Schwarz alternating methods for anisotropic problems with prolate spheroid boundaries

Zhenlong Dai, Qikui Du* and Baoqing Liu

Abstract

The Schwarz alternating algorithm, which is based on natural boundary element method, is constructed for solving the exterior anisotropic problem in the three-dimension domain. The anisotropic problem is transformed into harmonic problem by using the coordinate transformation. Correspondingly, the algorithm is also changed. Continually, we analysis the convergence and the error estimate of the algorithm. Meanwhile, we give the contraction factor for the convergence. Finally, some numerical examples are computed to show the efficiency of this algorithm.

Keywords: Schwarz alternating algorithm, Exterior anisotropic problem, Prolate ellipsoidal, Artificial boundary, Iteration method

Background

How to deal with boundary value problems has always been a essential part of partial differential equation. Finite difference method (FDM) (Evans 1977) and finite element method (FEM) (Brenner and Scott 1996) are the most widely used method to solve PDE numerically. These two methods become in vain when it comes to the problem over unbounded domain. To overcome this, boundary element method (BEM), which can reduce the dimension of the computational domain and is suitable for solving problems in the unbounded domains, is proposed in Feng (1980). Although, it is better to handle BEM with infinite regions, it doesn’t work so well as FEM in bounded ones. Hence, the coupling of BEM and FEM becomes the interest of researchers. Papers MacCamy and Marin (1980), Hsiao and Porter (1986), Wendland (1986), Costabel (1987), Han (1990) had focused on this method. In 1983, Feng firstly proposed a direct and natural coupling method. Later in the same year, Feng and Yu (1983) formally named the method as natural boundary element method (NBEM). Meanwhile, the DtN method, which has the similar principle with NBEM, is proposed in Keller and Givoli (1989), Grote and Keller (1995). Du and Yu (2001), Hu and Yu (2001), Gatica et al. (2003), Koyama (2007), Koyama (2009), Das and Mehrmann (2016), Das and Natesan (2014), Das (2015) and references therein present the applications of this methods.
Among the reasons that effects the NBEM, the shape of artificial boundary is the essential one. Classically, circle (Givoli and Keller 1989) and spherical (Grote and Keller 1995; Wu and Yu 1998, 2000a) are chosen as the artificial boundaries. Few papers Grote and Keller (1995), Wu and Yu (2000b), Huang and Yu (2006) focus on the special artificial boundaries. These papers also proved the classic artificial boundaries were not suitable for the problem with irregular shape. On the other hand, the coupling of FEM and BEM are not enough as the performance of computer developed. The domain decomposition method (DDM) (Brenner and Scott 1996), which separates the infinite region as sum of bounded one and unbounded one with an artificial boundary on which an iteration method is constructed in, is applied on the NBEM (Yu 1994). Wu and Yu (2000b) applied this method over an infinite region. Continually, Huang et al. (2009) and Luo et al. (2013) applied this method in different problems.

In this paper, we consider the anisotropic harmonic problem over an exterior three-dimensional domain. A Schwartz alternating method is designed for the numerical solution with prolate artificial boundaries.

The outline of the paper is as follows. In “Schwarz alternating algorithm based on NBR” section, we divide the original domain $\Omega$ into two overlapping subdomains $\Omega_1$ and $\Omega_2$ by choosing two artificial boundaries $\Gamma_1$ and $\Gamma_2$, then we construct the Schwarz alternating algorithm. We prove the convergence of the algorithm in “Convergence of the algorithm” section. The convergence rate of the algorithm is analysed in the “Analysis of the convergence rate” section. In “The error estimates of the algorithm” section, we deduce the error estimates of the discrete algorithm. In “Numerical results” section, numerical examples are computed to express the advantages of this method. Finally, we give some conclusions in “Conclusions” section.

### Schwarz alternating algorithm based on NBR

Let $\Omega \subset R^3$ be a cuboid Lipschitz unbounded domain and $\Gamma_0 = \partial \Omega$ is its boundary. We consider the following exterior Dirichlet problem

\[
\begin{cases}
-\left(K_1 \frac{\partial^2}{\partial x^2} + K_1 \frac{\partial^2}{\partial y^2} + K_2 \frac{\partial^2}{\partial z^2}\right) u = 0, & \text{in } \Omega, \\
u = g, & \text{on } \Gamma_0, \\
u \to 0 & \text{as } r \to \infty,
\end{cases}
\]

where $K_1$ and $K_2$ are two different anisotropic parameters, $g$ is a given function that satisfies $g \in H^{1/2}(\Gamma_0)$, and $r = \sqrt{x^2 + y^2 + z^2}$. The third item of Eq. (1) keeps the existence and uniqueness of the solution.

Let $\Gamma_1 = \{(x, y, z) : \frac{x^2}{b^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1, \ c > d > 0\}$ and $\Gamma_2 = \{(x, y, z) : \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{a^2} = 1, \ a > b > 0\}$ denote two artificial prolate spheroids. For clarity, we must mention that $d > b$ and $c > a$. This means that $\Gamma_2$ is totally inside $\Gamma_1$. Define $\Omega_2$ as the unbounded domain outside the boundary $\Gamma_2$ and $\Omega_1$ be a bounded domain between $\Gamma_0$ and $\Gamma_1$ (see Fig. 1).

According to DDM (Brenner and Scott 1996), we construct the Schwarz alternating method as follows:
and where \( k = 0, 1, \ldots \) and \( u_2^{(0)} = \bar{u} \).

Setting the initial value of function \( u_2^{(0)} \) on boundary \( \Gamma_1 \) as \( u_2^{(0)}|_{\Gamma_1} = 0 \). Hence, we can solve the problem (2). Furthermore, with the limitation of \( u_1^{(1)} \) on \( \Gamma_2 \), one solves the problem (3). Sequentially, we solve the problem in \( \Omega_1 \) again with substituting the value of solution \( u_2^{(2)} \) on \( \Gamma_1 \). Then, we repeat the steps for \( k = 1, 2, \ldots \) and so on.

By the above description, obviously, we applied FEM in the problem over \( \Omega_1 \) and BEM (Feng and Yu 1983) in \( \Omega_2 \). Before using BEM to solve problem (3), the following transformation is introduced.

\[
\begin{align*}
x &= \sqrt{K_1} x_1, \\
y &= \sqrt{K_1} y_1, \\
z &= \sqrt{K_2} z_1.
\end{align*}
\]

For simplicity, the corresponding signals under the coordinate system \((x_1, y_1, z_1)\) can be defined by adding an apostrophe on the original ones, e.g. \( \Omega \rightarrow \Omega' \). Therefore, problem (3) can be expressed as the harmonic problem according to the new coordinate system.

\[
\begin{align*}
\begin{cases}
- \left( K_1 \frac{\partial^2}{\partial x^2} + K_1 \frac{\partial^2}{\partial y^2} + K_2 \frac{\partial^2}{\partial z^2} \right) u_1^{(2k+1)} = 0, \quad \text{in } \Omega_1, \\
u_1^{(2k+1)} = u_2^{(2k)}, \quad \text{on } \Gamma_1, \\
u_1^{(2k+1)} = g, \quad \text{on } \Gamma_0, \\
\end{cases}
\end{align*}
\]

and

\[
\begin{align*}
\begin{cases}
- \left( K_1 \frac{\partial^2}{\partial x^2} + K_1 \frac{\partial^2}{\partial y^2} + K_2 \frac{\partial^2}{\partial z^2} \right) u_2^{(2k+2)} = 0, \quad \text{in } \Omega_2, \\
u_2^{(2k+2)} = u_2^{(2k+1)}, \quad \text{on } \Gamma_2, \\
u_2^{(2k+2)} \rightarrow 0, \quad \text{as } r \rightarrow \infty,
\end{cases}
\end{align*}
\]
We introduce the prolate spheroidal coordinates \((\mu, \theta, \phi)\), such that \(\hat{W}_1^{(2k+2)}\) coincides with the prolate spheroid \(\mu = \mu_2\) and \(\Omega_2 = \{(\mu, \theta, \phi) | \mu > \mu_2 > 0, \theta \in [0, \pi], \phi \in [0, 2\pi]\}).

\[
\begin{align*}
  x_1 &= f \sinh \mu \sin \theta \cos \phi, \quad \mu \geq \mu_2 > 0, \\
  y_1 &= f \sinh \mu \sin \theta \sin \phi, \quad \theta \in [0, \pi], \\
  z_1 &= f \cosh \mu \cos \theta, \quad \phi \in [0, 2\pi],
\end{align*}
\]

where \(f = \sqrt{\frac{a^2}{K_1} - \frac{b^2}{K_2}}, a = f \cosh \mu_2\) and \(b = f \sinh \mu_2\).

For simplicity, the problem (5) can be expressed as

\[
\begin{align*}
  &-\Delta u = 0, \quad \text{in } \Omega_2', \\
  &u = u_1, \quad \text{on } \Gamma_2', \\
  &u \to 0, \quad \text{as } r' \to \infty.
\end{align*}
\]

By the separation of variable (Zhang and Jin 1996), we have the solution of (7) as follows

\[
u(\mu, \theta, \phi) = \sum_{n=0}^{\infty} \sum_{m=-n}^{n} \frac{Q_n^m(\cosh \mu_2)}{Q_n^m(\cosh \mu_1)} U_{nm} Y_{nm}(\theta, \phi)
\equiv H(u_2, \mu, \theta, \phi), \quad \mu \geq \mu_2 > 0,
\]

where

\[
U_{nm} = \int_0^{2\pi} \int_0^\pi u_2(\mu_2, \theta, \phi) Y_{nm}^*(\theta, \phi) \sin(\theta) d\theta d\phi,
\]

\[
Y_{nm}^* = (-1)^m Y_{nm}(\theta, \phi) = (-1)^m \sqrt{\frac{2n + 1 (n - m)!}{4\pi (n + m)!}} P_n^m(\cos(\theta)) e^{im\phi}.
\]

\(P_n^m\) and \(Q_n^m\) are the first and second kind of the associated Legendre functions. Therefore, the solution \(u\) of (7) restricted on \(\Gamma_1'\) can be expressed as

\[
u(\mu_1, \theta, \phi) = H(u_2, \mu_1, \theta, \phi).
\]

Similarly, we have the equivalent problem of (2). Thus, the Schwarz alternating algorithm can be expressed as follows:

\[
\begin{align*}
  &-\Delta u_1^{(2k+1)} = 0, \quad \text{in } \Omega_1', \\
  &u_1^{(2k+1)} = g', \quad \text{on } \Gamma_0', \\
  &u_1^{(2k+1)} = u_2^{(2k)}, \quad \text{on } \Gamma_1',
\end{align*}
\]
and
\[
\begin{align*}
-\Delta u_2^{(2k+2)} &= 0, & \text{in } \Omega_2', \\
u_2^{(2k+2)} &= u_1^{(2k+1)}, & \text{on } \Gamma_2', \\
u_2^{(2k+2)} &\to 0, & \text{as } r' \to \infty.
\end{align*}
\]
(10)

where \( k = 0, 1, \ldots \). The detail is similar to the original.

**Convergence of the algorithm**

We define the following spaces
\[
W_0^1(\Omega') = \left\{ v \in L^2(\Omega') : \frac{\nu}{\sqrt{1+x_1^2+y_1^2+z_1^2}} \in L^2(\Omega') \right\},
\]
\[
\bar{W}_0^1(\Omega') = \{ v \in W_0^1(\Omega') | \nu|_{\Gamma_0} = 0 \}.
\]

Solutions of (9) and (10) are in \( V_1 = H_0^1(\Omega_1') \) and \( V_2 = \bar{W}_0^1(\Omega_2') \), respectively. Moreover, we denote the \( \bar{W}_0^1(\Omega') \) as \( V \). Both functions of \( V_1 \) and \( V_2 \) can be extended into \( V \). For example, we can extend \( u \in V_1 \) by zero in \( \Omega \setminus \Omega_1' \) to a function in \( V \).

Hence, we have the equivalent variational form of (5):
\[
\begin{align*}
\begin{cases}
\text{Find } w = u - \tilde{u} \in \bar{W}_0^1(\Omega'), & \text{such that} \\
D_{\Omega'}(w, v) = -D_{\Omega'}(\tilde{u}, v), & \forall v \in \bar{W}_0^1(\Omega'),
\end{cases}
\end{align*}
\]
(11)

where \( D_{\Omega'}(u, v) = \int_{\Omega'} \nabla u \cdot \nabla v \, dx \, dy \, dz \), \( \tilde{u} \in W_0^1(\Omega') \) has compact support and \( \tilde{u}|_{\Gamma_0} = g, |u|_1 = \sqrt{D_{\Omega'}(u, u)} \) is an equivalent norm of \( \bar{W}_0^1(\Omega') \). If \( g \in H^\gamma(\Gamma_0') \), then there exists \( \tilde{u} \) such that the solution of (11) exists and is uniquely determined.

Then (9) and (10) are equivalent to the following variational problems:
\[
\begin{align*}
\begin{cases}
\text{Find } w_1^{(2k+1)} = u_1^{(2k+1)} - u_1^{(2k)}|_{\Omega_1'}, & \text{in } \Omega_1', \\
D_{\Omega_1'}(w_1^{(2k+1)}, v) = -D_{\Omega_1'}(u_1^{(2k)}, v), & \forall v \in V_1,
\end{cases}
\end{align*}
\]
(12)

and
\[
\begin{align*}
\begin{cases}
\text{Find } w_2^{(2k+2)} = u_2^{(2k+2)} - u_2^{(2k+1)}|_{\Omega_2'}, & \text{in } \Omega_2', \\
D_{\Omega_2'}(w_2^{(2k+2)}, v) = -D_{\Omega_2'}(u_2^{(2k+1)}, v), & \forall v \in V_2.
\end{cases}
\end{align*}
\]
(13)

Let
\[
\begin{align*}
u^{(2k+1)} &= \begin{cases} u_1^{(2k+1)}, & \text{in } \Omega_1' \\ u_2^{(2k)}, & \text{in } \Omega_1', \Omega_1'' \end{cases}, \\
u^{(2k+2)} &= \begin{cases} u_1^{(2k+1)}, & \text{in } \Omega_1', \Omega_1'' \\ u_2^{(2k+2)}, & \text{in } \Omega_2' \end{cases} \\
u^{(2k+3)} &= \begin{cases} u_1^{(2k+2)}, & \text{in } \Omega_1', \Omega_1'' \\ u_2^{(2k+3)}, & \text{in } \Omega_2' \end{cases}.
\end{align*}
\]
and \( u^{(0)} = \tilde{u} \), then we have
\[
D_{\Omega'}(u - u^{(2k+1)}, v_1) = 0, \quad \forall v_1 \in V_1, \\
D_{\Omega'}(u - u^{(2k+2)}, v_2) = 0, \quad \forall v_2 \in V_2.
\]

Noticing
\[
u^{(2k+1)} - u^{(2k)} \in V_1, \quad u^{(2k+2)} - u^{(2k+1)} \in V_2
\]
and
\[
u - u^{(2k+1)} \in V, \quad u - u^{(2k+2)} \in V,
\]
Hence,
\[
u^{(2k+1)} - u^{(2k)} = PV_1(u - u^{(2k)}), \quad u^{(2k+2)} - u^{(2k+1)} = PV_2(u - u^{(2k+1)})
\] (14)

where \( PV_i : V \to V_i (i = 1, 2) \) means the projection operator under the inner product \( D_{\Omega'}(\cdot, \cdot) \) in \( V \). Thus (14) is equivalent to
\[
\begin{cases}
u - u^{(2k+1)} = PV_1(u - u^{(2k)}), \\
u - u^{(2k+2)} = PV_2(u - u^{(2k+1)}).
\end{cases}
\] (15)

Denote the errors as \( e^{(k)}_i = \nu - u^{(k)} (i = 1, 2) \). This leads to
\[
\begin{cases}
u^{(2k+1)} = PV_1PV_2e^{(2k-1)}_1, \\
u^{(2k+2)} = PV_2PV_1e^{(2k)}_2,
\end{cases}
\]

This implies that, if \( \{e^{(2k+1)}_1\} \) and \( \{e^{(2k)}_2\} \) are convergent, then their limits are in \( V_1^\perp \cap V_2^\perp \). Similar to the proofs given in Yu (1994, 2002); Luo et al. (2013) we can show the following result.

**Theorem 1** *There exists a constant \( \alpha, 0 \leq \alpha < 1 \), such that*
\[
\|[e^{(2k+1)}_1]\|_1 \leq \alpha^{2k}\|[e^{(1)}_1]\|_1, \quad \|[e^{(2k+2)}_2]\|_1 \leq \alpha^{2k+2}\|[e^{(0)}_2]\|_1.
\]

It is obvious to conclude \( \alpha \) keeps the convergence of Schwarz alternating method. In the next section, we will prove the contraction factor \( \alpha \).

**Analysis of the convergence rate**

By Theorem 1, one may find the convergence rate of the above Schwarz alternating algorithm is closely related to the contraction factor \( \alpha \), i.e. the overlapping extent of \( \Omega'_1 \) and \( \Omega'_2 \). Although it can be deduced intuitively that the larger the overlapping part is, the faster convergence rate will be, yet we find it difficult to analyse the convergence rate for general unbounded domain \( \Omega' \). However, under certain assumptions, we can find out the relationship between contraction factor \( \alpha \) and overlapping extent of \( \Omega'_1 \) and \( \Omega'_2 \). We define three prolate spheroids with the same semi-interfocal distance.
\[ \Gamma'_i = \{ (\mu, \theta, \phi) : \mu = \mu_i, \theta \in [0, \pi], \phi \in [0, 2\pi] \}, \quad i = 0, 1, 2, \quad (16) \]

where \( \mu_1 > \mu_2 > \mu_0 > 0 \).

We consider the following boundary value problem over domain \( \Omega'_1 \)
\[ \begin{aligned}
-\Delta u &= 0, \quad \text{in } \Omega'_1, \\
\mu = g_0, &\quad \text{on } \Gamma'_0, \\
\mu = g_1, &\quad \text{on } \Gamma'_1.
\end{aligned} \tag{17} \]

Suppose that
\[ g_i(\theta, \phi) = \sum_{n=0}^{+\infty} \sum_{m=-n}^{n} G_{nm}^{(i)} Y_{nm}(\theta, \phi), \quad i = 0, 1, \quad (18) \]

where
\[ G_{nm}^{(i)} = \int_{0}^{\pi} \int_{0}^{2\pi} g_i(\theta, \phi) Y_{nm}^*(\theta, \phi) \sin(\theta) d\theta d\phi, \quad i = 0, 1. \]

Then by the separation of variables, we can obtain the solution of (17)
\[ u(\mu, \theta, \phi) = \sum_{n=0}^{+\infty} \sum_{m=-n}^{n} \left( S(\mu, \mu_1) G_{nm}^{(0)} + S(\mu_0, \mu) G_{nm}^{(1)} \right) \frac{(S(\mu_0, \mu_1))}{S(\mu_0, \mu)} Y_{nm}(\theta, \phi), \quad (19) \]

where \( S(x, y) = P_n^m(\cosh x) Q_n^m(\cosh y) - P_n^m(\cosh y) Q_n^m(\cosh x) \). According to the property of the associated Legendre functions (Gradshteyn and Kyzhik 1980), we have the following lemma.

**Lemma 1** Let
\[ P_n^m(x) = \frac{d^{n+m}}{dx^{n+m}}(x^2 - 1)^n, \]

where \( n, m \) are both nonnegative integers. If \( 0 \leq m < n \), then \( P_n^m(x) \) has \( n - m \) different zeros \( -1 = \alpha_1 \leq \alpha_2 \leq \cdots \leq \alpha_{n-m} = 1 \) with \( \alpha_i = -\alpha_{n-m-(i-1)}, \quad i = 1, \ldots, n - m - 1. \)

**Lemma 2** If \( \mu > \mu_0 \), then we conclude
\[ \frac{P_n^m(\cosh \mu_0)}{P_n^m(\cosh \mu)} < \left( \frac{\cosh \mu_0}{\cosh \mu} \right)^n, \quad (20) \]

and
\[ \frac{Q_n^m(\cosh \mu_0)}{Q_n^m(\cosh \mu_0)} < \left( \frac{\cosh \mu_0}{\cosh \mu} \right)^n. \quad (21) \]
Proof. By the definition of \( P_m^n(x) \) we have

\[
P_m^n(\cosh \mu_0) = \left( \frac{\sinh \mu_0}{\sinh \mu} \right)^{m-2} \prod_{i=1}^{n-m} \frac{(\cosh \mu_0 - \alpha_i)}{(\cosh \mu - \alpha_i)}.
\]

For monotonicity, the following holds for \( i = 1, 2, \ldots, n-m \),

\[
\frac{(\cosh \mu_0 - \alpha_i)(\cosh \mu_0 - \alpha_{n-m-i+1})}{(\cosh \mu - \alpha_i)(\cosh \mu - \alpha_{n-m-i+1})} = \frac{(\cosh^2 \mu_0 - \alpha^2_i)}{(\cosh^2 \mu - \alpha^2_i)} < \frac{\cosh^2 \mu_0}{\cosh^2 \mu}.
\]

Hence,

\[
P_m^n(\cosh \mu_0) < \left( \frac{\cosh \mu_0}{\cosh \mu} \right)^n.
\]

\[ \square \]

On the other hand, (21) can be easily proved by the proposition of Huang and Yu (2006).

Theorem 2. Suppose \( g_0 \) is continuous on \( \Gamma_0 \) and (16) holds. If we apply the Schwarz alternating algorithm given in “Schwarz alternating algorithm based on NBR” section, then

\[
\sup_{\Omega_1} |u - u^{(2k+1)}| \leq C_1 \alpha^k
\]

and

\[
\sup_{\Omega_2} |u - u^{(2k+2)}| \leq C_2 \alpha^{k+1}
\]

hold true, the constant \( C_i (i = 1, 2) \) depend only on \( g_0 \) and \( \frac{Q_n^m(\cosh \mu_1)}{Q_n^m(\cosh \mu_0)} \) while

\[
0 < \alpha = \frac{Q_n^m(\cosh \mu_1)S(\mu_0, \mu_2)}{Q_n^m(\cosh \mu_2)S(\mu_0, \mu_1)} < 1.
\]

Proof. Similar to (8), so the solution of the unbounded problem outside of \( \Gamma_0 \) can be expressed as

\[
u(\mu, \theta, \varphi) = \sum_{n=0}^{\infty} \sum_{m=-n}^{n} \frac{Q_n^m(\cosh \mu)}{Q_n^m(\cosh \mu_0)} C_{nm}^{(0)} Y_{nm}(\theta, \varphi), \quad \mu \geq \mu_0.
\]

Let \( \tilde{u} = 0 \).

By using the algorithm, one has

\[
u(\mu, \theta, \varphi) - u^{(2k+1)}(\mu, \theta, \varphi)
\]

\[
= \sum_{n=0}^{\infty} \sum_{m=-n}^{n} \frac{Q_n^m(\cosh \mu_1)}{Q_n^m(\cosh \mu_0)} \left[ \frac{Q_n^m(\cosh \mu_1)S(\mu_0, \mu_2)}{Q_n^m(\cosh \mu_2)S(\mu_0, \mu_1)} \right]^k S(\mu_0, \mu) C_{nm}^{(0)} Y_{nm}(\theta, \varphi),
\]

where \( \mu_0 \leq \mu \leq \mu_1 \).
By defining
\[ \alpha = \frac{Q^m_n(\cosh \mu_1)S(\mu_0, \mu_2)}{Q^m_n(\cosh \mu_2)S(\mu_0, \mu_1)}, \]
we will show (24).

From Lemma 2, we have
\[ T(\mu) > \left( \frac{\cosh \mu}{\cosh \mu_0} \right)^{2n} > 1, \quad \mu > \mu_0, \]
and
\[ \frac{T(\mu_1)}{T(\mu_2)} > \left( \frac{\cosh \mu_1}{\cosh \mu_2} \right)^{2n} > 1, \]
where \( T(\mu) \) is defined as
\[ T(\mu) = \frac{P^m_n(\cosh \mu)Q^m_n(\cosh \mu_0)}{P^m_n(\cosh \mu_0)Q^m_n(\cosh \mu)}. \]

Since
\[ \alpha = \frac{T(\mu_2) - 1}{T(\mu_1) - 1} = 1 + \frac{T(\mu_2) - T(\mu_1)}{T(\mu_1) - 1}, \]
we obtain \( 0 < \alpha < 1 \). Hence, (22) is accomplished.

Obviously, (23) can be proved with similar process. Finally, the theorem is proved.

Remark The convergence is related on the overlapping part of \( \Omega_1' \) and \( \Omega_2' \). From Theorem 2, we conclude the larger the overlapping part is, the smaller the contraction factor \( \alpha \) will be, which identically means the faster the Schwarz alternating algorithm converging.

The error estimates of the algorithm
Denote \( \tilde{S}_h(\Omega_1') \) as the linear finite element space over \( \Omega_1' \), where the elements are partitioned as tetrahedrons. Let
\[ \tilde{S}_h(\Omega_1') = \left\{ v_h \in S_h(\Omega_1') | v_h |_{\Gamma_0 \cup \Gamma_1} = 0 \right\}. \]
\( \tilde{S}_h(\Omega_1') \) can be regarded as the subspace of \( V \) by zero extension. Therefore, we have the discrete Schwarz alternating algorithm as
\[ \begin{cases} 
\text{Find } u^{(2k+1)}_{1h} = u^{(2k+1)}_{1h} - u^{(2k)}_{1h} |_{\Omega_1'} \in \tilde{S}_h(\Omega_1') \quad \text{such that} \\
D_{\Omega_1'} (u^{(2k+1)}_{1h}, v) = -D_{\Omega_1'} (u^{(2k)}_{1h}, v), \quad \forall v \in \tilde{S}_h(\Omega_1'),
\end{cases} \quad (25) \]
and
\[ \begin{cases} 
\text{Find } w^{(2k+2)}_{2h} = u^{(2k+2)}_{2h} - u^{(2k+1)}_{2h} |_{\Omega_2} \in V_2 \quad \text{such that} \\
D_{\Omega_2'} (w^{(2k+2)}_{2h}, v) = -D_{\Omega_2} (u^{(2k+1)}_{2h}, v), \quad \forall v \in V_2,
\end{cases} \quad (26) \]
where
\[
\mathbf{u}_h^{(2k+1)} = \begin{cases} 
\mathbf{u}_1^{(2k+1)}, & \text{in } \Omega'_1 \\
\mathbf{u}_2^{(2k+1)}, & \text{in } \Omega'_2 
\end{cases}, \\
\mathbf{u}_h^{(2k+2)} = \begin{cases} 
\mathbf{u}_2^{(2k+1)}, & \text{in } \Omega'_2 \\
\mathbf{u}_2^{(2k+2)}, & \text{in } \Omega'_2 
\end{cases},
\]
and \(\mathbf{u}_h^{(0)} = \bar{u}\).

By Yu (2002), the solution of (26) can be written as
\[
\mathbf{u}_{2h}^{(2k+2)} = P\gamma \mathbf{u}_h^{(2k+1)},
\]
where \(P: \mathcal{H}^{1/2}(\Gamma'_2) \to \mathcal{W}_0^1(\Omega'_2)\) denotes Poisson integral operator and \(\gamma: \mathcal{H}^1(\Omega'_1) \to \mathcal{H}^{1/2}(\Gamma'_2)\) denotes trace operator. Combining with (27) and the discrete algorithm, one can easily have the following iteration value:
\[
\mathbf{u}_h^{(2k+1)} = \bar{u} + \begin{cases} 
\sum_{i=0}^{k} w_i^{(2i+1)} & \text{on } \Omega'_1 \setminus \Omega'_2 \\
\sum_{i=0}^{k} w_i^{(2i+1)} + \sum_{j=0}^{k-1} \left[ P\gamma w_j^{(2j+1)} - w_j^{(2j+1)} \right] & + \delta_k (P\gamma \bar{u} - \bar{u}) & \text{in } \Omega'_1 \setminus \Omega''_2, \\
\sum_{j=0}^{k-1} P\gamma w_j^{(2j+1)} & + \delta_k (P\gamma \bar{u} - \bar{u}) & \text{on } \Omega''_1 
\end{cases}
\]
and
\[
\mathbf{u}_h^{(2k+2)} = \bar{u} + \begin{cases} 
\sum_{i=0}^{k} w_i^{(2i+1)} & \text{on } \Omega'_1 \setminus \Omega'_2 \\
\sum_{i=0}^{k} w_i^{(2i+1)} + \sum_{j=0}^{k} \left[ P\gamma w_j^{(2j+1)} - w_j^{(2j+1)} \right] & + (P\gamma \bar{u} - \bar{u}) & \text{in } \Omega'_1 \setminus \Omega''_2, \\
\sum_{j=0}^{k-1} P\gamma w_j^{(2j+1)} & + (P\gamma \bar{u} - \bar{u}) & \text{on } \Omega'_1 
\end{cases}
\]
where
\[
\delta_k = \begin{cases} 
0, & \text{if } k = 0, \\
1, & \text{if } k > 0.
\end{cases}
\]
The term \(\sum_{j=0}^{k-1} \) vanishes at \( k = 0 \). Set
\[
A_h(\Omega'_2) = \left\{ P\gamma (v_h + \alpha \bar{u} + \beta w) - (v_h + \alpha \bar{u} + \beta w)|_{\partial \Omega'_2} \mid v_h \in \tilde{S}_h(\Omega'_2), \alpha, \beta \in R, w = u - \bar{u} \right\}.
\]

Similarly, we have the \(A_h(\Omega'_2)\) as the subspace of \(V\). Hence, \(A_h(\Omega'_2) \subset V_2 \subset V\). We have the following variational problem on the discrete space
\[
\begin{align*}
\text{Find } v_h^* & \in \mathcal{S}_h(\Omega_1') + A_h(\Omega_2') \quad \text{such that} \\
D_{\Omega_1'}(v_h^*, v_h) &= -D_{\Omega_1'}(\tilde{u}, v_h), \quad \forall v_h \in \mathcal{S}_h(\Omega_1') + A_h(\Omega_2').
\end{align*}
\] (28)

Obviously, the solution of (28) exists uniquely. Set \( u_h^* = v_h^* + \tilde{u} \). Similarly in Wu and Yu (2000b), we have the following error estimates.

**Theorem 3** For the discrete Schwarz alternating algorithm and the constant \( \alpha \) in Theorem 1, the following error estimates hold

\[
\begin{align*}
|u - u_h^{(2k+1)}|_1 & \leq C \|h + \alpha^{2k} |u_h^* - u_h^{(1)}|_1, \\
|u - u_h^{(2k+2)}|_1 & \leq C \|h + \alpha^{2k+2} |u_h^* - u_h^{(0)}|_1
\end{align*}
\]

**Numerical results**

Some numerical examples are computed to show the efficiency of our algorithm in this section. Using the method developed in “Schwarz alternating algorithm based on NBR” section. The linear elements is used in the computation of FEM. Computationally, we consider on three meshes: Mesh I, Mesh II and Mesh III. Each mesh is a refinement of its former one, especially as Mesh I is the primary. The refinement is defined as each of elements of the former mesh is divided into eight similar shape equally.

\( e \) and \( e_h \) denote the maximal error of all node functions on \( \Gamma_{1h} \) respectively, i.e.,

\[
e(k) = \sup_{P_i \in \Omega_{1h}} \left| u(P_i) - u_{1h}^{(2k+1)}(P_i) \right|, \\
e_h(k) = \sup_{P_i \in \Omega_{1h}} \left| u_{1h}^{(2k-1)}(P_i) - u_{1h}^{(2k+1)}(P_i) \right|
\]

\( q_h(k) \) is the rate of convergence, i.e.

\[
q_h(k) = \frac{e_h(k-1)}{e_h(k)}.
\]

Moreover, we use the relative maximum norm \( \|E_u\|_{\infty} \) of the errors between numerical solutions and the exact solutions:

\[
\|E_u\|_{\infty} = \frac{|u - u_h|_{\infty, \Omega_1}}{|u|_{\infty, \Omega_1}}.
\]

**Example 1** Set the cubic \( \Omega = \{(x, y, z) | |x| \leq 1, |y| \leq 1, |z| \leq 3\} \) and \( \Gamma_0 \) be its surface of \( \Omega \). The exact solution of problem (5) be

\[
u = \frac{x}{\sqrt{K_1}}/((x^2 + y^2)/K_1 + z^2/K_2)^{3/2}.
\]

Also \( g = u|_{\Gamma_0} \).

By the theoretical analysis, we take two confocal prolate ellipsoidal surfaces as artificial boundaries, which can be expressed as \( \Gamma_1 = \{(\mu, \theta, \phi) | \mu_1 = 1.5, \theta \in [0, \pi], \phi \in [0, 2\pi]\} \) and \( \Gamma_2 = \{(\mu, \theta, \phi) | \mu_2 = 1.25, \theta \in [0, \pi], \phi \in [0, 2\pi]\} \). And the semi-interfocal distance
\( f_1 = f_2 = 6 \). Moreover, we have \( K_1 = 1 \) and \( K_2 = 3 \). The efficient results are the case in Tables 1, 2 and Fig. 2.

From Table 1, we can see the convergence is really fast. Both \( e \) and \( e_h \) are smaller than them on former mesh. And the Fig. 2 shows us the errors converge rapidly. Both of them reveal that the fine the mesh, the faster the convergence. The numbers of Table 2 testify the remark in “The error estimates of the algorithm” section. By taking different \( \mu_1 \) and \( \mu_2 \), we chose 3 couples of artificial boundaries. Geometrically, the bigger the \( |\mu_1 - \mu_2| \), the bigger the overlapping domain. Within the same triangular partition (Mesh II), we conclude that the bigger the overlapping domain, the faster the convergence.

**Example 2** Generally, the \( \Omega \) is chosen as a prolate ellipsoidal. Set the semi-interfocal \( f_0 = 4 \) and \( \Gamma_0 = (\mu, \theta, \varphi) | \mu_0 = 0.5, \theta \in [0, \pi], \varphi \in [0, 2\pi] \). Set \( K_1 = K_2 = 1 \). Thus, the exact solution of problem (5) is

\[
u = \frac{1}{((x^2 + y^2)/K_1 + z^2/K_2)^{1/2}}.
\]

And \( g = u |_{\Gamma_0} \).

---

**Table 1 The relation between convergence rate and mesh: \( \mu_1 = 1.5, \mu_2 = 1.25 \)**

| Mesh | \( k \) | Number of iteration and corresponding values |
|------|--------|------------------------------------------------|
| I    | \( e \) | 2.4726E-1 | 9.0403E-2 | 5.4826E-2 | 8.0814E-3 | 8.0782E-3 | 8.0774E-3 |
|      | \( e_h \) | – | 2.8013E-2 | 3.6179E-3 | 7.2392E-4 | 1.5669E-4 | 3.6362E-4 |
|      | \( q_h \) | – | – | 77.4294 | 4.9977 | 4.6200 | 4.3092 |
| II   | \( e \) | 8.6794E-2 | 4.0215E-3 | 3.1259E-5 | 2.9243E-5 | 2.9104E-5 | 2.9100E-5 |
|      | \( e_h \) | – | 1.0366E-4 | 3.4624E-6 | 3.1645E-7 | 2.8591E-7 | 2.8503E-7 |
|      | \( q_h \) | – | – | 29.9437 | 10.9409 | 1.1068 | 1.0031 |
| III  | \( e \) | 1.6827E-3 | 9.2546E-4 | 7.4972E-5 | 7.492E-5 | 7.4792E-5 | 7.4753E-5 |
|      | \( e_h \) | – | 9.2858E-4 | 7.6389E-5 | 6.6424E-6 | 5.9675E-6 | 5.5203E-6 |
|      | \( q_h \) | – | – | 12.1564 | 11.5004 | 1.1131 | 1.0817 |

**Table 2 The relation between convergence rate and overlapping degree (Mesh II)**

| \( \mu_1 \) | \( \mu_2 \) | \( k \) | Number of iteration and corresponding values |
|-------------|-------------|--------|------------------------------------------------|
| 1.5         | 1.2         | \( e \) | 6.4726E-2 | 4.6532E-3 | 3.4571E-5 | 2.6119E-5 | 2.6084E-5 | 2.6002E-5 |
|             |             | \( e_h \) | – | 2.0222E-3 | 1.2045E-4 | 4.5076E-5 | 9.0874E-6 | 9.0244E-6 |
|             |             | \( q_h \) | – | – | 16.7890 | 3.8033 | 4.9290 | 1.0660 |
| 1.5         | 1.0         | \( e \) | 4.5186E-2 | 1.0521E-3 | 9.0705E-5 | 5.4413E-5 | 1.2218E-5 | 1.2103E-5 |
|             |             | \( e_h \) | – | 1.3736E-3 | 4.8697E-5 | 2.6640E-7 | 1.4184E-7 | 7.5349E-7 |
|             |             | \( q_h \) | – | – | 28.0516 | 18.3810 | 2.7813 | 2.8248 |
| 1.5         | 0.8         | \( e \) | 1.4825E-3 | 6.7734E-4 | 9.2125E-5 | 1.8249E-5 | 5.6719E-6 | 5.5017E-6 |
|             |             | \( e_h \) | – | 6.4936E-4 | 2.1429E-5 | 1.2093E-6 | 8.2674E-8 | 1.0827E-8 |
|             |             | \( q_h \) | – | – | 30.3022 | 17.7197 | 14.6287 | 7.6359 |
Similarly, we choose two artificial boundaries \( \Gamma_1 \) and \( \Gamma_2 \), which are both confocal with \( \Gamma_0 \) as \( f_1 = f_2 = f_0 = 6 \). Let \( \Gamma_1 = \{(\mu, \theta, \varphi) | \mu_1 = 2.5, \theta \in [0, \pi], \varphi \in [0, 2\pi]\} \) and \( \Gamma_2 = \{(\mu, \theta, \varphi) | \mu_2 = 2.0, \theta \in [0, \pi], \varphi \in [0, 2\pi]\} \). The corresponding results are the case in Tables 3, 4 and Fig. 3.

The data of Tables 3 and 4 show us a good convergence. And the analysis of the numbers can be similar to Example 1.

**Conclusions**

In this paper, we construct a Schwarz alternating algorithm for the anisotropic problem on the unbounded domain. The algorithm uses the DDM based on FEM and natural boundary element method. The theoretical analysis shows its convergence is first-order. Further, the rate of convergence is dependent on the overlapping domain. Some numerical examples testify the theoretical conclusions. We can investigate the Schwarz alternating algorithm for anisotropic problem with three different parameters over unbounded domain. Full details and results will be given in a future publication.
