ON THE BERNSTEIN-GEL’FAND-GEL’FAND
CORRESPONDENCE AND A RESULT OF
EISENBUD, FLØYSTAD, AND SCHREYER

IUSTIN COANDĂ

Abstract. We show that a combination between a remark of I.N. Bernstein, I.M.
Gel’fand, and S.I. Gel’fand [2] and the idea, systematically investigated by D. Eisen-
bud, G. Fløystad, and F.-O. Schreyer [3], of taking Tate resolutions over exterior
algebras leads to quick proofs of the main results of [2] and [3] (theorems 7 and 10
below). This combination is expressed by lemma 6 from the text, a result which we
prove directly using the cohomology of invertible sheaves on a projective space.

Since the above abstract may serve as an introduction as well, we begin by
recalling (in (0)-(4)) some definitions and facts. We use the Chapter I of [5] as our
main reference for homological algebra (except that we denote mapping cones by
“Con”).

0. Definition. Let $k$ be a field, $V$ an $(n+1)$-dimensional $k$-vector space, $e_0,\ldots,e_n$
a $k$-basis of $V$ and $X_0,\ldots,X_n$ the dual basis of $V^*$. Let $\Lambda = \bigwedge(V)$ be the exterior
algebra of $V$. $\Lambda$ is a (positively) graded $k$-algebra: $\Lambda = \Lambda_0 \oplus \ldots \oplus \Lambda_{n+1}$ with
$\Lambda_i = \bigwedge^i(V)$. Let $\Lambda_+ := \Lambda_1 \oplus \ldots \oplus \Lambda_{n+1}$ and $\mathbb{k} := \Lambda/\Lambda_+$. We denote by $\Lambda$-mod the
category of finitely generated, graded, right $\Lambda$-modules (with morphisms of degree
0).

Let $\mathbb{P} = \mathbb{P}(V)$ be the projective space of 1-dimensional $k$-vector subspaces of $V$
such that $H^0\mathcal{O}_\mathbb{P}(1) = V^*$. If $N \in \text{Ob}(\Lambda$-mod) one defines a bounded complex
$L(N)$ of coherent sheaves on $\mathbb{P}(V)$ by $L(N)^p := \mathcal{O}_\mathbb{P}(p) \otimes_k N_p$ and $d_{L(N)} := \sum_{i=0}^n (X_i \cdot
- \cdot e_i)$. In this way one obtains the BGG functor $L : \Lambda$-mod $\to C^b(\text{Coh}\mathbb{P}(V))$.

It can be extended to a functor $L : C(\Lambda$-mod) $\to C(\text{Coh}\mathbb{P}(V))$ as it follows:
if $K^\bullet$ is a complex in $\Lambda$-mod one considers the double complex $X^{\bullet \bullet}$ in $\text{Coh}\mathbb{P}(V)$
with $X^{p,\bullet} := L(K^p)$ and with $d'^p : X^{p,\bullet} \to X^{p+1,\bullet}$ equal to $L(d^p_K)$ and one takes
$L(K^\bullet) := s(X^{\bullet \bullet})$ the simple complex associated to $X^{\bullet \bullet}$.

The (extended) functor $L$ is exact, commutes with the translation functor $T$
and with mapping cones and maps morphisms homotopically equivalent to 0 to
morphisms with the same property (see [3] remark after (2.5) for a nice argu-
ment) hence it induces a functor $L : K(\Lambda$-mod) $\to K(\text{Coh}\mathbb{P}(V))$. $L$ also maps
quasi-isomorphisms in $K^+(\Lambda$-mod) to quasi-isomorphisms in $K(\text{Coh}\mathbb{P}(V))$, hence
it induces a functor $L : \text{D}^+(\Lambda$-mod) $\to \text{D}(\text{Coh}\mathbb{P}(V))$. 

Typeset by Ams-Tex
We shall often use the following shorter notations: \( K(\Lambda) := K(\Lambda\text{-mod}) \), \( D(\Lambda) := D(\Lambda\text{-mod}) \), \( D(\mathbb{P}) := D(\text{Qcoh}\mathbb{P}(V)) \) and \( D^{b}(\mathbb{P}) := D^{b}(\text{Coh}\mathbb{P}(V)) \).

1. **Definition.** (i) If \( N \in \text{Ob}(\Lambda\text{-mod}) \) and \( a \in \mathbb{Z} \) one defines a new object \( N(a) \) of \( \Lambda\text{-mod} \) by: 
\[
N(a)_p := N_{a+p} \text{ and } (y \cdot v)_{N(a)} := (-1)^a(y \cdot v)_{N}, \; \forall y \in N, \; \forall v \in V.
\]
With this convention, if \( \omega \in \Lambda_b \) then \((- \cdot \omega)_N \) defines a morphism in \( \Lambda\text{-mod} : N(a) \rightarrow N(a + b) \). If \( u : N' \rightarrow N \) is a morphism then \( u(a) : N'(a) \rightarrow N(a) \) is just \( u \) if one forgets the gradings.

One has: \( L(N(a)) = T^aL(N)(-a) \). If \( K^\bullet \) is a complex in \( \Lambda\text{-mod} \), let \( K^\bullet((a)) \) be the complex which coincides with \( K^\bullet(a) \) term by term but with \( d_{K^\bullet((a))} := (-1)^a d_{K(a)} \). Then \( L(K^\bullet((a))) = T^aL(K^\bullet)(-a) \) and if one applies \( L \) to the isomorphism \( (\cdot)^{ap} \cdot \text{id}_{K^\bullet(a)} \) one gets a functorial isomorphism \( L(K^\bullet(a)) \cong T^aL(K^\bullet)(-a) \).

(ii) If \( N \in \text{Ob}(\Lambda\text{-mod}) \) let \( N^\vee \) denote the graded \( k\)-vector space \( \text{Hom}_k(N,k) \) endowed with the following right \( \Lambda \)-module structure: for \( v \in V \), the multiplication \((- \cdot v)_{N^\vee} : (N^\vee)_p \rightarrow (N^\vee)_{p+1} \) is, by definition, \((-1)^{p+1}\cdot\text{the dual of the multiplication } (- \cdot v)_N : N_{-p-1} \rightarrow N_{-p}. \) With this definition, \( L(N^\vee) = \text{Hom}^\bullet_{\text{Gr}}(L(N), \mathcal{O}_{\mathbb{P}}) \).

The canonical isomorphism of \( k\)-vector spaces \( \mu : N \rightarrow (N^\vee)^\vee \) is not a morphism in \( \Lambda\text{-mod} : \mu(y \cdot v) = - \mu(y) \cdot v, \; \forall y \in N, \; \forall v \in V. \) However, \( \mu' := (\cdot)^{ap} \mu_{p \in \mathbb{Z}} \) defines an isomorphism in \( \Lambda\text{-mod} : N \cong (N^\vee)^\vee. \)

(iii) Of a particular importance is the object \( \Lambda^\vee = \bigwedge V^*, \; \forall p \in \mathbb{Z} \) and, for \( v \in V \), the multiplication \((- \cdot v)_{\Lambda^\vee} : (\Lambda^\vee)_p \rightarrow (\Lambda^\vee)_{p+1} \) is the contraction by \( v : (f_1 \wedge \ldots \wedge f_p \cdot v)_{\Lambda^\vee} = \sum_{i=1}^{p} (-1)^{i-1} f_i(v) \cdot f_1 \wedge \ldots \wedge \widehat{f_i} \wedge \ldots \wedge f_p \) for \( f_1, \ldots, f_p \in V^*. \) It follows that \( L(\Lambda^\vee) \) is the tautological Koszul complex on \( \mathbb{P}(V) : \)
\[
0 \rightarrow \mathcal{O}_{\mathbb{P}}(-n-1) \otimes_k \wedge^{n+1} V^* \rightarrow \ldots \rightarrow \mathcal{O}_{\mathbb{P}}(-1) \otimes_k V^* \rightarrow \mathcal{O}_{\mathbb{P}} \rightarrow 0.
\]

(iv) If \( N \in \text{Ob}(\Lambda\text{-mod}) \), \( \text{soc}(N) \) consists of the elements of \( N \) annihilated by \( \Lambda_+ \). In particular, \( \text{soc}(\Lambda) = \Lambda_{n+1} \) and \( \text{soc}(\Lambda^\vee) = (\Lambda^\vee)_0. \)

2. **Remark.** (i) Let \( \mathcal{A} \) be an abelian category. Consider a short exact sequence:
\[
0 \rightarrow X^\bullet \overset{u}{\longrightarrow} Y^\bullet \overset{v}{\longrightarrow} Z^\bullet \rightarrow 0
\]
in the category \( \mathcal{C}(\mathcal{A}) \) of complexes in \( \mathcal{A}. \) Let \( w : Z^\bullet \rightarrow TX^\bullet \) be the morphism in the derived category \( \mathcal{D}(\mathcal{A}) \) defined by the diagram:
\[
\begin{array}{ccc}
Z^\bullet & \overset{(0,v)}{\leftrightarrow} & \text{Con}(u) \overset{(\text{id}_{TX^\bullet},0)}{\rightarrow} TX^\bullet
\end{array}
\]
(recall that \( \text{Con}(u) = TX^\bullet \oplus Y^\bullet \) term by term, not as complexes). Then \((X^\bullet,Y^\bullet,Z^\bullet,u,v,w)\) is a distinguished triangle in \( \mathcal{D}(\mathcal{A}) \) hence \((Y^\bullet,Z^\bullet, TX^\bullet,v,w,-Tu)\) and \((T^{-1}Z^\bullet,X^\bullet,Y^\bullet,-T^{-1}w,u,v)\) are distinguished triangles too. One gets a “long” complex in \( \mathcal{D}(\mathcal{A}) : \)
\[
\ldots \rightarrow T^{-1}Z^\bullet \overset{-T^{-1}w}{\longrightarrow} X^\bullet \overset{u}{\longrightarrow} Y^\bullet \overset{v}{\longrightarrow} Z^\bullet \overset{w}{\longrightarrow} TX^\bullet \overset{-Tu}{\longrightarrow} TY^\bullet \rightarrow \ldots
\]
and for every $W^\bullet \in \text{ObC}(\mathcal{A})$ if one applies $\text{Hom}_{D(\mathcal{A})}(W^\bullet, -)$ or $\text{Hom}_{D(\mathcal{A})}(-, W^\bullet)$ to this long complex one gets long exact sequences in the category $\mathcal{A}b$ of abelian groups.

(ii) Assume that the short exact sequence of complexes from (i) is semi-split, i.e., that
\[
0 \rightarrow X^p \xrightarrow{u^p} Y^p \xrightarrow{v^p} Z^p \rightarrow 0
\]
is split-exact $\forall p \in \mathbb{Z}$, i.e., there exist morphisms $s^p : Z^p \rightarrow Y^p$ and $t^p : Y^p \rightarrow X^p$ such that $t^p \circ u^p = \text{id}_{X^p}$, $v^p \circ s^p = \text{id}_{Z^p}$ and $u^p \circ t^p + s^p \circ v^p = \text{id}_{Y^p}$ (hence $t^p \circ s^p = 0$). Then $\delta := (t^{p+1} \circ d^p_X \circ s^p)_{p \in \mathbb{Z}}$ is a morphism of complexes (i.e., in $\text{C}(\mathcal{A})$) : $Z^\bullet \rightarrow TX^\bullet$ and $w = -\delta$ in $D(\mathcal{A})$ (in fact, $(t^{i}(-\delta, s^p))_{p \in \mathbb{Z}} : Z^\bullet \rightarrow \text{Con}(u)$ is an inverse of $(0, v)$ in $K(\mathcal{A})$).

(iii) Assume that $X^\bullet, Y^\bullet, Z^\bullet \in \text{ObC}^+(\mathcal{A})$ and consider a short exact sequence as in (i). Let $I^\bullet \in \text{ObC}(\mathcal{A})$ be a complex consisting of injective objects of $\mathcal{A}$. Then the functor $\text{Hom}_{K(\mathcal{A})}(\_ , I^\bullet)$ maps quasi-isomorphisms in $K^+(\mathcal{A})$ to isomorphisms in $\mathcal{A}b$, hence it induces a (contravariant) functor : $D^+(\mathcal{A})^\circ \rightarrow \mathcal{A}b$ and if one applies this functor to the “long” complex in $D^+(\mathcal{A})$ defined in (i) one gets a long exact sequence in $\mathcal{A}b$ (because $(X^\bullet, Y^\bullet, \text{Con}(u), u, t(0, \text{id}_Y), (\text{id}_{TX}, 0))$ is a distinguished triangle in $K(\mathcal{A})$).

(iv) We also recall that if $I^\bullet \in \text{ObK}^+(\mathcal{A})$ consists of injective objects of $\mathcal{A}$ then, for every $X^\bullet \in \text{ObK}(\mathcal{A})$, the canonical map $\text{Hom}_{K(\mathcal{A})}(X^\bullet, I^\bullet) \rightarrow \text{Hom}_{D(\mathcal{A})}(X^\bullet, I^\bullet)$ is bijective.

3. Example. (a) Consider (as in [3] par.3) the short exact sequence in $\Lambda$-mod :
\[
0 \rightarrow k \otimes_k V \rightarrow (\Lambda/(\Lambda_+)^2)(1) \rightarrow k(1) \rightarrow 0
\]
let $w : k(1) \rightarrow \text{T}(k \otimes_k V)$ be the morphism in $D^b(\Lambda\text{-mod})$ defined in (2)(i) and let $\nu = \text{T}^{-1}w : \text{T}^{-1}k(1) \rightarrow k \otimes_k V$. If one applies $L$ to the short exact sequence one gets a semi-split short exact sequence in $\text{C}(\text{Coh}\mathbb{P}(V))$. Applying (2)(ii) one derives easily that $L(\nu)$ is the canonical injection : $\mathcal{O}_{\mathbb{P}}(-1) \rightarrow \mathcal{O}_{\mathbb{P}} \otimes_k V$ (recall that the module structure of $(\Lambda/(\Lambda_+)^2)(1)$ differs by sign from the module structure of $\Lambda/(\Lambda_+)^2$).

(b) Dually, consider the short exact sequence in $\Lambda$-mod :
\[
0 \rightarrow k(-1) \rightarrow (\Lambda/(\Lambda_+)^2)^\vee(-1) \rightarrow k \otimes_k V^* \rightarrow 0
\]
and let $\varepsilon : k \otimes_k V^* \rightarrow \text{T}k(-1)$ be the morphism in $D^b(\Lambda\text{-mod})$ defined in (2)(i). Then $L(\varepsilon)$ is the canonical epimorphism : $\mathcal{O}_{\mathbb{P}} \otimes_k V^* \rightarrow \mathcal{O}_{\mathbb{P}}(1)$.

In the next proposition we gather some well-known properties of the category $\Lambda$-mod, stated in [2]. We include a sketch of proof for the reader’s convenience.

4. Proposition. (i) If $N \in \text{Ob}(\Lambda\text{-mod})$ and $a \in \mathbb{Z}$ then the map :
\[
\text{Hom}_{\Lambda\text{-mod}}(N, \Lambda^a(a)) \rightarrow \text{Hom}_k(N_{-a}, \Lambda^a(a)_{-a}) = (N_{-a})^a, \ f \mapsto f_{-a}
\]
is bijective. In particular, \( \Lambda^\vee(a) \) is an injective object of \( \Lambda\text{-mod} \).

(ii) \( \Lambda\text{-mod} \) has enough injective objects.

(iii) In \( \Lambda\text{-mod} : \text{free} \Rightarrow \text{injective} \).

(iv) Every \( N \in \text{Ob}(\Lambda\text{-mod}) \) has a decomposition:

\[
N \cong \Lambda(a_1) \oplus \ldots \oplus \Lambda(a_m) \oplus N^0
\]

with \( m \in \mathbb{N} \), \( a_1 \geq \ldots \geq a_m \) integers and \( N^0 \) annihilated by \( \text{soc}(\Lambda) = \Lambda_{n+1} \). Moreover, \( m, a_1, \ldots, a_m \) and \( N^0 \) (up to isomorphism) are unique.

(v) In \( \Lambda\text{-mod} : \text{projective} \Leftrightarrow \text{free} \Leftrightarrow \text{finite direct sum of } \Lambda\text{-modules of the form } \Lambda^\vee(a) \Leftrightarrow \text{injective} \).

Proof. (i) Let \( f \in \text{Hom}_{\Lambda\text{-mod}}(N, \Lambda^\vee(a)) \). If \( b > a \), \( y \in N_{-b} \) and \( \omega \in \Lambda_{b-a} \) then

\[
f_{-b}(y) \cdot \omega = f_{-a}(y \cdot \omega).
\]

One can use now the fact that the pairing : \( \Lambda^\vee(a)_{-b} \times \Lambda_{b-a} \rightarrow \Lambda^\vee(a)_{-a} = k \) is perfect.

(ii) \( N \) can be embedded into : \( \oplus_a N_{-a} \times_k \Lambda^\vee(a) \).

(iii) One can easily show that : \( \Lambda \cong \Lambda^\vee(-n-1) \).

(iv) For the existence of the decomposition, let \( y \in N \) be a homogeneous element (let’s say, of degree \(-a\)) not annihilated by \( \text{soc}(\Lambda) \). Then \( y\Lambda \cong \Lambda(a) \). By (ii), \( y\Lambda \) is injective in \( \Lambda\text{-mod} \) hence it is a direct summand of \( N \). One concludes by induction on \( \dim_k N \).

For the uniqueness, observe firstly that \( N \cdot \text{soc}(\Lambda) \cong \mathbb{k}(a_1 - n - 1) \oplus \ldots \oplus \mathbb{k}(a_m - n - 1) \). This proves the uniqueness of \( m \) and \( a_1, \ldots, a_m \). Assume, now, that one has an isomorphism:

\[
\varphi : \Lambda(b_1)^{r_1} \oplus \ldots \oplus \Lambda(b_p)^{r_p} \oplus N^0 \cong \Lambda(b_1)^{r_1} \oplus \ldots \oplus \Lambda(b_p)^{r_p} \oplus N^1
\]

with \( b_1 > \ldots > b_p \) and \( N^0, N^1 \) annihilated by \( \text{soc}(\Lambda) \). Applying \(- \cdot \text{soc}(\Lambda)\) one derives that the component of \( \varphi : \Lambda(b_1)^{r_1} \rightarrow \Lambda(b_1)^{r_1} \) is an isomorphism. By a well known trick (about matrices of \( 2 \times 2 = 4 \) blocks with invertible left upper block) it follows that:

\[
\Lambda(b_2)^{r_2} \oplus \ldots \oplus \Lambda(b_p)^{r_p} \oplus N^0 \cong \Lambda(b_2)^{r_2} \oplus \ldots \oplus \Lambda(b_p)^{r_p} \oplus N^1
\]

and one concludes by induction on \( \dim_k N \).

(v) Every projective or injective object of \( \Lambda\text{-mod} \) is a direct summand of a free object (for injective by the proof of (ii)). Now one can apply (iv). \( \square \)

5. **Lemma.** Let \( P^\bullet \in \text{ObC}^-\text{(\Lambda\text{-mod})} \) be a complex bounded to the right of free objects of \( \Lambda\text{-mod} \). Then the complex \( L(P^\bullet) \) is acyclic.

Proof. By definition, \( L(P^\bullet) = s(X^\bullet) \) for a double complex \( X^\bullet \) with \( X^{p,\bullet} = L(P^p) \).

By (1)(iii), the columns of \( X^\bullet \) are acyclic bounded complexes. Now, \( s(X^\bullet) \) is the direct limit of the complexes \( s(\sigma_i^\leq -p X^\bullet) \), \( p \geq 0 \), where \( (\sigma_i^\leq -p X^\bullet)_{ij} = X_{ij} \) for \( i \geq -p \) and \( = 0 \) for \( i < -p \). \( \sigma_i^\leq -p X^\bullet \) is a “first quadrant” type double complex (i.e., \( \exists i_0, j_0 \) such that its \((i, j)\)-component is 0 for \( i < i_0 \) and, also, for \( j < j_0 \)) with acyclic columns, hence \( s(\sigma_i^\leq -p X^\bullet) \) is acyclic. \( \square \)

The next result, which is the key point of this paper, is a generalization of the Remark 3 after theorem 2 in [2]. Its proof can be easily reduced to the particular case \( K^\bullet = k \) of the remark in [2]. In [2], the remark is a consequence of the main result. Here we reverse the order : we prove directly the (general version of the) remark and then we show that it immediately implies the main result of [2].
6. Lemma. Let \( I^\bullet \in \text{ObC}(\Lambda\text{-mod}) \) be an acyclic complex of injective (\( \Leftrightarrow \) free) objects of \( \Lambda\text{-mod} \). For \( p \in \mathbb{Z} \), let \( Z^p := \text{Ker}d^p_i \). Then:

(a) \( \forall p \in \mathbb{Z} \), the canonical morphism \( T^{-p}Z^p \rightarrow I^\bullet \) induces a quasi-isomorphism \( L(T^{-p}Z^p) \rightarrow L(I^\bullet) \).

(b) \( \forall K^\bullet \in \text{ObC}^b(\Lambda\text{-mod}) \), the canonical map:

\[
\text{Hom}_{K(\Lambda)}(K^\bullet, I^\bullet) \rightarrow \text{Hom}_{D(\Lambda)}(L(K^\bullet), L(I^\bullet))
\]

is an isomorphism of \( k \)-vector spaces.

Proof. (a) Let \( \sigma^{\geq p}I^\bullet \) be the “stupid” truncation of \( I^\bullet \) defined by \( (\sigma^{\geq p}I^\bullet)_i = I_i \) for \( i \geq p \) and = 0 for \( i < p \). The morphism \( T^{-p}Z^p \rightarrow I^\bullet \) factorizes as \( T^{-p}Z^p \xrightarrow{\text{qis}} \sigma^{\geq p}I^\bullet \rightarrow I^\bullet \). One has an exact sequence of complexes:

\[
0 \rightarrow \sigma^{\geq p}I^\bullet \rightarrow I^\bullet \rightarrow \sigma^{< p}I^\bullet \rightarrow 0.
\]

By (5), \( L(\sigma^{< p}I^\bullet) \) is acyclic. It follows that \( L(\sigma^{\geq p}I^\bullet) \rightarrow L(I^\bullet) \) is a quasi-isomorphism.

(b) Let \( a := \min\{i \in \mathbb{Z} \mid K^i \neq 0 \} \) and \( b := \min\{j \in \mathbb{Z} \mid K^a_j \neq 0 \} \). Then one has a short exact sequence:

\[
0 \rightarrow K''^\bullet \rightarrow K^\bullet \rightarrow K'''^\bullet \rightarrow 0
\]

with \( K'''^\bullet = T^{-a}(K^a \otimes_k k(-b)) \). Using (2)(iii) and (i) and the Five Lemma one can easily reduce the proof, by induction on \( \sum_i \dim_k K^i \), to the case \( K^\bullet = T^p_k(q) \), \( p, q \in \mathbb{Z} \), and this case reduces immediately to the case \( p = q = 0 \).

In the case \( K^\bullet = k \), using (2)(iv) and the fact that \( TZ^{-1} \rightarrow \sigma^{\geq -1}I^\bullet \) and \( L(TZ^{-1}) \rightarrow L(I^\bullet) \) are quasi-isomorphisms one gets isomorphisms:

\[
\text{Hom}_{K(\Lambda)}(k, I^\bullet) = \text{Hom}_{K(\Lambda)}(k, \sigma^{\geq -1}I^\bullet) \xrightarrow{\sim} \text{Hom}_{D(\Lambda)}(k, \sigma^{\geq -1}I^\bullet) \xleftarrow{\sim}
\]

\[
\sim \xrightarrow{\sim} \text{Hom}_{D(\Lambda)}(k, TZ^{-1}),
\]

\[
\text{Hom}_{D(\Lambda)}(L(k), L(I^\bullet)) \xleftarrow{\sim} \text{Hom}_{D(\Lambda)}(L(k), L(TZ^{-1})).
\]

It follows that it suffices to prove that the map:

\[
\text{Hom}_{D(\Lambda)}(k, TZ^{-1}) \rightarrow \text{Hom}_{D(\Lambda)}(L(k), L(TZ^{-1})))
\]

is an isomorphism of \( k \)-vector spaces. We shall prove that, \( \forall N \in \text{Ob}(\Lambda\text{-mod}) \):

\[
(6.1) \quad \text{Hom}_{D(\Lambda)}(k, T^pN) \xrightarrow{\sim} \text{Hom}_{D(\Lambda)}(L(k), L(T^pN)), \quad \forall p \geq 1.
\]

The proof of (6.1) is based on the following:

Claim: \( \text{Hom}_{D(\Lambda)}(k, T^p(k(a)) \xrightarrow{\sim} \text{Hom}_{D(\Lambda)}(L(k), L(T^p(k(a)))), \quad \forall p \geq 0, \forall a \in \mathbb{Z}.
\]
Assuming the Claim, for the moment, we prove (6.1) by induction on \(\dim_k N\). The initial case \(\dim_k N = 1\) follows from the Claim. For the induction step, let \(a := \min\{i \mid N_i \neq 0\}\). One has an exact sequence: \(0 \to N' \to N \to N'' \to 0\), with \(N'' = N_a \otimes_k \kappa(-a)\). Using the considerations from (2)(i), the induction hypothesis for \(N'\), the Claim for \(N''\) and the Five Lemma one gets immediately (6.1).

Finally, let us prove the Claim. One has:

\[
\text{Hom}_{D(\Lambda)}(k, T^p k(a)) \simeq \text{Ext}^p_{\Lambda\text{-mod}}(k, k(a)),
\]

\[
\text{Hom}_{D(\mathcal{P})}(L(k), L(T^p k(a))) = \text{Hom}_{D(\mathcal{P})}(O_{\mathcal{P}}, T^{p+a}O_{\mathcal{P}}(-a)) \simeq \text{Ext}^{p+a}_{O_{\mathcal{P}}} (O_{\mathcal{P}}, O_{\mathcal{P}}(-a)) \simeq \text{H}^{p+a}O_{\mathcal{P}}(-a).
\]

\(k\) has an injective resolution in \(\Lambda\text{-mod}\):

\[
0 \to k \to \Lambda^\vee \to V^* \otimes_k \Lambda^\vee(1) \to \ldots \to S^i V^* \otimes_k \Lambda^\vee(i) \to \ldots
\]

with differential \(d = \sum_{i=0}^n (X_i \cdot -) \otimes (-e_i)_{\Lambda^\vee}\). It follows that both sides of the Claim are 0 for \(p + a \neq 0\) (assuming, of course, \(p \geq 0\)). It remains to show that:

\[
(6.2) \quad \text{Hom}_{D(\Lambda)}(k, T^p k(-p)) \sim \text{Hom}_{D(\mathcal{P})}(O_{\mathcal{P}}, O_{\mathcal{P}}(p)), \forall p \geq 0.
\]

Consider the morphism (in \(D(\Lambda)\)) \(\varepsilon : k \otimes_k V^* \to T^p k(-1)\) from (3)(b). Since \(L(\varepsilon)\) is the canonical morphism \(O_p \otimes_k V^* \to O_p(1)\), \(L(T^{p-1} \varepsilon(-p + 1))\) is the canonical morphism \(O_p (p - 1) \otimes_k V^* \to O_p(p)\). Using the commutative diagram:

\[
\begin{array}{ccc}
\text{Hom}_{D(\Lambda)}(k, T^{p-1} k(-p + 1) \otimes_k V^*) & \longrightarrow & \text{Hom}_{D(\mathcal{P})}(O_p, O_p(p) \otimes_k V^*) \\
\downarrow & & \downarrow \\
\text{Hom}_{D(\Lambda)}(k, T^p k(-p)) & \longrightarrow & \text{Hom}_{D(\mathcal{P})}(O_p, O_p(p))
\end{array}
\]

one proves easily, by induction on \(p \geq 0\), that the morphism in (6.2) is surjective, hence it is an isomorphism since both sides are isomorphic over \(k\) to \(S^p V^*\). \(\square\)

7. **Theorem.** (Bernstein – Gel’fand – Gel’fand)

(a) *The functor \(L : \Lambda\text{-mod} \to D^b(\text{CohP}(V))\) is essentially surjective.*

(b) *If \(N, N' \in \text{Ob} (\Lambda\text{-mod})\) then the map:

\[
\text{Hom}_{\Lambda\text{-mod}}(N', N) \longrightarrow \text{Hom}_{D^b(\mathcal{P})}(L(N'), L(N))
\]

is surjective and its kernel consists of the morphisms factorizing through a free \((\Leftrightarrow \text{injective})\) object of \(\Lambda\text{-mod}.

**Proof.** We firstly prove the second assertion.

(b) Let \(0 \to N \to I^0 \to I^1 \to \ldots\) be an injective resolution of \(N\) in \(\Lambda\text{-mod}\) and \(\ldots \to I^{-2} \to I^{-1} \to N \to 0\) a free resolution. Glue them in order to get an acyclic complex \(I^*\) consisting of injective \((\Leftrightarrow \text{free})\) objects. By (6)(a), \(L(N) \to L(I^*)\) is
a quasi-isomorphism and by (6)(b) the bottom horizontal arrow of the following commutative diagram:

\[ \begin{array}{ccc}
\mathrm{Hom}_{\Lambda-mod}(N', N) & \longrightarrow & \mathrm{Hom}_{D^b(\mathbb{P})}(L(N'), L(N)) \\
\downarrow & & \downarrow \\
\mathrm{Hom}_{K(\Lambda)}(N', I^\bullet) & \longrightarrow & \mathrm{Hom}_{D^b(\mathbb{P})}(L(N'), L(I^\bullet)) 
\end{array} \]

is an isomorphism. The left vertical arrow of the diagram is surjective and its kernel consists of the morphisms factorizing through \( I^{-1} \).

(a) We observe, firstly, that if \( K^\bullet \in \text{ObC}^b(\Lambda-mod) \) then \( \exists N \in \text{Ob}(\Lambda-mod) \) such that \( L(K^\bullet) \simeq L(N) \) in \( D^b(\mathbb{P}) \). Indeed, consider a quasi-isomorphism \( u : K^\bullet \rightarrow J^\bullet \) (resp., \( v : P^\bullet \rightarrow K^\bullet \)) with \( J^\bullet \in \text{ObC}^+(\Lambda-mod) \) (resp., \( P^\bullet \in \text{ObC}^-(\Lambda-mod) \)) consisting of injective (resp., free) objects. Then \( I^\bullet := \text{Con}(u \circ v) \) is an acyclic complex consisting of injective (\( \Leftrightarrow \) free) objects of \( \Lambda-mod \). Using the short exact sequence:

\[ 0 \rightarrow J^\bullet \rightarrow I^\bullet \rightarrow TP^\bullet \rightarrow 0 \]

and applying (5) to \( TP^\bullet \) one derives that \( L(J^\bullet) \rightarrow L(I^\bullet) \) is a quasi-isomorphism hence \( L(K^\bullet) \rightarrow L(I^\bullet) \) is a quasi-isomorphism. On the other hand, by (6)(a), one has a quasi-isomorphism \( L(Z^0) \rightarrow L(I^\bullet) \). Consequently, \( L(K^\bullet) \simeq L(Z^0) \) in \( D(\mathbb{P}) \).

Let now \( \mathcal{F}^\bullet \in \text{ObC}^b(\text{Coh}(\mathbb{P}(V))) \). Let \( p := \max\{i \in \mathbb{Z} \mid \mathcal{F}^i \neq 0\} \) and let \( u : \sigma^\leq_p \mathcal{F}^\bullet \rightarrow T^{-p+1} \mathcal{F}^p \) be the morphism defined by \( d_{\mathcal{F}}^{p-1} : \mathcal{F}^{p-1} \rightarrow \mathcal{F}^p \). Then \( \mathcal{F}^\bullet = \text{Con}(u) \). Assume there exist \( N', N'' \in \text{Ob}(\Lambda-mod) \) and isomorphisms in \( D^b(\mathbb{P}) \)

\[ \psi : L(N'') \xrightarrow{\sim} \sigma^\leq_p \mathcal{F}^\bullet, \quad \varphi : L(N') \xrightarrow{\sim} T^{-p+1} \mathcal{F}^p \].

By (b), \( \exists f \in \text{Hom}_{\text{Ob}(\Lambda-mod)}(N'', N') \) such that \( L(f) = \varphi^{-1} \circ u \circ \psi \). Then \( \mathcal{F}^\bullet \simeq L(\text{Con}(f)) \) in \( D^b(\mathbb{P}) \), hence, by the above observation, \( \exists N \in \text{Ob}(\Lambda-mod) \) such that \( \mathcal{F}^\bullet \simeq L(N) \).

By induction on the length of \( \mathcal{F}^\bullet \), one can now reduce the proof to the case when \( \mathcal{F}^\bullet \) has only one non-zero term. By Serre’s results from [6], any coherent sheaf on \( \mathbb{P}(V) \) has a finite resolution with finite direct sums of invertible sheaves \( \mathcal{O}_\mathbb{P}(a) \). By induction on the length of this resolution, one reduces the proof, as above, to the case when \( \mathcal{F}^\bullet = T^p \mathcal{O}_\mathbb{P}(a) \). But \( T^p \mathcal{O}_\mathbb{P}(a) = L(T^{p+a}k(-a)) \). □

8. Corollary. ([2] Remark 3 after Theorem 1)

For every \( \mathcal{F}^\bullet \in \text{ObC}^b(\text{Coh}(\mathbb{P}(V))) \) there exists \( N \in \text{Ob}(\Lambda-mod) \) annihilated by \( \text{soc}(\Lambda) \) such that \( \mathcal{F}^\bullet \simeq L(N) \) in \( D^b(\text{Coh}(\mathbb{P}(V))) \). Moreover, \( N \) is unique up to isomorphism.

Proof. The existence of \( N \) follows from (7)(a) and (4)(iv). Let \( N' \) be another such \( \Lambda \)-module. By (7)(b), there exists a morphism \( u : N' \rightarrow N \) in \( \Lambda-mod \) such that \( L(u) : L(N') \rightarrow L(N) \) is an isomorphism in \( D^b(\mathbb{P}) \) (i.e., it is a quasi-isomorphism).

By (7)(b) again, there exists \( v : N \rightarrow N' \) such that \( L(v) \) is the inverse of \( L(u) \) in \( D^b(\mathbb{P}) \). By the last part of (7)(b), there exists a free object \( P \) of \( \Lambda-mod \) such that \( id_N - u \circ v \) factorizes as \( N \xrightarrow{f} P \xrightarrow{g} N \).

The submodule of \( P \) consisting of the elements annihilated by \( \text{soc}(\Lambda) \) is \( P \cdot \Lambda_+ \), hence \( f(N) \subseteq P \cdot \Lambda_+ \), hence \( \text{Im}(id_N - u \circ v) \subseteq N \cdot \Lambda_+ \). Using the exterior algebra version of the graded NAK, one derives that \( u \circ v \) is surjective, hence it is an
isomorphism because \( N \) is a finite dimensional \( k \)-vector space. Similarly, \( v \circ u \) is an isomorphism. Consequently, \( u \) is an isomorphism. \( \square \)

9. **Definition.** Let \( N \in \text{Ob}(\Lambda \text{-mod}) \) annihilated by \( \text{soc}(\Lambda) \). Consider a minimal free resolution of \( N \) in \( \Lambda \text{-mod} : \ldots \to I^{-2} \to I^{-1} \to N \to 0 \). Minimality is equivalent to the condition : \( \text{Im}(I^{-p-1} \to I^{-p}) \subseteq I^{-p} \cdot \Lambda_+ \), \( \forall p \geq 1 \). Consider also an injective resolution of \( N \) in \( \Lambda \text{-mod} : 0 \to N \to I^0 \to I^1 \to \ldots \) such that \( \text{Im}(I^p \to I^{p+1}) \subseteq I^{p+1} \cdot \Lambda_+ \), \( \forall p \geq 0 \). To get such a resolution, take a minimal free resolution of \( N^\vee \) and dualize it. Glueing the two resolutions one gets an acyclic complex \( I^\bullet \) consisting of injective \((\Leftrightarrow \text{free})\) objects of \( \Lambda \text{-mod} \) such that \( \text{Im}d^p_I \subseteq I^{p+1} \cdot \Lambda_+ \), \( \forall p \in \mathbb{Z} \) (for \( p = -1 \) this follows from the fact that \( N \cdot \text{soc}(\Lambda) = (0) \)).

Such a complex \( I^\bullet \) is called a *Tate resolution* of \( N \).

10. **Theorem.** (Eisenbud – Flenstad – Schreyer)

Let \( F^\bullet \in \text{Ob}C^b(\text{Coh}(\mathbb{P}(V))) \), let \( N \) be the unique (up to isomorphism) object of \( \Lambda \text{-mod} \) annihilated by \( \text{soc}(\Lambda) \) with \( F^\bullet \simeq L(N) \) in \( D^b(\text{Coh}(\mathbb{P}(V))) \) and let \( I^\bullet \) be a Tate resolution of \( N \). Then:

(a) \( I^p \simeq \bigoplus_i \mathbb{H}^{p-i}F^\bullet(i) \otimes_k \Lambda^\vee(i), \forall p \in \mathbb{Z} \) (where \( \mathbb{H} \) denotes hypercohomology),

(b) \( d^p_I : I^p \to I^{p+1} \) maps \( \mathbb{H}^{p-i}F^\bullet(i) \otimes_k \Lambda^\vee(i) \) to \( \bigoplus_j \mathbb{H}^{p+1-j}F^\bullet(j) \otimes_k \Lambda^\vee(j) \) and the component : \( \mathbb{H}^{p-i}F^\bullet(i) \otimes_k \Lambda^\vee(i) \to \mathbb{H}^{p-i}F^\bullet(i+1) \otimes_k \Lambda^\vee(i+1) \) of \( d^p_I \) is defined (see (4)(i)) by the multiplication map : \( \mathbb{H}^{p-i}F^\bullet(i) \otimes_k V^* \to \mathbb{H}^{p-i}F^\bullet(i+1) \) (up to sign).

**Proof of (10)(a).** (according to Remark 3 after Theorem 2 in [2]).

If \( I^p \simeq \bigoplus_i \Lambda^\vee(i) \gamma^p_i \) then \( \text{soc}(I^p) \simeq \bigoplus_i k(i) \gamma^p_i \). Taking into account that \( \text{Im}d^p_I \subseteq I^{q+1} \cdot \Lambda_+ \), \( \forall q \in \mathbb{Z} \), one gets that:

\[
\text{soc}(I^p)_{-i} \simeq \text{Hom}_{\Lambda \text{-mod}}(k, I^p(-i)) \simeq \text{Hom}_{K(\Lambda)}(k, T^p I^\bullet(-i)).
\]

On the other hand, by (6):

\[
\text{Hom}_{K(\Lambda)}(k, T^p I^\bullet(-i)) \simeq \text{Hom}_{D(\mathbb{P})}(\mathcal{O}_\mathbb{P}, T^{p-i}F^\bullet(i)) \simeq \mathbb{E}xt^{p-i}(\mathcal{O}_\mathbb{P}, F^\bullet(i)) \simeq \mathbb{H}^{p-i}F^\bullet(i). \quad \square
\]

For the proof of (10)(b) we need the following addendum to (2)(iii):

11. **Remark.** Under the assumptions of (2)(iii), let \( w : Z^\bullet \to TX^\bullet \) be the morphism in \( D^+(\mathcal{A}) \) defined in (2)(i). Then:

\[
\text{Hom}_{K(\mathcal{A})}(T^{-1}w, \text{id}_{T^p I}) : \text{Hom}_{K(\mathcal{A})}(X^\bullet, T^p I^\bullet) \to \text{Hom}_{K(\mathcal{A})}(T^{-1}Z^\bullet, T^p I^\bullet)
\]

equals \((-1)^p \partial^p \) where \( \partial^p : \text{Hom}_{K(\mathcal{A})}(X^\bullet, T^p I^\bullet) \to \text{Hom}_{K(\mathcal{A})}(Z^\bullet, T^{p+1} I^\bullet) \) is the “classical” connecting morphism associated to the short exact sequence of complexes of abelian groups:

\[
0 \to \text{Hom}^\bullet(Z^\bullet, I^\bullet) \to \text{Hom}^\bullet(Y^\bullet, J^\bullet) \to \text{Hom}^\bullet(X^\bullet, I^\bullet) \to 0.
\]
Proof. \( \partial^p \) is defined as follows: let \( f : X^\bullet \to T^p I^\bullet \) be a morphism of complexes. Lift every \( f^i : X^i \to I^{i+p} \) to a morphism \( g^i : Y^i \to I^{i+p} \). Then the morphism of complexes \( (d_I^{i+p} \circ g^i - (-1)^p g^{i+1} \circ d_Y^i)_i \in \mathbb{Z} : Y^\bullet \to T^{p+1} I^\bullet \) vanishes on \( X^\bullet \) hence induces a morphism of complexes \( \partial^p(f) : Z^\bullet \to T^{p+1} I^\bullet \) (in fact, to be rigorous, one has to take homotopy classes).

We have to prove that the diagram:

\[
\begin{array}{c}
T^{-1} \text{Con}(u) \quad \xrightarrow{(id_X, 0)} \quad X^\bullet \\
(0, T^{-1} v) \downarrow \quad \Downarrow f \\
T^{-1} Z^\bullet \quad \xrightarrow{(-1)^p T^{-1} \partial^p(f)} \quad T^p I^\bullet
\end{array}
\]

is homotopically commutative. One can use the homotopy operators \( h^i := (0, g^{i-1}) : (T^{-1} \text{Con}(u))^i = X^i \oplus Y^{i-1} \to I^{i+p-1} = (T^p I^\bullet)^{i-1} \).

Proof of (10)(b). The first assertion follows from the fact that \( \text{Im} d_I^p \subseteq I^{p+1} \Lambda_+ \). For the second assertion we consider the morphism (in \( D^b(\Lambda \text{-mod}) \)) \( \nu : T^{-1} k(1) \to k \otimes_k V \) from (3)(a). By (6), the map:

\[
\text{Hom}_{K(\Lambda)}(\nu, \text{id}) : \text{Hom}_{K(\Lambda)}(k \otimes_k V, T^p I^\bullet(-i)) \longrightarrow \text{Hom}_{K(\Lambda)}(T^{-1} k(1), T^p I^\bullet(-i))
\]

can be identified to the map:

\[
\text{Hom}_{D(\mathbb{P})}(L(\nu), \text{id}) : \text{Hom}_{D(\mathbb{P})}(O_{\mathbb{P}} \otimes_k V, T^{p-i} F^\bullet(i)) \longrightarrow \text{Hom}_{D(\mathbb{P})}(O_{\mathbb{P}}(-1), T^{p-i} F^\bullet(i))
\]

and this one can be identified to the multiplication map:

\[
\mathbb{P}^{p-i} F^\bullet(i) \otimes_k V^* \longrightarrow \mathbb{P}^{p-i} F^\bullet(i+1).
\]

We want now to explicitate \( \text{Hom}_{K(\Lambda)}(\nu, \text{id}) \). Let \( \xi \in \mathbb{P}^{p-i} F^\bullet(i), \lambda \in V^* \) and let \( f : k \otimes_k V \to I^p(-i) \) be the morphism defined by \( \xi \otimes \lambda : k \otimes_k V \to \mathbb{P}^{p-i} F^\bullet(i) \otimes_k (\Lambda^\vee)_0 \). Then \( f \) can be lifted to the morphism \( g : (\Lambda/(\Lambda_+)^2(1) \to I^p(-i) \) sending \( I \in (\Lambda/(\Lambda_+)^2)_{-1} \) to \( \xi \otimes \lambda \in \mathbb{P}^{p-i} F^\bullet(i) \otimes_k (\Lambda^\vee)_{-1} \).

Using (11) and the explicit description of \( \partial^p \) from its proof) one derives that \( \text{Hom}_{K(\Lambda)}(\nu, \text{id}) \) can be identified to:

\[
(-1)^{p-1} d_I^p | \mathbb{P}^{p-i} F^\bullet(i) \otimes_k \Lambda^{\vee}(-i-1) \longrightarrow \mathbb{P}^{p-i} F^\bullet(i+1) \otimes_k \Lambda^{\vee}(i+1) \rightarrow 1.
\]

One can easily deduce from (10) the Lemma of Castelnuovo-Mumford. More important, Eisenbud et al.[3] show that (10) implies the results of A.A. Beilinson [1]. We close the paper by briefly explaining this, in terms of the present approach.

12. Theorem. (Beilinson) Let \( F^\bullet \in \text{Ob} C^b(\text{Coh}\mathbb{P}(V)) \). Then \( F^\bullet \) is isomorphic in \( D^b(\text{Coh}\mathbb{P}(V)) \) to a complex \( C^\bullet \) with \( C^p = \bigoplus_i \mathbb{P}^{p+i} F^\bullet(-i) \otimes_k \Omega_{\mathbb{P}}^i(i), \forall p \in \mathbb{Z} \) and also to a complex \( C'^\bullet \) with \( C'^p = \bigoplus_i O_{\mathbb{P}}(-i) \otimes_k \mathbb{P}^{p+i}(F^\bullet \otimes \Omega_{\mathbb{P}}^i(i)), \forall p \in \mathbb{Z} \).

Proof. (according to [3] (6.1) and (8.11)).
Let $N$ and $I^\bullet$ be as in the statement of (10). Recall, from (6)(a), that $L(N) \rightarrow L(I^\bullet)$ is a quasi-isomorphism. By definition, $L(I^\bullet) = s(X^{\bullet\bullet})$ for a certain double complex $X^{\bullet\bullet}$ with $X^{pq} = O_\mathbb{P}(q) \otimes_k I^p_\mathbb{P}$.

(I) In order to prove the first assertion, one takes $C^\bullet := Ker(X^{\bullet,0} \rightarrow X^{\bullet,1})$. Taking into account that $Ker(L(\Lambda^\vee(-i))^0 \rightarrow L(\Lambda^\vee(-i))^1) = \Omega_{\mathbb{P}}^i(i)$, the formula for $C^p$ follows from (10)(a).

It remains to show that $C^\bullet \rightarrow s(X^{\bullet\bullet})$ is a quasi-isomorphism. It decomposes as $C^\bullet \rightarrow s(\sigma_{II}^{\geq 0} X^{\bullet\bullet}) \rightarrow s(X^{\bullet\bullet})$, where $(\sigma_{II}^{\geq 0} X^{\bullet\bullet})_{ij} := X_{ij}$ for $j \geq 0$ and $= 0$ for $j < 0$. Since the columns of $X^{\bullet\bullet}$ are acyclic, $C^\bullet \rightarrow s(\sigma_{II}^{\geq 0} X^{\bullet\bullet})$ is a quasi-isomorphism. On the other hand, one has a short exact sequence:

$$0 \rightarrow s(\sigma_{II}^{\geq 0} X^{\bullet\bullet}) \rightarrow s(X^{\bullet\bullet}) \rightarrow s(\sigma_{II}^{< 0} X^{\bullet\bullet}) \rightarrow 0$$

hence it suffices to prove that $s(\sigma_{II}^{< 0} X^{\bullet\bullet})$ is acyclic.

For $p \in \mathbb{Z}$, let $a(p) := \min\{q \in \mathbb{Z} \mid I^p_\mathbb{P} \neq 0\}$. Since $I^{p-1} \rightarrow I^p \rightarrow \mathbb{Z}^{p+1} \rightarrow 0$ is a minimal free presentation, it follows that $a(p-1) > a(p)$, $\forall p \in \mathbb{Z}$. One deduces that the rows of $X^{\bullet\bullet}$ are bounded to the left.

Now, $s(\sigma_{II}^{< 0} X^{\bullet\bullet})$ is the direct limit of the complexes $s(\sigma_{II}^{< p} \sigma_{II}^{\geq 0} X^{\bullet\bullet})$ for $p \geq 1$. But $\sigma_{II}^{< p} \sigma_{II}^{\geq 0} X^{\bullet\bullet}$ is a “first quadrant” type double complex with acyclic rows hence its associated simple complex is acyclic.

(II) Let us prove the second assertion. One takes the subcomplex $J^\bullet$ of $I^\bullet$ defined by $J^p := \bigoplus_{i \geq 0} \mathbb{H}^{p-i} F^\bullet(i) \otimes_k \Lambda^\vee(i)$. One has $J^p = 0$ for $p << 0$ and $J^p = I^p$ for $p >> 0$ hence, by (5), $L(J^\bullet) \rightarrow L(I^\bullet)$ is a quasi-isomorphism.

Now, $L(J^\bullet) = s(Y^{\bullet\bullet})$ for a certain double complex $Y^{\bullet\bullet}$ with splitting rows $Y^{\bullet,q}$, $q \in \mathbb{Z}$ and with columns $Y^{p,\bullet} = L(J^p) = 0$, for $p << 0$. According to a general lemma about such double complexes (see [3] (3.5)), $s(Y^{\bullet\bullet})$ is homotopically equivalent to a complex $C^{\bullet\bullet}$ whose “linear part” is $L(H^\bullet(J^\bullet))$ (where $H^\bullet(J^\bullet)$ is the complex with $p$th term $H^p(J^\bullet)$ and with all the differentials equal to 0). In particular: $C^{\bullet,p} \simeq \bigoplus_i O_{\mathbb{P}}(-i) \otimes_k H^{p+i}(J^\bullet)_{-i}$. But $J^\bullet_{-i} = 0$ for $i < 0$ and $J^\bullet_{-i} = I^\bullet_{-i}$ for $i > n$ hence (since $I^\bullet$ is acyclic) $H^q(J^\bullet)_{-i} = 0$ for $i < 0$ and for $i > n$, $\forall q \in \mathbb{Z}$.

On the other hand, for $0 \leq i \leq n$ and $q \in \mathbb{Z}$ : $J^q_{-i} \simeq Hom_{\Lambda^\text{-mod}}((\Lambda/(\Lambda^+_i)^{i+1})^{\bullet}(i), I^q)$ hence $H^q(J^\bullet)_{-i} \simeq Hom_{K(\Lambda)}((\Lambda/(\Lambda^+_i)^{i+1})^{\bullet}(i), T^q I^\bullet)$. One can now apply (6), taking into account that $L((\Lambda/(\Lambda^+_i)^{i+1})^{\bullet}(i)) \simeq (\Omega_{\mathbb{P}}^i(i))^*$ in $D^b(\mathbb{P})$. \hfill \Box
