df_{x2} \wedge \cdots \wedge df_{xk}(x,0) \) is nonzero by definition of \( D. \) Then \( df_{x1} \wedge df_{x2} \wedge \cdots \wedge df_{xk} \) is nowhere vanishing on an open saturated neighborhood \( V_x \) of \( (x,0) \) in \( (M \times U, \mathcal{F}^\text{amb}) \). We define a map \( \phi_x \) by

\[
\phi_x: \quad V_x \rightarrow \mathbb{R}^k
\]

\[
\phi_x(z) = (f_{x1}(z), f_{x2}(z), \cdots, f_{xk}(z)).
\]

This \( \phi_x \) is a submersion, because \( df_{x1} \wedge df_{x2} \wedge \cdots \wedge df_{xk} \) has no zero on \( V_x. \) We can assume that the fibers of \( \phi_x \) is connected after shrinking \( V_x. \) Let \( V_x' = \phi_x^{-1}((\phi_x(V_x \cap (M \times \{0\}))) \). This \( V_x' \) is also an open neighborhood of \( x \) in \( M \times U. \) Since \( \phi_x(V_x') = \)
φ_x(V_z), for each point z on V'_t, there exists a leaf L_z of \( D^0 \) such that \( \phi_x(z) = \phi_x(L_z) \). Since the fibers of \( \phi_x \) are connected, \( L_z \) is unique. We define a map by

\[
\psi_x : V'_t \rightarrow V'_t/D^0 \quad \text{and} \quad z \mapsto L_z.
\]

\( \psi_x \) is a smooth submersion which maps each leaf of \( \mathcal{F}^t \) to a point. Note that \( \psi_x|_{M \times \{0\}} \) is the restriction of the projection \( \pi^0_{\mathcal{F}} \) to \( M \times \{0\} \) by definition. It follows that \( \psi_x|_{M \times \{1\}} \) is a submersion, because \( \psi_x|_{M \times \{t\}} \) is of the same rank with \( \psi_x|_{M \times \{0\}} \). By the compactness of \( M \), there exists a finite set of points \( \{x_j\}_{j=1}^n \) such that \( \bigcup_{j=1}^n V'_{x_j} \) contains \( M \times \{0\} \). There exists an open neighborhood \( U_1 \) of 0 in \( U \) such that \( M \times U_1 \) is contained in \( \bigcup_{j=1}^n V'_{x_j} \). Let \( \{\rho_j\}_{j=1}^n \) be a partition of unity on \( (M \times \{0\})/D^0 \) with respect to a covering \( \{\pi(V'_t \cap (M \times \{0\}))\}_{j=1}^n \). We fix a smooth embedding \( \iota : M \times \{0\} \rightarrow \mathbb{R}^m \) to the \( m \)-dimensional Euclidean space. We define a map \( \Psi_1 \) by

\[
\Psi_1 : M \times U_1 \rightarrow \mathbb{R}^m, \quad z \mapsto \sum_{j=1}^n \rho_j(\psi_{x_j}(z)) \iota(\psi_{x_j}(z)).
\]

Note that each leaf of \( \mathcal{F}^t \) is mapped to a point by \( \Psi_1 \) by definition. \( \Psi_1|_{M \times \{0\}} \) is equal to \( j \circ \pi^0_{\mathcal{F}} \) by definition. Since \( \psi_x|_{M \times \{1\}} \) is a submersion to \( (M \times \{0\})/\mathcal{F} \) and \( \iota \) is an embedding, there exists an open neighborhood \( U_2 \) of 0 in \( U_1 \) such that \( \Psi_1|_{M \times \{t\}} \) is a map of constant rank for every \( t \) in \( U_2 \). Hence \( \Psi_1(M \times \{t\}) \) is a smooth submanifold of \( \mathbb{R}^m \), and \( \Psi_1|_{M \times \{t\}} \) is a smooth submersion on the image for \( t \) in \( U_2 \). There exists an open neighborhood \( U' \) of 0 in \( U_2 \) such that \( \Psi_1(M \times \{t\}) \) is the image of a section of the normal bundle in a tubular neighborhood \( W \) of \( \iota(M \times \{0\}) \) for every \( t \) in \( U' \). We denote the projection \( \pi^\text{amb} = p_W \circ j \circ \Psi_1|_{M \times \{t\}} \). Then \( \pi^\text{amb} \) is a submersion and an extension of \( \pi^0_{\mathcal{F}} \) which satisfies the given conditions.

\[ \square \]

Let \( \pi^t_{\mathcal{F}} = \pi^\text{amb}|_{M \times \{t\}} \) for \( t \) in \( U' \). We write \( \mathcal{F}^t \) for a foliation of \( M \times \{t\} \) defined by the fibers of \( \pi^t_{\mathcal{F}} \).

**Lemma 30.** There exists a smooth family \( \{g^t\}_{t \in U'} \) of Riemannian metrics on \( M \) such that

(i) \( g^t \) is bundle-like with respect to both of \( (M, \mathcal{F}^t) \) and \( (M, \mathcal{F}^t) \) and

(ii) the leaves of \( \mathcal{F}^t \) are minimal submanifolds of \( (M \times \{t\}, g^t) \) for each \( t \) in \( U' \).

In particular, the conditions (a) and (b) of Proposition 21 are satisfied by \( M \times \{0\}, \mathcal{F}^0, \mathcal{F}^0 \) and \( g^0 \).

**Proof.** It is well known that a Riemannian foliation \( \mathcal{G} \) on a closed manifold \( N \) defined by a proper submersion is minimizable. For example, see Corollary 2 of Haefliger 12. Then there exists a Riemannian metric \( g^\text{amb} \) on \( M \times U' \) which is bundle-like with respect to the foliation defined by the fibers of \( \pi_{\mathcal{F}} \) and each leaf of \( \mathcal{F} \) is a minimal submanifold of \( (M \times U', g^\text{amb}) \). Let \( g^t_1 = g^\text{amb}|_{M \times \{t\}} \). Then the leaves of \( \mathcal{F}^t \) are minimal submanifolds of \( (M \times \{t\}, g^t_1) \). Let \( \lambda^t \) be the characteristic form of \( (M \times \{t\}, \mathcal{F}^t, g^t_1) \). We can take a family of metrics \( \{g^t_2\}_{t \in U} \) on a family of vector bundles \( T(M \times \{t\})/T\mathcal{F}^t \cong (T\mathcal{F}^t)^\perp \) on \( M \) such that \( g^t_2 \) is transverse with respect to both of \( \mathcal{F}^t \) and \( \mathcal{F}^t \). We can extend the family of metrics \( \{g^t_2\}_{t \in U} \) on \( \{T\mathcal{F}^t\}^\perp \) on \( U \).
to a family of Riemannian metrics \( \{g^t\}_{t \in U} \) on \( M \) so that the characteristic form of 
\((M, \overline{F}^t, g^t)\) is equal to \( \overline{\chi}^t \). Then \( g^t \) is bundle-like with respect to both of \( F^t \) and \( \overline{F}^t \). By the Rummler’s formula (see the second formula in the proof of Proposition 1 in Rummel [24] or Lemma 10.5.6 of Candel and Conlon [4]), the mean curvature form
\nBy the Rummler’s formula (see the second formula in the proof of Proposition 1 in
\n\[ \sum_{1 \leq j < k \leq q} c^j_k \omega_j \wedge \omega_k \] for some functions \( c^j_k \) on \( M \times U \). We have
\n\[ d \omega_i (X^j_{amb}, X^k_{amb}) = c^j_k. \]

Since \( d \omega_i \) and each \( \omega_j \) are basic forms and \( X^j_{amb} \) is a transverse field on \( (M \times U, F^{amb}) \), \( c^j_k \) is a basic function on \( (M \times U, F^{amb}) \). Hence the restriction of \( c^j_k \) to each fiber of \( \overline{F}^0 \) is a constant by definition of \( D \). This proves that the condition (c) is satisfied.

Let \( \beta \) be a 1-form on \( (M \times \{0\})/\overline{F}^0 \). Then \( \pi_\overline{F}^0 \beta \) is a basic 1-forms on \( (M \times U, F^{amb}) \). It follows that \( \pi_\overline{F}^0 \beta (X^i_{amb}) \) is a global basic function on \( (M \times U, F^{amb}) \). Hence the restriction of \( \pi_\overline{F}^0 \beta (X^i_{amb}) \) to each fiber of \( \overline{F}^0 \) is a constant by definition of \( D \). Hence the image of \( X^i_{amb} |_{M \times \{0\}} \) by the canonical projection \( C^\infty(T(M \times \{0\})/T\overline{F}^0) \rightarrow C^\infty(T(M \times \{0\})/T\overline{F}^0) \) is a transverse field on \( (M \times \{0\}, \overline{F}^0) \). This proves that the condition (d) is satisfied.

6.3. Proof of the continuity Theorem 1

Let \( M \) be a closed manifold and \( \{F^t\}_{t \in U} \) be a smooth family of transversely parallelizable foliations of \( M \) over \( U \).

We consider the distribution \( D \) defined by the equation (79). By Lemma 28, a proper submersion \( \pi_0^F : M \times \{0\} \rightarrow (M \times \{0\})/D^0 \) is defined by the restriction of \( D \) to \( M \times \{0\} \). By Lemma 29, we can take an open neighborhood \( U' \) of 0 in \( U \) and a proper submersion \( \pi^F_{amb} : M \times U' \rightarrow (M \times \{0\})/D^0 \) such that \( \pi^F_{amb} |_{M \times \{t\}} = \pi_0^F \) and each fiber of \( \pi^F_{amb} |_{M \times \{t\}} \) are saturated by the leaves of \( F^t \) for each \( t \) in \( U' \). We denote the foliation of \( M \times \{t\} \) defined by the fibers of \( \pi^F_{amb} |_{M \times \{t\}} \) by \( \overline{F}^t \). By Lemma 30, we take a smooth family of metrics \( \{g^t\}_{t \in U'} \) on \( M \) such that the fibers of \( \pi^F_{amb} \) are minimal submanifolds of \( (M \times \{t\}, g^t) \) and \( g^t \) is bundle-like with respect to both of \( (M, F^t) \) and \( (M, \overline{F}^t) \) for each \( t \) in \( U' \). We denote the mean curvature form and the Álvarez form of \( (M, F^t, g^t) \) by \( \kappa^t \) and \( \kappa^t_{amb} \), respectively. We define \( \kappa^t_{amb} = \rho^F \kappa^t \).

Let us show Theorem 1 by using Proposition 21 and Corollary 4.23 of Domínguez in [5].
Proof of Theorem 7. By Lemma 18, it suffices to show the case where $M, \tilde{F}^0$ and the basic fibration of $(M, \mathcal{F}^0)$ are orientable. By Lemmas 30 and 31, the conditions (a), (b), (c) and (d) of Proposition 21 are satisfied. Hence, by Proposition 21, $\tilde{\kappa}_b^0$ is closed and $[\tilde{\kappa}_b^0] = [\kappa_b^0]$. By Corollary 4.23 of Domínguez [5], we can modify the component $g^t|_{T\mathcal{F}^0 \otimes T\mathcal{F}^t}$ along the leaves of $\{g^t\}_{t \in T'}$ so that $\kappa_b^0 = \tilde{\kappa}_b^0$. Note that $\tilde{\kappa}_b^t$ may not be closed for nonzero parameter $t$ in $T'$.

For a smooth loop $\gamma$ in $M$, we have the following evaluation:

$$\left| \int_{\gamma} (\tilde{\kappa}_b^0 - \kappa_b^t) \right| \leq \left| \int_{\gamma} (\tilde{\kappa}_b^0 - \tilde{\kappa}_b^t) \right| + \left| \int_{\gamma} (\tilde{\kappa}_b^t - \kappa_b^t) \right| = \left| \int_{\gamma} (\tilde{\kappa}_b^0 - \tilde{\kappa}_b^t) \right| + \left| \int_{\gamma} \rho_F (\tilde{\kappa}_b^t - \kappa_b^t) \right| \leq \left| \int_{\gamma} (\tilde{\kappa}_b^0 - \tilde{\kappa}_b^t) \right| + \left( \sup_{s \in \mathbb{S}^1} \left| \frac{d\gamma}{ds} (s) \right| \right) \left( \sup_{x \in M \times \{t\}} \left| \tilde{\kappa}_b^t (x) - \kappa_b^t (x) \right| \right),$$

where $\| \cdot \|$ is a norm induced by $g^t$. Since $\tilde{\kappa}_b^t$ converges to $\tilde{\kappa}_b^0 = \kappa_b^0$, the first and the second term converges to 0 as $t$ tends to 0. Then we have $\lim_{t \to 0} \int_{\gamma} \kappa_b^t = \int_{\gamma} \tilde{\kappa}_b^0$ and the proof is completed.

By Proposition 5.3 of Álvarez López [1], every closed 1-form cohomologous to the Álvarez class of $(M, \mathcal{F}^0)$ is realized as the Álvarez form of $(M, \mathcal{F}^t, g)$ for some bundle-like metric $g$. Proposition 5.3 of Álvarez López is simpler to prove than the Corollary 4.23 of Domínguez [5], which is used in the proof of Theorem 1 above. But we do not know if we can replace Corollary 4.23 of [5] by Proposition 5.3 of [1] in the proof of Theorem 1.

In fact, by Proposition 5.3 of [1], we can modify the component $g^t|_{T\mathcal{F}^0 \otimes T\mathcal{F}^t}$ along the leaves of $\{g^t\}_{t \in T'}$ so that $\kappa_b^0 = \tilde{\kappa}_b^0$. But we do not know if $\left| \int_{\gamma} (\tilde{\kappa}_b^t - \kappa_b^t) \right|$ converges to 0 as $t$ goes to 0 here. Note that $\left| \int_{\gamma} (\tilde{\kappa}_b^t - \kappa_b^t) \right|$ may not converge to 0 as $t$ goes to 0 in this situation. This is because $\kappa_b^t$ is defined by integrating the mean curvature form on each leaf closure of $\mathcal{F}^t$ and the dimension of the closures of leaves of $\mathcal{F}^t$ can change on any small open neighborhood of 0.

7. Examples of Riemannian foliations

7.1. A special case where the families of Molino’s commuting sheaves are smooth. Let $\{\mathcal{F}^t\}_{t \in T}$ be a family of Riemannian foliations on a closed manifold $M$.

If the dimension of the closures of generic leaves of $\mathcal{F}^t$ is constant with respect to $t$, then the family of Molino’s commuting sheaves of $\{\mathcal{F}^t\}$ is smooth (see pages 125–130 and Section 5.3 of Molino [19] for the definition of the Molino’s commuting sheaf of a Riemannian foliation). Since the Álvarez class of $(M, \mathcal{F}^t)$ is computed from the holonomy homomorphism of the Molino’s commuting sheaf of $(M, \mathcal{F}^t)$ by Theorem 1.1 of Álvarez López [2], the Álvarez classes of this family are continuous with respect to $t$. Our main continuity Theorem 1 is essential in the case where the dimension of the closures of leaves changes. If the dimension of the closures of leaves changes, we cannot prove the continuity of the Álvarez class as above or directly by an application of deformation theory to Molino’s commuting sheaves.
In fact, the family of the Molino’s commuting sheaves must be discontinuous in this case, because the rank of the Molino’s commuting sheaf is equal to the dimension of the closures of generic leaves of $\mathcal{F}^t$.

7.2. Families of homogeneous Lie foliations. Let $p: L \longrightarrow G$ be a surjective homomorphism between Lie groups. Let $\Gamma$ be a uniform lattice of $L$. A foliation $\mathcal{F}$ on a homogeneous space $\Gamma \backslash L$ is induced by the fibers of $p$. This $\mathcal{F}$ has a structure of a $G$-Lie foliation. Such $\mathcal{F}$ is called a homogeneous $G$-Lie foliation. By deforming $L$, $G$, $p$, and $\Gamma$, we may produce families of homogeneous Lie foliations. The Álvarez class is computed in terms of Lie theory by the interpretation of the Álvarez class as a first secondary characteristic class of Molino’s commuting sheaf by Álvarez López (Theorem 1.1 of [2]). But the author does not know an example of a family of Riemannian foliations whose Álvarez classes change nontrivially obtained in this way. In many cases, the Álvarez class does not change as we will see in the following.

If $G$ is nilpotent, then $\mathcal{F}$ is of polynomial growth. Then the Álvarez class does not change under deformations of $\mathcal{F}$ by Corollary 3. If $L$ is solvable, then $\Gamma$ is polycyclic (see Proposition 3.7 of Raghunathan [22]). Then the Álvarez class does not change under deformations of $\mathcal{F}$ by Corollary 3. If $G$ is semisimple, the structural Lie algebra of the Lie foliation defined on the closure of leaves of $\mathcal{F}$ is semisimple. Then $\mathcal{F}$ is minimizable by Theorem 2 of Nozawa [20].

7.3. Meigniez’s examples: Families of solvable Lie foliations. Meigniez constructed plenty of families of solvable Lie foliations which are not homogeneous by a surgery construction on homogeneous Lie foliations in [16] (see also [17], in particular, pages 119–122 for an explicit example). These families contain many examples of families of Lie foliations whose Álvarez classes change nontrivially.

7.4. Basic cohomology of Riemannian foliations is not invariant under deformations. We present an example of a family of Riemannian foliations whose basic cohomology changes. Let $M = S^1 \times S^3$. Let $\sigma$ be the free $S^1$-action on $S^3$ whose orbits are fibers of the Hopf fibration. Let $\rho$ be the $T^2$-action on $M$ which is the product of the principal $S^1$-action on the first $S^1$-component and $\sigma$. For each element $v$ of Lie$(T^2) \setminus \{0\}$, let $\mathcal{F}_v$ be the Riemannian flow on $M$ whose leaves are the orbits of an $\mathbb{R}$-subaction of $\rho$ whose infinitesimal action is given by $v$. Then we have a smooth family $\{\mathcal{F}_v\}_{v \in \text{Lie}(T^2) \setminus \{0\}}$ of Riemannian flows on $M$. Let $v_1$ and $v_2$ be the infinitesimal generators of the principal $S^1$-action on the first $S^1$-component and $\sigma$, respectively. Since $M/\mathcal{F}_{v_1} = S^3$ and $M/\mathcal{F}_{v_2} = M/\sigma = S^1 \times S^2$, clearly the dimension of $H^1_b(M/\mathcal{F}_{v_1})$ and $H^1_b(M/\mathcal{F}_{v_2})$ are different.

8. Examples of non-Riemannian foliations

8.1. Turbulization. Let $\mathcal{F}^1$ be a product foliation $T^2 = \bigcup_{\theta_1 \in S^1} \{\theta_1\} \times S^1$ on $T^2$. Let $\mathcal{F}^0$ be a turbulization of $\mathcal{F}^1$ along a closed curve $\{\frac{1}{2}\} \times S^1$. This $\mathcal{F}^0$ is not minimizable by a theorem of Sullivan (see [26]), because $\mathcal{F}^0$ has a tangent homology defined by the Reeb component. Note that $\mathcal{F}^0$ is a limit of 1-dimensional foliations on $T^2$ which are diffeomorphic to $\mathcal{F}^1$. Thus we have a family of 1-dimensional foliations on $T^2$ parametrized by $[0, 1]$ such that only $\mathcal{F}^0$ is not minimizable.
8.2. **Deformation of an example of Candel and Conlon.** We present an example of a family \( \{ F_t \}_{t \in [0,1]} \) of 1-dimensional foliations on \( S^3 \) such that \( F^0 \) is not minimizable and \( F^1 \) is minimizable if \( t \) is nonzero. In a similar way, we will construct a family \( \{ H_t \}_{t \in [0,1]} \) of 1-dimensional foliations on \( S^3 \) such that \( H^1 \) is minimizable and \( H^t \) is minimizable if \( t \) is not equal to 1. Here \( F^0 \) and \( H^0 \) are the example constructed by Candel and Conlon in Example 10.5.19 of [4]. These examples show that the minimizability is neither open nor closed in families of foliations in general.

We restate the construction of the example \( F^0 \) of Candel and Conlon here. We consider the 2-dimensional product foliation \( S^1 \times D^2 = \coprod_{t \in S^1} \{ t \} \times D^2 \) on the solid torus. Turbulizing this product foliation around the axis \( S^1 \times \{0\} \), we obtain a singular foliation \( S \) on \( S^1 \times D^2 \) whose leaves are trumpet-like surfaces and the axis \( S^1 \times \{0\} \). We foliate \( S^1 \times D^2 \) by a 1-dimensional foliation \( G^0 \) so that each leaf of \( S \) is saturated by leaves of \( G^0 \) and the leaves of \( G^0 \) are transverse to the boundary of the solid torus. We obtain a foliation \( F^0 \) on \( S^3 \) by pasting two copies of \( (S^1 \times D^2, G^0) \). This \( (S^3, F^0) \) is non-minimizable as Candel and Conlon showed by a theorem of Sullivan in Example 10.5.19 of [4].

We construct \( F^t \) for nonzero \( t \) in \([0,1]\). Let \( L_1 \) and \( L_2 \) be two closed leaves of \( F^0 \) which are axes of solid tori. For \( t \) in \([0,1]\), let \( F^t \) be the smooth foliation obtained from \( F^0 \) by replacing both of \( L_1 \) and \( L_2 \) to solid tori \( K^t_1 \) and \( K^t_2 \) of radius \( t \) with the product foliation \( K^t_i = S^1 \times D^2 = \coprod_{x \in D^2} S^1 \times \{x\} \) for \( i = 1 \) and 2. Thus we have a smooth family \( \{ F^t \}_{t \in [0,1]} \) of 1-dimensional foliations on \( S^3 \).

We can decompose \( S^3 \) into \( F^t \)-saturated subsets \( K^t_1, K^t_2 \) and \( T^2 \times [0,1] \). Let \((\theta_1, \theta_2, s)\) be the coordinates on \( T^2 \times [0,1] \) such that
• $\theta_1$ parametrizes a meridian of $K^t_1$ and a longitude of $K^t_2$, and
• $\theta_2$ parametrizes a meridian of $K^t_2$ and a longitude of $K^t_1$.

By the construction, we can construct $\mathcal{F}^t$ so that the leaves of $\mathcal{F}^t$ are transverse to a 1-form $d\theta_1 + d\theta_2$ on $T^2 \times [0, 1]$.

By the Rummler-Sullivan criterion, let us show

**Proposition 32.** $\mathcal{F}^t$ is minimizable for nonzero $t$ in $[0, 1]$.

**Proof.** By the Rummler-Sullivan criterion (see Sullivan [25]), $\mathcal{F}^t$ is minimizable if and only if there exist a 1-form $\chi$ on $S^3$ such that $\chi|_{\mathcal{F}^t}$ has no zero and $d\chi|_{\mathcal{T}^{\mathcal{F}^t}} = 0$.

We take the decomposition of $S^3$ into $\mathcal{F}^t$-saturated subsets

\[ S^3 = K^t_1 \cup K^t_2 \cup (T^2 \times [0, 1]) \tag{86} \]

as above. We take a coordinate $(\theta_1, \theta_2, s)$ on $T^2 \times [0, 1]$ as noted in the paragraph previous to Proposition 32. We assume that $\mathcal{F}^t$ is transverse to $d\theta_1 + d\theta_2$ on $T^2 \times [0, 1]$, while $\mathcal{F}^t|_{K^t_1}$ is the product foliation on a solid torus for $i = 1$ and 2. Let $A_i$ be the axis of $K^t_i$. We can extend $\theta_i$ from $T^2 \times [0, 1]$ to $S^3 - A_1$ so that

• $\theta_1$ is the composite of a diffeomorphism $S^3 - A_1 \cong S^1 \times D^2$ and the first projection $S^1 \times D^2 \to S^1$ and
• $d\theta_1$ is transverse to $\mathcal{F}^t$ on $S^3 - K^t_2$.

We extend $\theta_2$ to $S^3 - A_2$ in a similar way.

Let $r_i$ be the radius coordinate on the $D^2$-component of $K^t_i$. Let $\phi_i$ be a non-negative smooth function on $S^3$ such that

• $\phi_i = 0$ on $S^3 - K^t_i$,
• $\phi_i$ is a function of $r_i$ on $K^t_i$ and
• $\phi_i$ is 1 on an open neighborhood of $A_i$.

We define a 1-form $\chi$ on $S^3$ by

\[ \chi = (1 - \phi_1) d\theta_1 + (1 - \phi_2) d\theta_2. \tag{87} \]

Note that $(1 - \phi_i) d\theta_i$ is well-defined on $S^3$, though $d\theta_i$ is not defined on the axis $A_i$ of $K^t_i$.

We will confirm that $\chi$ satisfies the conditions in the Rummler-Sullivan’s criterion for $\mathcal{F}^t$ on the components of the decomposition (86). Since the restriction of $\chi$ to $T^2 \times [0, 1]$ is equal to $d\theta_1 + d\theta_2$, $\chi|_{T^2 \times [0, 1]}$ is transverse to $\mathcal{F}^t|_{T^2 \times [0, 1]}$ and $d\chi = 0$. On $K^t_1$, we have

\[ \chi|_{K^t_1} = (1 - \phi_1) d\theta_1 + d\theta_2 \tag{88} \]

Since $d\theta_2$ is transverse to $\mathcal{F}^t|_{K^t_1}$ and $d\theta_1|_{\mathcal{T}^{\mathcal{F}^t}}$ is zero, $\chi|_{K^t_1}$ is transverse to $\mathcal{F}^t|_{K^t_1}$. We have $d\chi|_{K^t_1} = d\phi_1 \wedge d\theta_1$, and hence $(d\chi|_{K^t_1})|_{\mathcal{T}^{\mathcal{F}^t}} = 0$. We can prove that $\chi|_{K^t_2}$ also satisfies the two conditions in the Rummler-Sullivan’s characterization in the same way. Hence $\mathcal{F}^t$ is minimizable.

Let $X^s$ be a nowhere vanishing vector field tangent to $\mathcal{F}^s$ for $s = 0$ and 1. Let $X^t = tX^1 + (1 - t)X^0$ for $0 < t < 1$. Then $X^t$ is nowhere vanishing and defines a foliation $\mathcal{H}^t$. In this family $\{\mathcal{H}^t\}_{t \in [0, 1]}$ of foliations, $\mathcal{H}^t$ is non-minimizable for $0 \leq t < 1$ and $\mathcal{H}^1$ is minimizable. In fact, $\mathcal{H}^t$ is shown to be non-minimizable for $0 \leq t < 1$ by an argument similar to the proof of non-minimizability of $\mathcal{F}^0$ by Candel and Conlon in Example 10.5.19 of [4]. The proof of the minimizability of $\mathcal{H}^1$ is similar to the proof of Proposition 32.
