The suppressor of cytokine signaling (SOCS) proteins are negative regulators of the JAK/STAT pathway activated by proinflammatory cytokines, including the tumor necrosis factor-α (TNF-α). SOCS3 is also implicated in hypertriglyceridemia associated to insulin resistance. Proprotein convertase subtilisin kexin type 9 (PCSK9) levels are frequently found to be positively correlated to insulin resistance and plasma very low density lipoprotein (VLDL) triglycerides concentrations. The present study aimed to investigate the possible role of TNF-α and JAK/STAT pathway on de novo lipogenesis and PCSK9 expression in HepG2 cells. TNF-α induced both SOCS3 and PCSK9 in a concentration-dependent manner. This effect was inhibited by transfection with siRNA anti-STAT3, suggesting the involvement of the JAK/STAT pathway. Retroviral overexpression of SOCS3 in HepG2 cells (HepG2-SOCS3) strongly inhibited STAT3 phosphorylation and induced PCSK9 mRNA and protein, with no effect on its promoter activity and mRNA stability. Consistently, siRNA anti-SOCS3 reduced PCSK9 mRNA levels, whereas an opposite effect was observed with siRNA anti-STAT3. In addition, HepG2-SOCS3 express higher mRNA levels of key enzymes involved in the de novo lipogenesis, such as fatty-acid synthase, stearoyl-CoA desaturase (SCD)-1, and apoB. These responses were associated with a significant increase of SCD-1 protein, activation of sterol regulatory element-binding protein-1c (SREBP-1), accumulation of cellular triglycerides, and secretion of apoB. HepG2-SOCS3 show lower phosphorylation levels of insulin receptor substrate 1 (IRS-1) Tyr416 and Akt Ser473 in response to insulin. Finally, insulin stimulation produced an additive effect with SOCS3 overexpression, further inducing PCSK9, SREBP-1, fatty acid synthase, and apoB mRNA. In conclusion, our data candidate PCSK9 as a gene involved in lipid metabolism regulated by proinflammatory cytokine TNF-α in a SOCS3-dependent manner.

The family of suppressor of cytokine signaling (SOCS)2 consists of eight members (SOCS-1 to SOCS-7 and cytokine-inducible SH2 protein (CIS)) all sharing a central SH2 domain and a C-terminal SOCS box. Expression of CIS, SOCS-1, SOCS-2, and SOCS-3 is induced by various cytokines, including IL-6 and tumor necrosis factor-α (TNF-α) (1), and has been implicated in the negative regulation of several pathways, particularly the Janus kinase (JAK) signal transducer and activator of transcription (STAT) one (2). SOCS proteins are highly and selectively induced in a tissue-specific manner by a diverse range of stimuli other than the classical activators of the JAK/STAT pathway, including insulin (3), leptin (4), and resistin (5). In obesity, the expression of SOCS proteins is elevated in a variety of tissues that are vital for regulating fatty acid (FA) metabolism and insulin sensitivity. For instance, SOCS1 and SOCS3 are up-regulated in the liver of obese diabetic db/db mice and other insulin resistance (IR) models such as ob/ob mice and mice fed high fat diet (6, 7). The functional role of SOCS3 on hepatic steatosis and hyperlipidemia was also demonstrated by using SOCS antisense approach. The latter reduced in db/db mice the elevated hepatic lipid content and plasma triglycerides close to the normal observed in control mice (7). Furthermore, liver of morbidly obese subjects exhibits higher expression of SOCS3 protein and attenuated JAK/STAT signaling, resulting in enhanced sterol regulatory element-binding protein-1c (SREBP-1c) transcriptional activity, a key regulator of de novo lipid biosynthesis (8). This evidence might suggest that the inhibition of JAK/STAT pathway by SOCS3 is mechanistically related to the development of hepatic IR and dyslipidemia in humans.

Proprotein convertase subtilisin kexin type 9 (PCSK9) belongs to the proprotein convertase family (9). Genetic and, more recently, pharmacological studies have clearly demon-

2 The abbreviations used are: SOCS3, suppressor of cytokine signaling; FA, fatty acid; FAS, fatty acid synthase; IR, insulin resistance; HMG-CoA, 3-hydroxy-3-methylglutaryl coenzyme; HNF, hepatocyte nuclear factor; LDL, low density lipoprotein cholesterol; PCSK9, proprotein convertase subtilisin kexin type 9; SREBP, sterol regulatory element-binding protein; SRE, sterol regulatory element; SCD, stearoyl-CoA desaturase; TG, triglycerides; WB, Western blot; qPCR, quantitative PCR; LDLR, LDL receptor; LPDS, lipoprotein plasma-deprived serum; TEMED, N,N,N’,N’-tetramethyldiamine; Bis-Tris, 2-(bis[2-hydroxyethyl]amino)-2-(hydroxyethyl)propane-1,3-diol; ANOVA, analysis of variance; MEM, minimum Eagle’s medium.
stratified its involvement in the regulation of low density lipoprotein cholesterol (LDL) levels by inducing the degradation of the LDL receptor (LDLr) in a manner independent from its proteolytic activity (10–13). Similarly to the genes involved in the regulation of the cholesterol homeostasis, i.e. hydroxymethylglutaryl-CoA reductase and synthase and the LDLr, PCSK9 is under the control of the SREBP-2 (14). For this reason the pharmacological activation of the SREBP pathway by HMG-CoA reductase inhibitors, statins, induces PCSK9 both in experimental and clinical settings (15–17). Although SREBP-1a and SREBP-1c preferentially activate genes involved in the synthesis of fatty acids and triglycerides, their homologous SREBP-2 preferentially transcribes for genes involved in the cholesterol biosynthetic pathway (18, 19). To this regard, PCSK9 appears to be regulated by both SREBP-2 and SREBP-1c (14, 20), where the latter mediates the induction of PCSK9 in response to insulin (14, 21–23). The involvement of SREBP-1c in the regulation of PCSK9 levels has also been observed in humans, where PCSK9 levels positively correlated with IR, liver steatosis, and very low density lipoprotein (VLDL-TG) triglycerides (TG) (24).

This evidence suggests that, although PCSK9 is an important regulator of LDL-C levels, it could also be implicated in the homeostasis of TG-rich lipoproteins. It is, indeed, of interest that the association between plasma PCSK9 and LC-DL-C is weak and has been estimated to account for only the 7% of the variations in LDL-C (25), whereas PCSK9 levels are more significantly associated with plasma concentrations of TG, glucose, and insulin (21, 25–27). Based on these premises, the present study aimed to investigate the possible role of TNF-α and JAK/STAT pathway on de novo lipogenesis and PCSK9 expression in the human HepG2 cell line.

**Experimental Procedures**

**Cell Cultures**—The human hepatocellular liver carcinoma cell line, HepG2, was cultured in 10% FCS/MEM supplemented with penicillin (10,000 units/ml), streptomycin (10 mg/ml), nonessential amino acids, and sodium pyruvate. For the experiments, cells were incubated with MEM containing either 10% of lipoprotein plasma-deprived serum (LPDS) or 10% fetal calf serum (FCS) as indicated in the figures legend.

**Reagents and Antibodies**—MEM, trypsin EDTA, penicillin, streptomycin, nonessential amino acid solution, FCS, disposable culture flasks, and Petri dishes were from Euroclone (Pero, Milan, Italy), and filters were from Millipore (Billerica, MA). Molecular weight protein standards were from Bio-Rad. SDS, TEMED, ammonium persulfate, glycine, and acrylamide solution (30% T, 2.6% C) were obtained from Bio-Rad. BCA assay for determination of protein concentrations was purchased from Thermo Fischer Scientific (Waltham, MA). [14C]Acetate for determination of protein concentrations was purchased from Amersham Biosciences. Recombinant insulin, TNF-α, and bovine serum albumin (BSA) were purchased from Sigma. STAT3 inhibitor, MD77, was kindly provided by Prof. Daniela Barlocco (Università degli Studi di Milano, Milan, Italy) 31. The JAK inhibitor JAK1 was purchased from Millipore (Milipore, Milan, Italy). Actinomycin D was purchased from DharmaconTM (Carlo Erba Reagents, Milan, Italy). Transfections were performed as previously described (28, 29). A polyclonal population of HepG2 control and SOCS3-overexpressing cells has been then selected with 10 μg/ml puromycin.

**Transfection of siRNA—ON-TARGET plus SMART pool siRNA directed to STAT3 and SOCS3 or scramble control were purchased from Dharmacon™ (Carlo Erba Reagents, Milan, Italy). Transfections were performed as previously described using SilentFect™ Lipid Reagent (Bio-Rad) according to the manufacturer’s protocol (30, 31). HepG2 cells were seeded at a density of 6 × 10^5/well (6 well tray) the day before the transfection in completed medium. Cells were then transfected with 20 nm siRNA for 48 h, then the medium was replaced with MEM containing 5% LPDS ± TNF-α for an additional 24 h before performing the quantitative real time PCR (qPCR) or WB analysis.

**Synthesis of Total Cholesterol**—Cholesterol biosynthesis was estimated by measuring the incorporation of [14C]acetate into cellular cholesterol, as previously described (32).

**Evaluation of Intracellular TG and Cholesterol Levels**—Total cellular lipids were extracted with hexane/isopropyl alcohol 3:2, and TG and cholesterol contents were determined with enzymatic assays (HORIBA ABX, Montpellier, France).

**ELISA Assay**—Conditioned media was cleared by centrifugation (13,000 rpm for 10 min) and store at −20°C. The amount of apolipoprotein B (apoB) (Vinci-Biochem, Firenze, Italy) and PCSK9 (R&D System, Minneapolis, MN) was then quantified by using the ELISA assays according to manufacturer’s instruc-
Grant Support—This work was supported in part by Grants R01HL060174 and P30DK052564 from the National Institutes of Health, and by Grants 31-6767 and 31-6767/2-4 from the Swiss National Science Foundation. Analysis of the Data—Statistical analysis was performed using the Prism statistical analysis package (GraphPad Software, San Diego, CA). Data are given as the mean ± S.D. of three independent experiments. When possible, p values were determined by Student’s t test. Otherwise, differences between treatment groups were evaluated by one-way ANOVA. A probability value of p < 0.05 was considered statistically significant.

Results

TNF-α Induced SOCS3 and PCSK9 in HepG2 Cells—Release of proinflammatory cytokines such as TNF-α and IL-6 from adipocytes of obese subjects with IR has been shown to activate the JAK/STAT pathway at the hepatic levels and induce, either directly or indirectly, the transcription of different target genes including SOCS proteins (6, 7). In agreement with these observations we found that the incubation of hepatic cell line HepG2 with TNF-α induced the expression of SOCS3 mRNA in a time- and concentration-dependent manner (Fig. 1A), reaching the maximal induction after 24 h of incubation at the concentration of 10 ng/ml. This latter resulted in 3-fold induction of SOCS3 protein, evaluated by WB analysis (Fig. 1A). Under the same experimental conditions, TNF-α induced both PCSK9 mRNA, although to lower extent (Fig. 1B), and PCSK9 protein (∼+41%), as determined by WB analysis (Fig. 1B). Transfection of HepG2 cells with specific siRNA significantly down-regulated protein expression of STAT3 and SOCS3 (Fig. 1C). siRNA STAT3 com-
Completely blocked the induction of SOCS3 by TNF-α (Fig. 1D). A similar effect was observed on the expression levels of PCSK9, where siRNA to either SOCS3 or STAT3 blocked the effect of TNF-α (Fig. 1E). These results suggest the possibility that TNF-α induces PCSK9 by inducing the SOCS3 expression.

**SOCS3 Overexpression Induced PCSK9 in HepG2—**To further investigate the role of SOCS3 on PCSK9 expression, we generated a retrovirally transduced HepG2 cell line with a plasmid encoding human SOCS3 (HepG2SOCS3). After puromycin selection, the mRNA and protein overexpression of exogenous human SOCS3 were evaluated by qPCR and WB analyses, respectively. HepG2SOCS3 cells were compared with HepG2 transduced with empty retroviral vector encoding only the puromycin resistance gene. As shown in Fig. 2A, retroviral transduction determined ~90-fold induction of mRNA of SOCS3 that translated into a 70% increase of protein SOCS3 (Fig. 2B). The overexpression of SOCS3 abrogated basal STAT3 phosphorylation state (Fig. 2C).

HepG2SOCS3 cells show higher levels of PCSK9 mRNA (3.48 ± 0.35-fold; Fig. 2D) and increased amounts of cellular and secreted PCSK9 (1.53-fold and 2.18 ± 0.38-fold, respectively; Fig. 2E and F). Because SOCS3 has been shown to be up-regulated in animal models of obesity (6), we then evaluated the mRNA levels of PCSK9 and SOCS3 in the liver of ob/ob and wild-type C57BL/6 control mice. The ob/ob mice expressed higher levels of SOCS3 (6.46 ± 4.8-fold), and this condition was associated with a significant induction of PCSK9 (2.03 ± 1.54-fold) (Fig. 2G and H). The inhibition of SOCS3 and STAT3 by siRNA resulted in an opposite effect on PCSK9 mRNA levels, with a significant reduction after transfection with siRNA SOCS3 and an induction with siRNA STAT3 (Fig. 2I).

We then investigated the effect of SOCS3 on PCSK9 promoter activity in HepG2 and HepG2SOCS3 transfected with the luciferase reporter construct pGL3-PCSK9-D4 (33). This plasmid contains the 5′-flanking region of the PCSK9 gene, from nucleotide −440 to −94 (relative to the ATG start codon), in

**FIGURE 1.** TNF-α induced SOCS3 and PCSK9 in HepG2 cells. A and B, HepG2 cells were seeded in MEM, 10% FCS and the day after incubated with MEM supplemented with 10% LPDS for 6 h and 24 h in the presence or absence of different concentrations of TNF-α (0.1, 1, and 10 ng/ml). At the end of the incubation the total RNA was extracted, and mRNA levels of SOCS3 and PCSK9 were determined by qPCR. Insets of panels A and B SOCS3 and PCSK9 protein expression were evaluated by WB analysis from total protein extracts of HepG2 cells incubated for 24 h with 10 ng/ml TNF-α. α-Tubulin was used as loading control. C, HepG2 cells were seeded in MEM, 10% FCS and the day after transfected with siRNA scramble, STAT3, and SOCS3. After 48 h the medium was replaced with MEM with 10% LPDS. After an additional 24 h the protein expression of STAT3 and SOCS3 and α-tubulin were evaluated by WB analysis. D and E, cells were incubated under the same experimental conditions described for panels A and B in the presence or absence of 10 ng/ml TNF-α during the last 24 h of incubation in MEM with 10% LPDS. At the end of the incubation the total RNA was extracted, and mRNA levels of SOCS3 and PCSK9 were determined by qPCR. Differences between treatments were assessed by Student’s t test and one-way ANOVA (when necessary): *, p < 0.05; **, p < 0.01; ***, p < 0.001.
front of the luciferase coding sequence. The relative luciferase activity of the PCSK9 promoter was not affected by the expression of SOCS3 in HepG2 cells (Fig. 2L). A similar response was observed by using the D4 construct containing the mutation of sterol regulatory element (SRE), whereas the mutation of HNF-1 site determined a significant increase of the promoter activity in HepG2SOCS3 cells, although the overall transcriptional activity was almost abolished (Fig. 2L).

To further investigate the effect of SOCS3 on PCSK9 mRNA induction, we determined the involvement of the SREBP factors by incubating HepG2 with 25-OH cholesterol (inhibitor of both SREBP-1 and SREBP-2) (32) or fatostatin (a more selective inhibitor of SREBP-1) (35). As shown in Fig. 3A, 25-OH cholesterol completely down-regulated the PCSK9 mRNA levels in both HepG2 and HepG2SOCS3. On the contrary, fatostatin affected exclusively the induction of PCSK9 in HepG2SOCS3 (Fig. 3B). SOCS3 overexpression induced the processing from the precursor to the active form of SREBP-1 (Fig. 3C). The activation of SREBP-2 was inhibited, with the accumulation of its precursor and a reduction of the active form (Fig. 3C). In addition, HNF-1α protein (54%) and mRNA levels (2.87 ± 0.98-fold) were significantly induced in SOCS3-overexpressing cells (Fig. 3C and D). The incubation with the transcriptional activity inhibitor, actinomycin D, showed that in HepG2SOCS3 the stability of PCSK9 mRNA was not affected compared with HepG2 (Fig. 3L). Taken together, these results suggest that the PCSK9 induction in response to SOCS3 overexpression is mainly mediated by a transcriptional-regulated process.

Pharmacological Inhibition of JAK/STAT Pathway Induced PCSK9—To further investigate the effect of STAT3 inhibition on PCSK9 expression, HepG2 cells were incubated with non-toxic concentration of STAT3-inhibitor MD77 (Fig. 4) (36).
Incubation of HepG2 cells for 48 h with 10^{-7} M MD77 determined very similar cellular responses from those observed with SOCS3 overexpression. In particular, incubation with MD77 induced fatty acid synthase (FAS; 2.93 ± 1.28-fold; Fig. 4A), PCSK9 (2.06 ± 0.7-fold; Fig. 4B) and, only marginally, HMG-CoA reductase (1.58 ± 0.2-fold; Fig. 4C) with a not statistically significant reduction of LDLR (∼45.3 ± 24.7%; Fig. 4D). The JAK inhibitor, JAK1, significantly increased FAS (1.56 ± 0.05-fold; Fig. 4E), PCSK9 (3.30 ± 0.32-fold; Fig. 4F), and HMG-CoA reductase (1.49 ± 0.09-fold; Fig. 4G) and marginally reduced the LDLR (∼43.2 ± 24.2%; Fig. 4H). Consistent with the results with HepG2^SOCS3, no effect on PCSK9 promoter activity was observed after 24 h of incubation with JAK1 (Fig. 4I). Taken together, these results demonstrate that the inhibition of the JAK/STAT pathway induces PCSK9 in HepG2 cells.

**SOCS3 Overexpression Induced de Novo Lipogenesis in HepG2 Cells**—In vivo evidence demonstrated the pivotal role of SOCS3 and STAT3 on lipid metabolism and SREBP-1 transcriptional activity (6, 7, 37). To verify that a similar response also occurs in our experimental model, we determined the mRNA levels of SREBP-1 target genes, such as FAS and SCD-1 and the levels of apoB. HepG2^SOCS3 cells showed higher mRNA levels of FAS (3.59 ± 0.40-fold; Fig. 5A) as well as that of SCD-1 gene (1.92 ± 0.12-fold; Fig. 5B) and protein (3.81 ± 0.75-fold; Fig. 5C). Together with these changes, we observed a significant increment of apoB mRNA (4.08 ± 0.41-fold; Fig. 5D) and protein in the conditioned media (3.47 ± 0.09-fold; Fig. 5E). Accumulation of intracellular TG levels (22.1 ± 7.1 μg/mg of protein versus 38.3 ± 9.1 μg/mg of protein; Fig. 5F) was seen in HepG2^SOCS3, with no significant changes in total cholesterol content (Fig. 5G).

In response to TNF-α, we observed a significant induction of SCD-1, apoB, and FAS mRNA levels (2.11 ± 0.43, 1.60 ± 0.33, and 1.39 ± 0.21-fold, respectively; Fig. 5, H–L). These responses were reversed in HepG2 cells transfected with siRNA STAT3 (Fig. 5, H–L). Taken together, the overexpression of SOCS3 induced the de novo lipogenesis and increased apoB production in HepG2 cells, effects dependent on STAT3.

**SOCS3 Overexpression Did Not Affect the Cholesterol Biosynthesis in HepG2**—A series of experiments was performed to determine the effect of SOCS3 on genes under the control of SREBP-2, such as HMG-CoA reductase and LDLR. HMG-CoA reductase mRNA was induced in HepG2^SOCS3 cells (2.10 ± 0.66-fold; Fig. 6A); conversely, the LDLR mRNA levels were reduced in response to SOCS3 overexpression (∼56% ± 21.6%; Fig. 6B). These changes were not associated with significant variation of HMG-CoA reductase protein level (Fig. 6C). The lack of significant changes of HMG-CoA reductase was also confirmed by the fact that the cholesterol biosynthesis was not altered in HepG2^SOCS3 cells compared with HepG2 cells (Fig. 6D).

**Effect of SOCS3 Overexpression on Insulin-induced PCSK9 Expression**—To corroborate the pathophysiological relevance of our observations, we then investigated the effect of SOCS3 overexpression on insulin signaling. As shown in Fig. 7A, in response to insulin (10^{-7} M), a significant induction of IRS-1 Tyr^{1166} and Akt Ser^{473} phosphorylations was observed in HepG2. Overexpression of SOCS3 (HepG2^SOCS3) cells resulted in a reduced activation of both IRS-1 (Fig. 7A) and AKT (Fig. 7B) in response to insulin. In accordance with previous studies (38), ectopic expression of SOCS-3 appeared to elevate basal
autophosphorylation, although this increase was not statistically significant.

Moreover, STAT3 phosphorylation was induced in response to insulin in control cells (HepG2), whereas SOCS3 overexpression (HepG2SOCS3) determined an abrogation of this response (Fig. 7C). As previously reported by Costet et al. (22), the incubation of HepG2 cells with insulin (10^{-7} M) significantly induced both PCSK9 secretion and mRNA (Fig. 8, A and B), and the presence of SOCS3 further up-regulated the response to insulin at the mRNA levels. However, this effect did not translate to a further induction of PCSK9 secretion in the cultured media, as determined by ELISA assay (Fig. 8A). Similarly, we observed an additive effect of insulin and SOCS3 on the FAS and SREBP-1 mRNA levels (Fig. 8, C and D) with no effect on SREBP-2 and HMG-CoA reductase levels (Fig. 8, E and F).

**Discussion**

In this paper, we tested the hypothesis that the inhibition of the JAK/STAT pathway by SOCS3 could influence the PCSK9 levels in hepatic cell line. The rationale of performing this study is based on at least four previously reported observations. 1) In clinical settings positive relationships of apoB-containing lipoproteins and PCSK9 have been observed (24–27). 2) SOCS3 overexpression in mice induces SREBP-1 transcriptional activation and de novo lipogenesis (6, 7). 3) PCSK9 has been shown to be transcriptionally regulated by SREBP-1 and SREBP-2 (22, 23). 4) The adipokine resistin and insulin induce SOCS3 and PCSK9 expression in cultured cell lines and animal models (5, 39–41).

The first novel aspect that we observed was the induction of PCSK9 in response to the proinflammatory cytokine TNF-α, the same factor that efficiently induces SOCS3 and has been implicated in chronic-inflammation associated with IR (42, 43). To study the possible link between SOCS3 and PCSK9, we first suppressed the expression of SOCS3 by siRNA in HepG2. By using this approach we demonstrated that SOCS3 is required for the TNF-α-driven induction of PCSK9. In addition, the silencing of STAT3 blocked the induction of SOCS3, PCSK9, apoB, and SCD-1 in response to TNF-α (Figs. 1 and 5). Although the effect of proinflammatory cytokines on genes reg-
ulating the de novo lipogenesis has been previously described (42, 44), our data proposes PCSK9 as a gene involved in lipid metabolism regulated by proinflammatory cytokine TNF-α in a SOCS3-dependent manner. We then established a hepatic cell line stably overexpressing SOCS3, the endogenous inhibitor of STAT proteins, and consistently found to be up-regulated in the liver of genetically and diet-induced obese animal (6, 7). By WB analysis, we demonstrated that SOCS3 overexpression abrogated STAT3 phosphorylation and, thus, the JAK/STAT pathway. By using this cellular model, we observed a significant induction of both PCSK9 mRNA and protein. The involvement of both JAK and STAT proteins was then confirmed by the use of selective pharmacological inhibitors, JAK-I and MD77 (36). The suppression of STAT3 by siRNA induced PCSK9, whereas the opposite effect was seen after the down-regulation of SOCS3. In combination with the induction of PCSK9, we also observed increased SREBP-1 processing and a significant up-regulation of the key genes involved in the de novo lipogenesis, such as FAS and the SCD-1 together with the apoB mRNA, apoB, secretion, and intracellular TG. Interestingly, we noticed that PCSK9 was up-regulated in the liver of ob/ob mice together with SOCS3, possibly supporting the link between these two genes as observed in cultured system. However, as STAT3 is regulated by a large number of cytokines, like IL-6 and TNF-α (45), further in vivo studies are needed to elucidate the possible role of STAT3 in SOCS3-driven regulation of PCSK9. The consistent and very significant induction of apoB secretion confirmed the pivotal role of SOCS3 and the related inflammatory pathway on hypertriglyceridemia. In addition, our observation suggested a possible involvement of PCSK9 on apoB production by hepatic cells and/or by the liver of animal models previously described (46–48). For instance,
the physical interaction between PCSK9 and apoB has been shown to increase apoB production, possibly through the inhibition of intracellular apoB degradation (48). Our evidence further delineates the potential link between PCSK9 and apoB by demonstrating that the inhibition of the JAK/STAT pathway by SOCS3 is a common determinant of their increased production and secretion. Notably, recent findings suggest that PCSK9 may directly induce apoB mRNA levels in enterocytes (49). It is, therefore, possible to speculate that SOCS3 could activate a positive feedback loop by increasing the expression levels of PCSK9, which in turn determines the induction of apoB secretion.

Previous studies have established the SREBP-dependent transcriptional activation of PCSK9. Indeed, similarly to the LDLR and other cholesterol-regulated genes, the proximal region of the PCSK9 promoter contains an SRE-1 motif (22, 50). In addition, two independent studies have demonstrated that insulin, by inducing SREBP-1c activity, induces PCSK9 both in vitro and in vivo (22, 41). We confirmed this evidence at both mRNA and protein levels, and the combination of SOCS3 and insulin determined a further induction of de novo lipogenesis genes, SREBP-1, and PCSK9, with no additive effect on PCSK9 secretion. These results are in agreement with previous studies showing that the inhibition of STAT proteins by SOCS3 suppresses the transcription of SREBP-1 (7). In our study the transcriptional activation of SREBP-1 was demonstrated by the induction of key genes involved in the lipid synthesis, such as FAS and SCD-1, whereas SREBP-2 appears to be unaffected by SOCS3 for at least three reasons. The cholesterol biosynthesis was not altered; an opposite regulation of two genes mainly regulated by SREBP-2 was observed (HMG-CoA reductase and LDLR), and the processing from the precursor to the active form of SREBP-2 was not induced in response to SOCS3 overexpression. The involvement of SREBPs was then demonstrated by the fact that the incubation with 25-OH cholesterol, which completely inhibits their activity, abolished PCSK9 expression. The contribution of SREBP-1, over the SREBP-2, in the regulation of PCSK9 was further corroborated by using fatostatin, a selective SREBP-1 inhibitor (35), which completely suppressed the PCSK9 mRNA levels in HepG2SOCS3. The involvement of SREBP-1 on PCSK9 transcriptional regulation has been previously demonstrated (33, 51). In the present study we cannot exclude the involvement of HNF-1α in SOCS3-mediated PCSK9 induction as both protein and mRNA were increased. Moreover, the luciferase assay with the PCSK9 promoter region having either the HNF-1 or SRE site mutated was drastically suppressed. These data suggest a mutual requirement of both SREBP and HNF-1α on transcriptional regulation of PCSK9 (33).

The effect of SOCS3 on PCSK9 transcription, analyzed in HepG2 and HepG2SOCS3, transiently expressing the PCSK9 promoter-driven luciferase reporters PCSK9-D4 (33), found, unexpectedly, that this functional promoter was unresponsive to SOCS3 overexpression (Fig. 2L). These results suggest that the SOCS3 response sequences could possibly locate upstream of the promoter region considered. In this regard it is important to mention that the link between JAK/STAT pathway and PCSK9 has been previously investigated in the same cell line by the use of the cytokine oncostatin M (52). Similar to our study, oncostatin M did not affect the PCSK9 promoter activity (52). Because previous studies have shown that PCSK9 transcription is controlled through cis regulatory elements located in the proximal promoter region of the PCSK9 gene where the Sp1 sites and HNF1 and SRE-1 are located (23, 33, 51) we utilized also a PCSK9-D4 containing a mutation for the HNF-responsive element. Under this condition we detected a significant increase of the promoter activity in HepG2SOCS3 cells. These observation potentially related to the SREBP pathway, activated in response to STAT inhibition, although the overall activity was very low and potentially not responsible for the induction of PCSK9 mRNA levels (7). This effect was also not confirmed with the incubation of the JAK inhibitor, most likely because of the minor inhibition of the pathway in comparison with the complete block after SOCS3 overexpression.

We also exclude a SOCS3 effect on mRNA stability in the induction of PCSK9, as incubation with the transcriptional inhibitor actinomycin D did not affect mRNA stability compared with HepG2. Hence, additional analysis is required to better define the effect of SOCS3 on the transcriptional regulation of PCSK9. Several studies have described the effect of SOCS proteins on insulin signaling (1, 43, 53). Although the observations may differ by the cell type and by the time considered, the majority of the studies suggests that SOCS proteins control insulin action by reducing the expression of IRS proteins (1, 43, 53). Indeed, in our experimental conditions SOCS3
overexpression reduced both IRS-1 and Akt phosphorylation in response to insulin. Moreover, insulin stimulation of HepG2SOCS3 determined a further induction of genes related to de novo lipogenesis (FAS and SREBP-1) as well as PCSK9. Although this finding has been obtained in vitro, it is conceivable to hypothesize a functional contribution of PCSK9 on the hypertriglyceridemic condition observed in type 2 diabetes mellitus and obesity. Indeed, PCSK9 directly affects the VLDR expression at the adipose tissue determining the accumulation of visceral adipose tissue in mice (54). For such an effect PCSK9-deficient mice show adipocyte hypertrophy, enhanced in vivo fatty acid uptake, and ex vivo triglyceride synthesis (54).

In conclusion, in the present study we provide evidence for the JAK/STAT-dependent expression of PCSK9 in the hepatic cell line, suggesting the potential molecular basis of the direct relationship between PCSK9 and TG levels observed in clinical trials (24–27).
STAT3-dependent Regulation of PCSK9

Author Contributions—M. R. and N. F. conceived and coordinated the study, wrote the paper, and designed, performed, and analyzed all the experiments. C. R. performed the experiments shown in Figs. 1, 2, 3, 4, 5, and 7. C. M. performed the experiments shown in Figs. 1, 2, 3, and 6. R. C. performed the experiments shown in Figs. 2 and 3. A. C. and P. M. made critical revisions in the manuscript. J. L. made critical revisions in the manuscript and provided reagents for PCSK9 promoter activity. All authors reviewed the results and approved the final version of the manuscript.
