Abstract

Background Disability is not just a factor of an individual's physical condition; it develops through human interactions and reflects the social fabric of communities. Despite the fact that it directly affects 15% of Ethiopians, understanding and policy-relevant studies on disability and the conditions of persons with disabilities are lacking. The Dabat Demographic and Health Surveillance System part of the response to fill this gap. With significant drawbacks in the Surveillance System, this study aimed at assessing the prevalence, types and major causes of disability in Dabat district.

Method A community-based cross-sectional study design was employed and covered 17,000 households residing in 13 Kebeles of Dabat district. The district is where DHSS collects health data semi-annually; but this study was designed and executed separately in 2018 utilizing robust tools (World Health Organization's Disability Assessment Schedule (WHODAS 2.0) used to collect comprehensive data on disability in the district. The data was organized and presented using frequencies and percentages in table and figures. Relevant variables were used to construct a logit model that predicts the likelihood of disability whereby P-value < 0.05 was considered as statistically significant.

Results This study found that the overall prevalence of disability in Dabat district was 2.14% [95% CI: 2.03, 2.24]. About 8.3% of households reported at least one member with disability. Visual impairment was the most commonly reported impairment (51%) while 8.19% had multiple impairments. Eighty-three percent of immediate the causes of disability were modifiable – specifically, illness (36.93%), injury (17.81%), and congenital (10.86%). The aged [AOR=1.0; 95% CI: 1.03, 1.04], those unable to read or write illiterate [AOR=1.57; 1.15,2.14], the unmarried/single [AOR=1.39; 95% CI: 185,2.47] and the separated [AOR=2.78; 95% CI: 4.14,6.19] were more likely to risk disability in the population.

Conclusion This study reported an increased likelihood of impairment among those with advanced ages. The proportion of households with PwDs was also high. While most disabilities were visual, there were significant numbers with mobility impairments and hard of hearing. Most school-age PwDs did not complete secondary education, while employment was significantly limited. The findings indicated that most causes of disability were reversible.

Background

Disability is part of a human condition that can be experienced by any person at some point in life, temporarily or permanently[1]. As a concept, it has been used to alternatively refer to physical impairments, activity limitations, or participation restrictions. Currently, the WHO-ICF definition of disability is widely adopted i.e. a person is considered to have a disability if and when his/her activity performances in his/her usual environment are limited in nature, function, or quality [2, 3]. Hence, it includes physical or learning and intellectual disability that cause functional limitations, which are consistently related to human dignity and inclusion in society.

The World Health Organization (WHO) and the World Bank (WB) estimated that about 80% of the global 1 billion persons with disabilities (PwDs) currently live in developing countries where rehabilitation services
are poor or non-existent[1]. These numbers are increasing – both globally and in developing countries – due to population growth, man-made and natural disasters, war, accidents and ageing.

On the other hand, data on the proportion of PwDs in Ethiopia is highly fragmented or sometimes misleading and contradictory. For example, based on the 2007 Population and Housing Census, Ethiopian Central Statistical Authority (2007) reported that there were less than 1 million Ethiopians with disability i.e. 1.2% [4]. Conversely, WHO’s World Disability Report (2011) indicates that the national prevalence of disability in Ethiopia is around 17% [1]. The incongruence between the two sources of disability statistics could be explained by the multidimensionality of disability that makes its measurement variable. The World Disability Report explains, “Operational measures of disability vary according to the purpose and application of the data, the conception of disability, the aspects of disability examined, the definitions, question design, reporting sources, data collection methods, and expectations of functioning” (1). In Ethiopia, many are skeptical about the census statistics on disability that could have been affected by “under-reporting, the way the census questions were formulated, lack of disability awareness among enumerators and data managers and use of a narrow definition of disability” in the census [5]. Others have argued the census figure actually reveals the number of PwDs in Ethiopia has not been identified yet[6].

Despite their inconsistencies and contradictions, literature and statistical reports on disability in Ethiopia identify mobility, visual and hearing impairments as the top-three most prevalent forms of disabilities, in that order [7]. The prevalence and types have also been reported to be similar in North Gondar Administrative Zone of the Amhara National Regional State (ANRS), Ethiopia [8, 9].

Reliable statistics on disability is a requirement to promote inclusive and sustainable development. It will furnish data on the level of functioning in the population, the need for rehabilitation services and equalization of opportunity by helping identify the barriers to PwDs’ inclusion and participation in community affairs. PwDs have the rights to equal opportunities to schooling and employment as well as access to health and other services. In recent years, national and global actors have pushed the issue of disability to the center and front of policies, programing and service provision to ensure the effective inclusion of PwDs in development [10-12].

The causes and impacts of disability on people are numerous and complex. In Africa, nonetheless, it is evident that the major causes of disability are communicable diseases, war, accidents, and inadequate prenatal and neonatal healthcare services. Studies have also shown that disability is strongly linked to underlying and basic problems of poverty, poor nutrition and restricted access to basic services such as health and schooling [9]. These factors are also relevant to the Ethiopian context where the list of causes/factors include low standard of living, malnutrition, natural and man-made disasters, accidents, infectious and non-infectious diseases, intermittent wars and violence [8, 13].

Negative attitudes and limited understanding around disability and people with disabilities can contribute to poor mental health and well-being, and, lead to societal exclusion across many life domains [14]. But persons with disabilities do not form a homogenous group. Alongside a variety of different types of impairments (e.g. physical, psycho-social, sensory, intellectual, neurological), people with disabilities live in a variety of contexts with different intersecting identities. This may include gender, age, education status,
employment and economic status, and, geographical location. How these contexts and different characteristics intersect, lead to very different experiences of disability[15]. In Ethiopia, for instance, about 46% of PwDs are women [16] and they carry the double burden of stereotypes, discrimination and economic challenges associated with their gender and disability. Age is also a factor whereby children with disabilities (CwDs) are less likely to attend schooling or access healthcare services leaving them vulnerable to poverty and poor health that substantially reduce their quality of life [17, 18]. As a group, without underplaying these variations within, PwDs are still among the most disadvantaged segment of the society.

With existing and emerging man-made and natural disasters, technological changes and global communications, disability statistics and surveillance are necessary to assess and examine trends on the conditions of PwDs to inform policies and strategies on inclusive and sustainable development as well as programming for delivery of social- and healthcare- services. Specifically, disability statistics and surveillance furnish empirical and reliable data on needs, priorities, strategies and resources that promote the effectiveness of interventions to meet the challenges of PwDs. By doing so, they will contribute to filling the existing knowledge gap on disability – its magnitude, types, effects, trends, etc. – in Ethiopia at policy, research and programming levels.

Researches have documented the complicated relationship among disability, its social and health outcomes and national and contextual realities; and, the provision of long-term everyday care for PwDs is becoming a major problem on public health policy and programming especially in developing countries where resources, qualified personnel and rehabilitation centers and services are very limited. It is against this backdrop that University of Gondar (UoG) launched the Dabat Health Surveillance System (DHSS) in 1995 to collect, organized and disseminate regular and up-to-date information on the health conditions of the population (including PwDs) in Dabat district, northwestern Ethiopia. Nonetheless, with the focus of Dabat Research Center being on general health and demography, it only started to collect data on disability recently and even that didn’t employ robust, internationally-validated disability measurement tools to assess the status of disability in the district. As a result, the Center reports significantly low disability prevalence in the district. This study, hence, aimed at assess the prevalence, types and causes of disability on residents of the Dabat district employing a disability measurement tool containing items from WHO Disability Assessment Schedule (WHODAS 2.0) and the International Classification of Functioning, Health and Disability (ICF).

**Methods**

**Study Area**

This paper discusses disability and conditions of PwDs in Dabat district, northwestern Ethiopia – the district covered by DHSS longitudinal study. Dabat town is located 60kms northwest of Gondar city, and it serves as an administrative center of the Dabat district. The district has an estimated population of 168,331 (male/female: 50%) (CSA 2013) that occupy 1,199.15km$^2$ area. It is administratively organized under 5 urban and 27 rural Kebeles with altitudes ranging between 1000 and 3000 meters above sea level (Dabat Rural Project Statistics, 2015).
The district has 29 health posts, 3 health stations and 2 health centers. UoG established DHSS in 1995 to collect demographic, social and health data in 13 *Kebeles* (9 rural and 4 urban) of 32 *Kebeles* of the district. According to the 2014 Re-census Baseline Survey, DHSS collects data on 17,000 households, with 72,000 inhabitants, semi-annually.

**Study Design**

To identify the prevalence, causes and associated factors of disability at Dabat district, the study used a community-based cross-sectional design. The fieldwork was conducted between January and June 2016 to 2020.

**Study Population**

This study covers all members and permanent residents of the 17,000 households covered by the DHSS in Dabat district. Data on disability was gathered from household heads residing in 13 *Kebeles* of the district. The DHSS staff and enumerators collect health and demographic data on well-defined entities or primary subjects (individuals, households, and residential units) semi-annually (and changes over time) by visiting the 17,000 households and their members.

This study reports and discusses the findings of a separate cross-sectional study on the same study population, but exclusively focusing on disability and employing robust disability measurement tools to collect household data and assess the prevalence, causes and associated factors of disability vis-à-vis socio-demographic and other relevant dimensions.

**Sample size and sampling procedures**

Theoretically, this study included all 17,000 households and their members and permanent residents as well as those on the streets in the 13 *Kebeles* within the Dabat DHSS catchment area. It excluded those who were not-permanent residents (less than 6 months, as per the CSA definition of ‘household members’) at the time of data collection.

**Data collection: tools and procedure**

The community survey employed a structured and pre-tested questionnaire containing items adapted from The World Health Organization Disability Assessment Schedule (WHODAS-2.0) and the International Classification of Functioning, Health and Disability (ICF) to reflect local contexts. Respondents were asked to provide information on household members with signs of disability including hard of hearing or total loss, visual impairment or blind, speech impairment, loss of senses or limbs, paralysis, diagnoses insanity, etc. The information gathered on disability through the community survey did not account for mild or moderate type of disability. It was then translated and deployed in its Amharic – language of the local community. With the questionnaire being not validated in Ethiopian context, the researchers relied on their robust researching and programing experiences on disability, inclusion and community rehabilitation in the Dabat district to contextualize and ensure its culture-appropriateness and scientific validity. Furthermore, it was pre-tested on a population with similar demographic and socioeconomic profile as the study area, with
its outcomes used to review and adapt its framework, organization as well as items sequencing and wording.

WHODAS-2.0 is a standardized and validated tool to assess health and disability status both at individual and community levels, and across cultures [19]. As a generic tool, it effectively assesss disability induced limitations on activity and participation both in community and clinical set-up. Furthermore, it has been fruitfully deployed to measure the effectiveness of disability interventions [19]. The survey questionnaire specifically adapted items from WHODAS-2.0 that measure the six domains of disability: learning and intellectual, mobility, self-care, getting along, life activities and participation.

The questionnaire had also included items from International Classification of Functioning, Health and Disability, Children & Youth version (ICF-CY) to assess disability, activity limitations and other outcomes among population under 18 years of age. Survey data were collected by well-trained data collectors and DHSS staffs who administered the questionnaire through face-to-face interview. They visited all 17,000 households in Dabat district and interviewed heads of households to collect the necessary information on all members of the household, including themselves. The use of self-reporting rather than conducting clinical screening on household members to collect data on disability is identified as the limitation of this study. Finally, when new cases of disability were identified or reported, they were referred and/or linked to local Community-based Rehabilitation (CBR) fieldworker.

**Data analysis**

Data were entered into the Household Registration System (v- 2.1) and the survey data was entered into and analyzed using STATA (v.12) software. Descriptive statistics – means, percentages, standard deviation, etc. – were employed to describe the characteristics of the study population. Table and figures were used to present aggregated and disaggregated, as appropriate, data. Binary logistic regression was fitted to test and identify factors significantly associated with disability. The bivariate analysis was carried out, and variables with p-values of <0.2 were entered into the multivariable logistic regression model. The crude odds ratio (COR) and finally, a Logistic regression models were constructed on predictors of disability among the study population. The adjusted odds ratios with the corresponding 95% Confidence Interval (CI) were used to show the strength of association between independent variables (age, sex, place of residence, religious affiliation, educational attainment, occupation marital status) and disability. A p value of <0.05 was considered statistically significant.

**Results**

**Respondents’ socio-demographic characteristics:** As Table 1 shows, survey data was collected on 71,916 members of 17,000 households in Dabat district. Among this, 36,462 (50.7%) were females, and 54,489 (75.77%) lived in rural areas. The Table also reports that 22,274 (30.97%) cannot read and write, while 22,133 (30.78 %) and 26,394 (36.7%) were aged, respectively, under 14years and 18 years. Based on sex, 71.8% of female and 52.9% of male PwDs cannot read or write; and, females made up two-thirds of PwDs who cannot read or write.
Prevalence and types of disability: The overall prevalence of disability in Dabat district was 2.14% [95% CI: 2.03, 2.24]. Higher prevalence was noted among females (2.29%) than males (1.97%). As Table 2 and Figure 1 reveal, the prevalence of disability increased with increase in age, and reached the highest level among persons of 65 and above years old (10.18%). Conversely, the prevalence of disability declined with increase in educational status. For instance, the highest proportion of disability – 971 (63.2%) – was recorded among those who cannot read and write, and the difference is stark when we compare it to those with Grade 11/12 (0.72%) and Grade 12+ (0.98%) education (Table 3).

More than 8% of households had a member with disability (1411 in 17,000 households). Table 1 also reports that the prevalence of disability was high among those with 'separated' (63 (10.21%)) and widowed (176 (9.33%)) marital statuses as well as the unemployed (5.42%). There was marginal variation between urban (2.08%) and rural (2.15%) Kebeles of Dabat district in terms of the number of people affected by disability (Table 1).

Eight percent of the PwDs had more than one type of disability. In terms of single-disabilities, 51% had visual impairment, while 24.3% had mobility impairment and 22.3% were hard of hearing. Noticeably, there was a marked increase in hearing and visual impairments among ageing respondents (Table 2 & Figure 2).

On the other hand, only 253 (16.5%) PwDs attended any form of formal education. In fact, as educational level increases, the proportion of PwDs who attended higher grade-levels fell significantly with less than 1% completing secondary education (Table 3).

With regard to occupation, small proportions of PwDs were government employees in urban (2.03%) and rural (0.35%) areas. More men (urban, 20.2%; rural, 52.8%) than women (urban, 14.8%; rural, 47.1%) worked on the farm, and farming was the main occupation for residents in urban (17%) and rural (49.8%) areas (Table 4). Conversely, more women (urban, 24.1% vs. 14.6%; rural, 17.8% vs. 7.9%) were household servants, while more men (urban, 12.3% vs. 8.1%; rural, 11.1% vs. 1.3%) were engaged in private works compared to their women counterparts (Table 4).

The survey identified the most frequent causes of disability as illness (36.93%), followed by accidents (17.81%), unknown (11.57%), congenital (10.86%) and ageing (5.2%). In other words, more than 83% of the reported immediate causes of impairments could have been prevented from causing functional limitations if they were identified and treated early (Table 5 and Figure 4).

Factors associated with disability: Multivariate logistic regression model was constructed to predict the occurrence of disability in the study population from data on respondents’ age, educational attainment and marital status. The model found age [AOR= 1.0; 95% CI: 1.03, 1.04], educational attainment [AOR=1.15;95% CI: 1.57, 2.13], and marital status i.e. being single [AOR: 1.39; 95% CI: 185,2.47] and separated [AOR: 2.78; 95% CI: 4.14,6.19] as significant predictors of disability in the study population (Table 6).

Discussion
This study found that though the general prevalence of disability was 2.14%, it significantly affects older people in the community. The proportion of households with members with disability i.e. 8.3% was high when compared to previous studies on the study area. As questionable they were in reliability, representativeness or timeliness, CSA [20] and Chala [21] reported 1.82% and 1.09%, respectively, disability prevalence for Dabat district, which were significantly lower than the 2.14% reported in this study. However, 2.14% is still significantly lower than an estimated 17.6% national disability prevalence rate in Ethiopia that WHO and WB (2011) reported [1, 11].

There are several possible explanations why different sources provide different reports on the prevalence of disability. For one, WB and WHO conceptualize disability broadly and include various factors and types, such as chronic illnesses as well as moderate and minor impairments, within the rubric of ‘disability.’ However, limited resources for rehabilitation services and supporting PwDs in developing countries may have dictated a narrower operationalization of disability. In other words, pragmatic conceptualization of disability would set realistic expectations and recommendations for policy formulation and social work practice. For another, The study relied on the responses household heads provided to estimate the prevalence of disability in the district. By its design, the quality of data could be affected by respondents’ lack of knowledge on the nature and degree of one’s and household members’ disability, and negative attitude towards disability and PwDs, among other. Hence, lack of understanding on disability, stigma attached to disability in the district and respondents’ inability to identify all types and degrees of disability may have lowered reports on disability in the study area.

In terms of type of disability, this study reported similar results as the same teams previous study in Dabat district [21]. Both studies found that visual impairment affects the highest proportion of PwDs; but while the current study found that mobility and hearing impairments are second and third in the number of people they affect, their relative proportion was reversed three years earlier [21].

A small fraction of PwDs attended formal education; and more importantly, with advance in educational level, their progression to higher grades decreases significantly. This result was consistent with the Handicap International report that indicated a small fraction (3%) of the estimated 2.4 to 4.8 million school-age CwDs went to school. CwDs’ low school attendance and participation are due to underlaying reasons that include stigma against CwDs, school inaccessibly, rigid teaching practice, poorly trained teachers to accommodate children with special needs and lack of adaptive hearing resources [22]. Another study in South Africa documented how PwDs and their families live with stigma and social exclusion that affect their personal development and community participation [23]. Other studies [17, 24] also report CwDs are less likely to attend schooling and access health care, and they are more vulnerable to poverty which may result in substantial decline in their quality of life.

This study reported that the majority of disabilities were due to illnesses, injuries, etc.; and the causes and impacts of disability are multifaceted. Concurrent to these findings, studies have documented that the majority of disabilities in Africa result from illness, injury, and accidents – causes that are preventable [9, 25]. In Ethiopia, diseases like measel, poliomyelitis, etc. as well as accidents and injuries cause illnesses to many people that – if identified and treated early or on time – may not necessarily amount to serious
functional and activity limitations. Most disabilities and their causes can be linked to poverty, and restricted access to basic services [26-28]. As this study reported, most PwDs were poor – both in urban and rural areas – and a significant majority of them were involved in small-scale farming with strained livelihoods. Besides, inadequate health care services were also significant contributors to the disability problem on the continent [19], which is the same in the Dabat district.

Disability causes serious bad health outcomes, and the provision of long-term care for PwDs in resource limited settings is a major public health problem. Disability is especially a concern for developing countries where prevention approach and health service services are inadequate or very scarce [18]. Moreover, stigma and stereotypes limit educational and employment opportunities for PwDs thereby creating dependency and exclusion for PwDs [29] – and this study underlines these facts.

In Ethiopia when it comes to women with disabilities, they carry the double burden of stigma and discrimination and economic problem due to their gender-roles and disability [16]. Disability and poverty exacerbate their socioeconomic wellbeing and their general quality of life.

**Strengths and Limitations**

The study aimed at exploring factors and the prevalence of disability and its deleterious impacts in low resource setting i.e. Dabat district, Northwestern Ethiopia. Large size samples were drawn to collect representative empirical data about the population. Literature review revealed that there is dearth of scientific, empirical information to understand the trend and changes on the prevalence and magnitude of disability and its effects in Ethiopia. It has also established the evident fact that there is low community and governmental attention on disability and the empowerment of PwDs in developing countries such as Ethiopia. Therefore, by identifying contributing factors to disability and its prevalence and impacts on peoples’ lives in northwest Ethiopia, this study will promote disability awareness and inclusive society as well as inform the agenda for disability research, policy and practice in the district and beyond.

**Conclusion**

This study found the proportion of reported disability per household to be high. Vision and mobility disability were the most frequently observed types of disability, and most immediate causes of disability were modifiable. This conclusion, however, does not apply to underlying structural factors to disability such as poverty, aging, inaccessibility of health services, etc. that require programmatic interventions at national, regional and local levels. On the other hand, this study indicated that the prevalence of disability increased among the ageing-groups. As educational level increase, the proportion of PwDs attending school decreases, and most PwDs do not complete secondary education. Similarly, a small proportion of PwDs were government employees, and the majority were engaged in farming.

Early intervention and appropriate medication will prevent the burden of disability. To this end, appropriate attention should be given to improve quality of healthcare facilities and services to reduce the burden of disability on families, communities and the health care system. Moreover, community awareness creation and enhancing inclusive education will improve education opportunity for PwDs. With improve in
educational level and skills, PwDs will be able to find and/or create jobs thereby promoting their independence and better quality of life. Further qualitative research is recommended to examine contextual factors that influence the social participation and quality of life of PwDs in the context of Dabat district.

**Declarations**

**Ethical considerations**

The University of Gondar's Institutional Review Board (UoG-IRB) cleared the research for meeting required and appropriate ethical standards. Two support letters - from the Vice President's Office for Research and Community Services and the College of Medicine and Health Sciences – were submitted to Dabat District Administrator. Letter of information describing the purpose and objectives of the study, and written informed consent was obtained from the study participant (household head), and consent forms were given or read to study participants prior to the commencement of the interview. Participants were granted the right to terminate their participation in the study at any point if and when they chose to.

Once in the field, researchers and DHSS staff put their maximum efforts in assuring all ethical and scientific standards are maintained. Participants' privacy and confidentiality were respected during and after interviews. Once data was collected, each questionnaire was coded, and personal identifiers were removed to maintain anonymity and confidentiality of participants. All data was entered and saved on a computer
with a strong password which was only accessible by the research team. Participants who reported
disability or were found ill during data collection were either linked to UoG-CBR fieldworkers or health centers
for better care.

**Consent for publication:** "Not applicable"

**Data sharing statement:** Since the data presented in this report are the part of the large DHSS survey data,
we have to abide by the data sharing policy of University of Gondar; nonetheless, we have included all
important information regarding data presented on the tables and figures (No additional data are available).

**Competing interests:** The authors declare no financial and non-financial competing interests

**Funding:** University of Gondar, Ethiopia

**Authors’ contributions**

SMA, MB, MB, SF, AN, MA, Z, WW, AF, designed the study;

SMA, performed the analysis and interpretation of data; and,

SMA, MB, MB, SF, AN, MA, Z, WW, AF, drafted and finalized the write-up of the paper.

All authors prepared the draft manuscript, read and approved the final manuscript.

**Acknowledgement**

We would like to acknowledge the University of Gondar for the financial support. We extend our thanks to
the Dabat District Health Office for their permission to conduct the study. We want to express our gratitude
to all staff of the Dabat DHS and the study participants.

**Authors’ Information**

We confirm that the manuscript has been read and approved by all named authors,
