In ureteric microvessels the antagonistic relationship between Ca²⁺ signalling in endothelium and Ca²⁺ oscillations in myocytes and pericytes of arterioles and venules involves nitric oxide (NO), but the underlying mechanisms are not well understood. In the present study we investigated the effects of carbachol and NO donor SNAP on Ca²⁺ signalling and vasomotor responses of arterioles and venules in intact ureteric microvascular network in situ using confocal microscopy. Vasomotor responses of arterioles and venules induced by AVP correlated with the occurrence of Ca²⁺ oscillations in the myocytes and pericytes and were not abolished by the removal of Ca²⁺ from extracellular fluid. Carbachol-induced rise of intracellular Ca²⁺ in endothelium was accompanied by the termination of the Ca²⁺ oscillations in myocytes and pericytes. This carbachol-induced inhibitory effect on Ca²⁺ oscillations in myocytes and pericytes was reversed by ODQ, an inhibitor of soluble guanylyl cyclase (sGC) and by Rp-8-pCPT-cGMPs, an inhibitor of protein kinase G (PKG). Ca²⁺ oscillations in myocytes and pericytes were also effectively blocked by NO donor SNAP. An inhibitory effect of SNAP was markedly enhanced by zaprinast, a selective inhibitor of cGMP-specific phosphodiesterase-5, and reversed by sGC inhibitor, ODQ and PKG inhibitor, Rp-8-pCPT-cGMPs. The cGMP analogue and selective PKG activator 8pCPT-cGMP also induced inhibition of the AVP-induced Ca²⁺ oscillations in myocytes and pericytes. SNAP had no effects on Ca²⁺ oscillations induced by caffeine in distributing arcade arterioles. Consequently, we conclude that NO-mediated inhibition of Ca²⁺ oscillations in myocytes and pericytes predominantly recruits the cGMP/PKG dependent pathway. The inhibitory effect of NO/cGMP/PKG cascade is associated with suppressed Ca²⁺ release from the SR of myocytes and pericytes selectively via the inositol triphosphate receptor (IP₃R) channels.

1. Introduction

An endothelial cell (EC) Ca²⁺ signalling is implicated in regulation of the arteriolar and venular microvascular tone and involves antagonistic relationship between Ca²⁺ signals in endothelial and media cells (myocytes and pericytes) [1–6]. For example, dilation of ureteric arterioles and venules [6] or hamster cheek pouch arterioles [7] in response to the endothelium-dependent vasodilator carbachol (CCh) or acetylcholine (ACh) is associated with an increase in ECs Ca²⁺ signalling which terminates agonist induced Ca²⁺ signals in smooth muscle cells and pericytes. In myocytes and pericytes of ureteric microvessels the antagonistic relationship between Ca²⁺ signalling in endothelium and media cells is NO-mediated [6]. An increase in the intracellular concentration of free Ca²⁺ ([Ca²⁺]i) in ECs activates Ca²⁺/calmodulin-dependent constitutive endothelial NO synthase (eNOS) to generate NO, which diffuses to the adjacent myocytes or pericytes and binds to a prosthetic group on soluble guanylyl cyclase (sGC). Stimulated sGC catalyses synthesis of the second messenger cGMP, which in turn activates cGMP-dependentPKG and/or other effector proteins, including ion channels, pumps, and phosphodiesterases (PDEs) [8]. Impaired NO and cGMP signalling have been implicated in the pathogenesis of cardiovascular disease and atherosclerosis [9–11]. In large blood vessels ACh-induced dilations are mainly mediated by NO/cGMP/cGKI pathway [12,13]. The importance of NO and cGMP for the regulation of vascular tone and blood pressure has been recently strengthened by the observation that cGMP, eNOS, or cGKI deficiency in mice lead to pathological changes in vascular wall and hypertension development [12,14,15]. Although, the involvement of the sGC/cGMP pathway in the pharmacological actions of NO...
is widely accepted, there are data suggesting that alternative NO-mediated cGMP-independent pathways also exist. It is accepted that NO-induced vasodilation can be classified as cGMP-dependent as long as it is completely inhibited by the selective blocker of soluble guanylate cyclase, ODQ (1H-[1,2,4]oxadiazole[4,3-a]quinoxalin-1-one) [16–18]. However, in some blood vessels a lack of ODQ effect on NO-induced inhibition of Ca\(^{2+}\) signalling and tone was reported and contribution of cGMP-independent mechanisms was suggested [18–24]. We hypothesized that in myocytes and pericytes of ureteric microvessels, NO activates a cGMP/PKG-dependent pathway. To test this hypothesis we examined the effects of putative pharmacological modulators of NO/cGMP/PKG pathway on the endothelium-mediated inhibition of AVP-induced Ca\(^{2+}\) oscillations in myocytes and pericytes of ureteric microvascular networks in situ in the absence and presence of external Ca\(^{2+}\). To achieve this goal we used our unique methodology developed back in 2003 [25] of real time confocal imaging of intact microvascular networks \textit{in situ}, which allows to monitor simultaneously an intracellular [Ca\(^{2+}\)] in myocytes, pericytes and endothelial cells and correlate it with vasmotor activity [6,26].

2. Methods

2.1. Animals and ureteric tissue samples

The experiments were performed on Wistar rats of both sexes (3–4 months old). Rats were humanely killed using CO\(_2\) anaesthesia followed by cervical dislocation, in accordance with UK legislation. Whole ureters were dissected, carefully cleaned of connective and paraureteric adipose tissue using fine curved scissors and keeping the sharp edges away from the tissue to avoid physical damage of the ureteric bundles.

2.2. Calcium and diameter measurements

For Ca\(^{2+}\) measurements ureters were cut into small segments (4–5 mm long) and loaded with Fluo-4. Strips of ureter were placed in a plastic cuvette containing 1 ml of HEPES-buffered Krebs solution including 15 μM-fluo 4-AM dissolved in dimethyl sulphoxide premixed with Pluronic F127 (final concentration of 0.01%). Loading was performed at 23 °C for 3 h with the cuvettes wrapped in black tape and rotated at 30 rpm. Tissue samples were then removed from the loading medium and placed in normal Krebs solution for at least 30 min to allow cleavage of fluo 4-AM to fluo 4 by intracellular esterases. Fluo-4 loaded segments of ureter were transferred to a custom-made perfusion chamber mounted on the stage of inverted Olympus microscope. Superfusion of the ureteric segments in the chamber was performed by applying a positive pressure valve controlled flow of solution \textit{via} a 1 mm diameter tip attached to a 3-d mechanical manipulator (Narishige, Japan) which allowed positioning the superfusion tip in a desired region of the chamber. Solution was removed by suction at the other end of the chamber. All experiments were performed at 30 °C. We used a Nikon epifluorescence microscope [6,25,26] (Ultraview, PerkinElmer), connected to an iXon cooled charge-coupled device camera (Andor Technology, UK). Andor Technology iQ or iQ2 data acquisition software was used for 2- and 3-dimensional confocal imaging of ureteric microvascular networks \textit{in situ}. Images were collected at 33-66 frames per second using a \( \times 60 \) water objective (NA 1.20) for spatial resolution or dry (\( \times 10 \), NA 0.42; \( \times 20 \), 0.70 NA) for a larger field of viewing.
view. To measure elemental events and Ca\textsuperscript{2+} waves in myocytes and pericytes, tangential sections were used, whereas radial sections through the centre of the microvessel were used to measure Ca\textsuperscript{2+} events in myocytes, pericytes, endothelial cells and changes in vessel diameter. Mechanical activity of individual smooth muscle cells was tracked by putting the region of interest close to the edge of the contracting cell. It was possible to correlate Ca\textsuperscript{2+} signalling with contraction of individual myocytes and pericytes in both radial and tangential sections.

2.3. Solutions

Physiological saline of the following composition was used (mM): NaCl 120.4, KCl 5.9, MgSO\textsubscript{4} 1.2, CaCl\textsubscript{2} 2, glucose 11.5, and HEPES 11. The Ca\textsuperscript{2+}-free solutions contained 2 mM EGTA. [Arg\textsuperscript{8}]-Vasopressin acetate salt (AVP), Carbachol (CCh), Caffeine, Zaprinast (ZAP), 1H-[1,2,4]Oxadiazolo[4,3-a]quinoxalin-1-one (ODQ), S-nitroso-N-acetyl-DL-penicillamine (SNAP), DL-penicillamine (SNAP), Fluo-4 acetoxymethyl (AM) ester was from Molecular Probes, Life Technologies, UK.

2.4. Statistics

A paired Student’s t test was used to test for significant differences between means. All statistical values are expressed as mean ± SEM.

3. Results

3.1. Effect of sGC inhibition

To evaluate whether inhibition of AVP (5 nM)-induced Ca\textsuperscript{2+} oscillations in myocytes and pericytes of arteriolar and venular
microvessels by CCh or SNAP is cGMP-dependent, we examined the effect of ODQ (25 μM), a selective inhibitor of NO-binding site on sGC, in the presence and absence of external Ca²⁺. Both myocytes and pericytes retain their ability to generate Ca²⁺ signalling and tone in the absence of an external Ca²⁺ [6, 26]. In these experiments we found that termination of sustained AVP-induced Ca²⁺ oscillations and vasomotor activity in myocytes and pericytes was associated with CCh (2 μM)-induced Ca²⁺ transient in endothelium and was reversed by ODQ which had no effect on Ca²⁺ signalling in endothelium or myocytes on its own (n = 7, Fig. 1A and B, Supplementary Videos 1 and 2). Furthermore, ODQ reversed an inhibitory action of SNAP (10 μM) on AVP-induced Ca²⁺ oscillations in myocytes and pericytes of arterioles and venules, suggesting an involvement of cGMP/PKG-dependent pathway (n = 7, Fig. 2). Similar results have been obtained in the absence of an external Ca²⁺.

3.2. Effects of PKG inhibition

Since the above results suggest that endothelial cell Ca²⁺ signalling and NO donor SNAP inhibit Ca²⁺ oscillations in myocytes and pericytes, acting through NO/cGMP-dependent mechanism, we further investigated whether PKG mediates CCh- and NO-induced inhibitory effect on Ca²⁺ oscillations and tone in myocytes and pericytes. We found that a selective PKG inhibitor Rp-8-pCPT-cGMPS (20 μM) reversed the inhibitory effects of both CCh and SNAP on AVP-induced Ca²⁺ oscillations and tone in myocytes and pericytes of all sections of arterioles and venules in the presence or absence of an external Ca²⁺ (n = 7, Fig. 3 and Supplementary Video 3). These results suggest that PKG is required for NO-induced inhibition of Ca²⁺ oscillations mediated by IP₃R channels in ureteric arteriolar myocytes and venular pericytes (data not shown).

3.3. Effect of PKG activation

To support the idea that SNAP effects on Ca²⁺ oscillations were mediated by PKG, we studied the effect of the potent PKG activator cGMP analogue 8pCPT-cGMP on the AVP induced Ca²⁺ oscillations in myocytes and pericytes of ureteric microvessels. This cGMP analogue is permeable to cell membranes, resistant to hydrolysis by PDEs, and selective activator of cGMP-dependent PKG. 8pCPT-cGMP (100 μM) caused time-dependent decrease in the amplitude and frequency of Ca²⁺ oscillations from 0.07 ± 0.002 Hz to 0.005 ± 0.001 Hz in 60% and completely ceased within 2–5 min in 40% of myocytes observed (n = 7, Fig. 4). These results suggest that raising cGMP targets PKG and induce inhibition of AVP-induced Ca²⁺ oscillations in myocytes and pericytes, leading to vasodilatation.

3.4. Effect of PDE5 blocker zaprinast

Since NO action is mediated by second messenger cGMP with a short life span, we have examined how cGMP catabolism reduction by PDE-5-selective inhibitor zaprinast (ZAP) affected NO-sensitive Ca²⁺ oscillations in myocytes and pericytes of ureteric microvessels. In these experiments the microvessels were given a subthreshold concentration of SNAP (10–50 nM) in which it had no inhibitory effect on AVP induced Ca²⁺ oscillations (n = 5, Fig. 5B) and tone. Fig. 5A shows that ZAP alone had little or no effect on AVP-induced Ca²⁺ oscillations in myocytes and pericytes. However, combined action of SNAP (10 nM) and ZAP (20 μM) completely terminated AVP-induced Ca²⁺ oscillations in myocytes (n = 5, Fig. 5C) and pericytes of all sections of arteriolar and venular networks (data not shown). These data suggest that ZAP enhanced SNAP-mediated inhibition of AVP-induced Ca²⁺ oscillations of ureteric arterioles by suppressing the cGMP-dependent PDE activity.

4. Discussion

In this study by combining confocal imaging with pharmacological analysis we investigated a possible role of NO/cGMP signalling cascade in endothelium–mediated Ca²⁺ dependent inhibition of agonist-induced Ca²⁺ oscillations and vasomotor responses in myocytes and pericytes of ureteric microvessels in situ. Previously, we have shown that in myocytes and pericytes of ureteric microvascular network agonist induced Ca²⁺ signalling and vasomotor responses are selectively mediated by IP₃R channels dependent mainly on Ca²⁺ release from the SR. Similar data have been obtained on smooth muscle cells of intrapulmonary arterioles [27]. In addition, we have shown that activation of endothelial Ca²⁺ signalling by CCh (or bradykinin) terminated agonist-induced Ca²⁺ oscillations and vasomotor responses in the presence and absence of an external Ca²⁺. Furthermore, we have shown that antagonistic relationship between Ca²⁺ signalling in endothelium and media cells (myocytes and pericytes) was mainly NO-dependent. Here, we present experimental evidence suggesting that the inhibition of AVP-induced Ca²⁺ oscillations and vasomotor responses...
Ca²⁺ traces of SNAP the cells and (29) the cytes NO 8-pCPT-cGMPS, rylated times. icytes decreased NO, 5. IP3 and membrane-permeable donor SNAP, is inhibited by agonists in myocytes and pericytes. Third, in the presence of zaprinast, a selective inhibitor of cGMP-specific PDE-5 [28], the inhibitory effect of SNAP was amplified more than 10 times. Collectively, these data suggest that cGMP-mediated mechanism is playing a key role in endothelium-dependent inhibition of Ca²⁺ oscillations and vasomotor responses in myocytes and pericytes of ureteric microvascular networks in situ. Our data are in a good agreement with the data obtained on vascular (rat tail artery) [29] and non-vascular (smooth muscle of airways) [28,30] tissues.

In addition, our data also indicate that NO had no effects on caffeine-induced Ca²⁺ oscillations in myocytes of distributing arcade arterioles where functional RyRs have been identified [6]. NO did not influence the magnitude of the Ca²⁺ release induced by caffeine. This result indicates that in myocytes of arcade arterioles, the capacity or Ca²⁺ stores content was not altered significantly and that the RyRs remained unaffected by NO, which agrees with the previous data [24,28]. Collectively, these results suggest that NO, and the resulting increase in cGMP and PKG activity, decreased the frequency of agonist-induced Ca²⁺ oscillations by reducing the activity of the IP₃Rs. The molecular mechanism by which NO/cGMP/PKG signalling cascade inhibited the IP₃R was not investigated here, but an IP₃R-associated cGMP kinase substrate protein called IRAG has been identified in some smooth muscle cells [31,32]. This protein is associated with the IP₃R, is phosphorylated by PKG, and upon phosphorylation it blocks IP₃R activation by IP₃ and Ca²⁺; this could be the major mechanism by which the NO/cGMP/PKG cascade reduces [Ca²⁺], and vascular tone [15] (Fig. 6).

**Fig. 5.** The effect of PDE5 inhibitor ZAP on AVP-induced Ca²⁺ oscillations in myocytes of TA in the absence and presence of the subthreshold concentration of SNAP. (A and B) Ca²⁺ traces showing no effect of ZAP (20 μM) and SNAP (10 nM) on the AVP (5 nM)-induced Ca²⁺ oscillations in single myocytes of AA, respectively; (C) Ca²⁺ trace showing that SNAP in subthreshold concentration completely inhibited AVP-induced Ca²⁺ oscillations in myocytes of AA in the presence of ZAP (n = 5). The data indicate that suppression of PDE5 significantly increased an inhibitory potency of SNAP.

Endothelial cell

![Diagram of Endothelial Cell](image)

**Fig. 6.** Schematic diagram showing signalling pathways involved in antagonistic relationship between Ca²⁺ signalling in endothelial and media (myocytes and pericytes) cells in ureteric microvessels. Agonists, such as CCh in endothelial cells (ECs) and AVP in myocytes and pericytes bind to their specific G protein-coupled membrane receptors (GPCR) and activate phospholipase C to synthesize IP₃, IP₃, in turn, activates IP₃R to release Ca²⁺ from the ER/SR, inducing Ca²⁺ oscillations. Ca²⁺ oscillations in ECs activate eNOS to generate NO, and in myocytes and pericytes myosin light chain kinase (MLCK) to trigger vasoconstriction, NO induces inhibition of Ca²⁺ oscillations in myocytes and pericytes by activating sGC to synthesize cGMP from GTP. The elevation of cGMP activates PKG, which inhibits the IP₃R-mediated Ca²⁺ release (possibly via IRAG phosphorylation), resulting in termination of Ca²⁺ oscillations in media cells.
Finally, we conclude that endothelial cell Ca\(^{2+}\) signalling terminates Ca\(^{2+}\) oscillations in myocytes and pericytes of ureteric microvessels by activation of NO/cGMP/PKG signalling cascade, which results in an inhibition of IP\(_3\)-R-mediated Ca\(^{2+}\) mobilization from the SR.

Conflict of interest

The authors confirm that there are no conflicts of interest.
