Markov chains with heavy-tailed increments and asymptotically zero drift

Nicholas Georgiou*, Mikhail V. Menshikov*, Dimitri Petritis†, Andrew R. Wade*

Abstract

We study the recurrence/transience phase transition for Markov chains on $\mathbb{R}_+$, $\mathbb{R}$, and $\mathbb{R}^2$ whose increments have heavy tails with exponent in $(1, 2)$ and asymptotically zero mean. This is the infinite-variance analogue of the classical Lamperti problem. On $\mathbb{R}_+$, for example, we show that if the tail of the positive increments is about $c y^{-\alpha}$ for an exponent $\alpha \in (1, 2)$ and if the drift at $x$ is about $b x^{-\gamma}$, then the critical regime has $\gamma = \alpha - 1$ and recurrence/transience is determined by the sign of $b + c \pi \csc(\pi \alpha)$. On $\mathbb{R}$ we classify whether transience is directional or oscillatory, and extend an example of Rogozin & Foss to a class of transient martingales which oscillate between $\pm \infty$.

In addition to our recurrence/transience results, we also give sharp results on the existence/non-existence of moments of passage times.

Keywords: random walk; heavy tails; asymptotically zero drift; Lamperti’s problem; recurrence; transience; passage-time moments; Lyapunov functions.

1 Introduction

Lamperti’s problem describes how the asymptotic behaviour of a non-homogeneous random walk (Markov chain) $\xi_n$ on $\mathbb{R}_+$ whose increments have at least 2 moments is determined by the interplay between the increment moment functions

$$
\mu(x) := \mathbb{E}[\xi_{n+1} - \xi_n \mid \xi_n = x], \text{ and } s^2(x) := \mathbb{E}[(\xi_{n+1} - \xi_n)^2 \mid \xi_n = x].
$$

(1.1)

Lamperti [8–10] showed, among other things, that the critical regime for the recurrence or transience of $\xi_n$ is when $x \mu(x)$ is comparable to $s^2(x)$. For further background and

Markov chains with heavy-tailed increments and asymptotically zero drift

results, see [2, 12] and the references therein; the continued interest of Lamperti’s problem is due in part to its nature as a prototypical near-critical stochastic system.

In this paper, we study the heavy-tailed case where \( s^2(x) = \infty \), but \( \mu(x) \) is still well-defined. Under mild conditions, if \( \lim \sup_{x \to \infty} \mu(x) < 0 \) then the Markov chain on \( \mathbb{R}_+ \) is positive recurrent, while if \( \lim \inf_{x \to \infty} \mu(x) > 0 \) then the chain is transient (see e.g. Theorems 2.6.2 and 2.5.18 of [12]). Thus the case of central interest is the asymptotically zero drift regime where \( \mu(x) \to 0 \) as \( x \to \infty \).

We show that in the heavy-tailed case it is the interplay between the drift and the tails of the increments that determines the asymptotic behaviour. For instance, suppose

\[
P(\xi_{n+1} - \xi_n > y \mid \xi_n = x) \sim cy^{-\alpha}
\]

for some constants \( c > 0 \) and \( \alpha \in (1, 2) \), uniformly in \( x \). Here \( s^2(x) = \infty \), so Lamperti’s classification does not apply. We show (Theorem 2.1 below) that if \( \mu(x) \sim bx^{-\gamma} \) for some \( \gamma \in (0, 1) \), then the critical regime for recurrence and transience has \( \gamma = \alpha - 1 \), and in that case the process is transient if \( b + c\pi \csc(\pi \alpha) > 0 \) and recurrent if \( b + c\pi \csc(\pi \alpha) < 0 \).

As well as classifying recurrence and transience, we quantify the recurrent cases by determining which moments of return times to a bounded set are finite.

In addition to considering chains on \( \mathbb{R}_+ \), we also consider chains on \( \mathbb{R} \), and give an example on \( \mathbb{R}^2 \). On \( \mathbb{R} \), the situation is richer than on \( \mathbb{R}_+ \), and also than in the case where \( s^2(x) = O(1) \), since oscillatory transience can occur, when \( \lim \inf_{n \to \infty} \xi_n = -\infty \) and \( \lim \sup_{n \to \infty} \xi_n = +\infty \), but nevertheless \( \lim_{n \to \infty} |\xi_n| = \infty \). In the case of zero drift \( \mu(x) = 0 \), on \( \mathbb{R}_+ \) the chain is recurrent under mild conditions (see Example 2.5.6 of [12]) but on \( \mathbb{R} \) zero drift does not imply recurrence when \( s^2(x) = \infty \). Rogozin & Foss [13] gave a concrete example on \( \mathbb{R} \) of a zero-drift chain that is transient. The example has heavy-tailed jumps, with exponent \( \beta \in (1, 3/2) \), inwards to the origin from both the left and right half-lines. We show (Theorem 2.7 below) that the transience in this case is oscillatory and give general conditions for the behaviour of this kind, and also show how an asymptotically zero drift perturbs the picture. Again, in the recurrent cases we also study moments of passage times.

It is worth emphasising that for all our results the Markov property is not essential, and can be dispensed with without complicating the proofs, only the notation: cf. [8] or Chapter 3 of [12].

Apart from being interesting in their own right, stochastic processes on the positive half-line are important in the study of higher-dimensional processes via the Lyapunov function method (see e.g. [1, 4, 8, 12]): for a Markov chain \( \xi_n \) on \( \mathbb{R}^d \), the analysis typically proceeds by considering a one-dimensional projection \( \rho: \mathbb{R}^d \to \mathbb{R}_+ \) of the form \( \rho(x) := \|x\|^{\nu} \), for some positive constant \( \nu \); then \( \xi_n = \rho(\xi_n) \) is a (not necessarily Markov) process on \( \mathbb{R}_+ \) and recurrence/transience of \( \xi_n \) and \( \xi_0 \) coincide. As a first step into higher dimensions, we give an example of a heavy-tailed random walk on \( \mathbb{R}^2 \) and show how our approach can be used to provide conditions for recurrence and transience.

We briefly mention other relevant literature. The case of balanced tails (when the left and right jumps have the same exponent) has been studied in several papers by Sandrić in both discrete and continuum settings: see [14–16] and references therein. The only previous results on passage time moments that we know of are due to Doney [3] in the case of a zero-drift, spatially homogeneous random walk, and a subset of the authors [11]: these include some special cases of our results, but not the asymptotically zero drift regime. The case where even \( \mu(x) \) is not well-defined is quite different: see [7,11] and references therein.

Transience is typically quantified either via almost-sure growth bounds on trajectories or estimates of last-exit times. In a related context, results of both types are studied
in [7] for chains with non-integrable increments. Although not directly applicable, we believe the techniques used could be adapted to this setting.

Section 2 presents our main results, working in turn through the cases on $\mathbb{R}_+$ and $\mathbb{R}$, and finally giving an example on $\mathbb{R}^2$ and an open problem for a reflected random walk in a quadrant with heavy tails. Section 3 contains the tools that we need to determine the asymptotic behaviour of our processes via the method of Lyapunov functions. These include criteria for directional and oscillatory transience. Section 4 carries out the analysis of our Lyapunov functions. Section 5 contains the proofs of the main results. Technical results on integral computations needed for our Lyapunov-function estimates are collected in the Appendix.

2 Main results

2.1 Notation

For all the models in this paper, we use the following notation. Let $\mathbb{X}$ be an infinite, unbounded, measurable subset of $\mathbb{R}^d$ ($d \in \mathbb{N}$), equipped with its own $\sigma$-algebra $\mathcal{X}$. To avoid unnecessary complications with conditioning, we suppose in the sequel that the measurable space $(\mathbb{X}, \mathcal{X})$ is a standard Borel space. Let $\Xi := (\xi_n, n \in \mathbb{Z}_+)$ be a time-homogeneous $\mathbb{X}$-valued Markov process. Here and elsewhere, $\mathbb{N} := \{1, 2, 3, \ldots \}$ and $\mathbb{Z}_+ := \mathbb{N} \cup \{0\}$. The Markov process $\Xi$ is determined by its Markov kernel $P : \mathbb{X} \times \mathcal{X} \to [0, 1]$, specifying, as usual, the conditional law $P(x, A) = P(\xi_{n+1} \in A \mid \xi_n = x)$, for $x \in \mathbb{X}$ and $A \in \mathcal{X}$. By the Ionescu Tulcea theorem, the kernel $P$ and the law of $\xi_0$ uniquely determine a probability measure $P$ on the space $\mathbb{X}^{\mathbb{Z}_+}$ that can be disintegrated into the conditional measures $P_x[\cdot] = P(\cdot \mid \xi_0 = x)$ for all deterministic initial conditions. We write $E_x$ for the expectation corresponding to $P_x$. For $n \in \mathbb{Z}_+$, define the increment $\theta_{n+1} := \xi_{n+1} - \xi_n$. Consistently, the transition kernel of the chain is recovered from the law of $\theta_1$ given $\xi_0$; to ease notation, we write $\theta$ for $\theta_1$.

For $x \in \mathbb{R}$ we write $x_+ := x1\{x \geq 0\}$ and $x_- := -x1\{x < 0\}$.

2.2 Walks on the half line

We start with $\mathbb{X} \subseteq \mathbb{R}_+$. We say that $\Xi$ is transient if $\lim_{n \to \infty} \xi_n = \infty$, a.s., and that $\Xi$ is recurrent if $\liminf_{n \to \infty} \xi_n \leq r_0$, a.s., for some deterministic $r_0 \in \mathbb{R}_+$. For $a \in \mathbb{R}_+$ define $\tau_a := \min\{n \in \mathbb{Z}_+ : \xi_n \leq a\}$. If $\Xi$ is recurrent then $P_x[\tau_a < \infty] = 1$ for any $a > r_0$ and any $x$; if, moreover, $E_x[\tau_a] < \infty$ for all $a$ sufficiently large and any $x$, we say that $\Xi$ is positive recurrent, while if for all $a$ sufficiently large and all $x > a$ we have $E_x[\tau_a] = \infty$, then we say that $\Xi$ is null recurrent. We typically (but not always) assume the following.

(N) We have $\limsup_{n \to \infty} \xi_n = +\infty$, $P_x$-a.s. for all $x \in \mathbb{X}$.

(T$(\alpha, \beta, c)$) There exist constants $\alpha \in (1, 2)$, $\beta > \alpha$, $c > 0$, and $x_0 \in \mathbb{R}_+$ such that

$$\lim_{y \to \infty} \sup_{x \geq x_0} \left| y^{\alpha} P_x[\theta_+ > y] - c \right| = 0,$$

and

$$\sup_{x \geq x_0} E_x[\theta_+^\beta] < \infty.$$ 

Assumption (T$(\alpha, \beta, c)$) includes a precise version of (1.2), and means that the jumps to the right are ‘heavier’ than those to the left. Assumption (N) is non-confinement and rules out uninteresting cases; it is satisfied if, for example (a) $\Xi$ is an irreducible Markov chain on a locally finite $\mathbb{X}$ (see e.g. Corollary 2.1.10 in [12]); (b) for some $\varepsilon > 0$ the ellipticity condition $\inf_{x \geq 0} P_x[\theta \geq \varepsilon] \geq \varepsilon$ holds (Proposition 3.3.4 in [12]); or (c) in (T$(\alpha, \beta, c)$) we have $x_0 = 0$ (Proposition 5.2.1 of [12]).

We present a recurrence classification for $\Xi$ which is an analogue in the heavy-tailed setting of Lamperti’s classification [8, 10]. Recall from (1.1) that $\mu(x) := E_x[\theta]$.
Markov chains with heavy-tailed increments and asymptotically zero drift

**Theorem 2.1.** (i) Suppose that (N) and \((T_{\alpha,\beta,c})\) hold. Then \(\Xi\) is recurrent if

\[
\limsup_{x \to \infty} (x^{\alpha-1} \mu(x)) < c \pi |\cosec(\pi \alpha)|, \tag{2.1}
\]

and \(\Xi\) is transient if

\[
\liminf_{x \to \infty} (x^{\alpha-1} \mu(x)) > c \pi |\cosec(\pi \alpha)|, \tag{2.2}
\]

(ii) The chain \(\Xi\) is positive recurrent if there exist \(\alpha \in (1, 2)\) and \(\gamma < \alpha - 1\) such that

\[
\limsup_{x \to \infty} \mathbb{E}_x[|\theta|^\alpha] < \infty \quad \text{and} \quad \limsup_{x \to \infty} (x^\gamma \mu(x)) < 0.
\]

**Remarks 2.2.** (i) Note that \(\cosec(\pi \alpha) < 0\) for \(\alpha \in (1, 2)\), so part (i) says that the case \(\mu(x) \leq 0\) is recurrent, as one would expect, and shows what magnitude of positive drift must be added to achieve transience.

(ii) Part (i) says that the critical case where \(\mu(x) \sim bx^{1-\alpha}\) for some \(b < c \pi |\cosec(\pi \alpha)|\) is recurrent. In fact, this case is null-recurrent by Theorem 2.3(ii) below.

For the rest of the results that we present, we will also assume an asymptotic form for the drift. This is partly for simplicity of statement, but also necessary to get sharp transitions in our existence-of-moments results. The assumption is as follows.

\((D_{\gamma,b})\) There exist constants \(\gamma \geq 0\) and \(b \in \mathbb{R}\) such that \(\lim_{x \to \infty} (x^\gamma \mu(x)) = b\).

In the recurrent case, we can precisely quantify the recurrence by showing which moments of passage times exist. Here and elsewhere \(\Gamma\) denotes the (Euler) gamma function.

**Theorem 2.3.** Suppose that the Markov chain \(\Xi\) on \(\mathbb{R}_+\) satisfies \((T_{\alpha,\beta,c})\) and \((D_{\gamma,b})\). Let \(q > 0\). Then for all \(a\) sufficiently large and all \(x > a\), the following hold.

(i) If \(\gamma > \alpha - 1\) then \(\mathbb{E}_x[\tau_a^q] < \infty\) for \(q < 1/\alpha\), and \(\mathbb{E}_x[\tau_a^q] = \infty\) for \(q > 1/\alpha\).

(ii) If \(\gamma = \alpha - 1\) and \(b < c \pi |\cosec(\pi \alpha)|\), then \(\mathbb{E}_x[\tau_a^q] < \infty\) for \(q < \nu^*/\alpha\), and \(\mathbb{E}_x[\tau_a^q] = \infty\) for \(q > \nu^*/\alpha\), where \(\nu^* := \nu^*(\alpha, b, c)\) is the unique solution in \((0, \alpha)\) to

\[
\frac{b}{c} = (\nu^* - 1) \frac{\Gamma(1 - \alpha)\Gamma(\alpha - \nu^*)}{\Gamma(2 - \nu^*)}. \tag{2.3}
\]

(iii) If \(\gamma < \alpha - 1\) and \(b < 0\) then \(\mathbb{E}_x[\tau_a^q] < \infty\) for \(q < \frac{\alpha}{\gamma+1}\), and \(\mathbb{E}_x[\tau_a^q] = \infty\) for \(q \geq \frac{\alpha}{\gamma+1}\).

**Remarks 2.4.** (i) In parts (i) and (ii), we always have null recurrence (\(\mathbb{E}_x[\tau_0^q] = \infty\)), while in part (iii) we have positive recurrence (\(\mathbb{E}_x[\tau_0^q] < \infty\)).

(ii) If \(\Xi\) is a martingale satisfying assumptions (N) and \((T_{\alpha,\beta,c})\), then \((D_{\gamma,b})\) is automatically satisfied (for \(b = 0\) and any \(\gamma\)). Then \(\Xi\) is recurrent by Theorem 2.1(i), and Theorem 2.3(i) shows that the critical exponent for \(\tau_0\) is \(1/\alpha \in (1/2, 1)\); in the case of a spatially homogeneous random walk, this fact is essentially contained in a result of Doney [3]. In this sense, such a martingale with heavy tails away from the origin is more recurrent than simple symmetric random walk on \(\mathbb{R}_+\), which has critical exponent 1/2 (see, e.g., [12, Example 2.7.6]) but is still null recurrent.

### 2.3 Walks on the whole line: heavier outward tails

Now we turn to the case \(\Xi \subseteq \mathbb{R}\). We first suppose that for \(x > 0\), essentially the same conditions \((T_{\alpha,\beta,c})\) and \((D_{\gamma,b})\) as above hold, while for \(x < 0\) the symmetric version of those conditions holds, so that the outwards increment always has a heavier tail than the inwards one. This case closely corresponds to the walks on \(\mathbb{R}_+\) of the previous section. In full, the assumptions are as follows. We extend the definition of \(\mu(x) := \mathbb{E}_x[\theta]\) to \(x \in \mathbb{R}\).
Markov chains with heavy-tailed increments and asymptotically zero drift

(N') We have \( \limsup_{n \to \infty} |\xi_n| = +\infty \), a.s.

(T\textsubscript{out}\textsuperscript{α,β,c}) There exist constants \( \alpha \in (1, 2), \beta > \alpha, c > 0 \), and \( x_0 \in \mathbb{R}^+ \) such that
\[
\lim_{y \to \infty} \sup_{x \geq x_0} |y^\beta \mathbb{P}_x[\theta^\alpha > y] - c| = \lim_{y \to \infty} \sup_{x \leq -x_0} |y^\beta \mathbb{P}_x[\theta^- > y] - c| = 0,
\]
\[
\sup_{x \geq x_0} E_x[\theta^\beta_+] < \infty, \text{ and } \sup_{x \leq -x_0} E_x[\theta^\beta_-] < \infty.
\]

(D\textsubscript{γ,b}) There exist constants \( \gamma \geq 0 \) and \( b \in \mathbb{R} \) such that
\[
\lim_{x \to +\infty} (x^\gamma \mu(x)) = \lim_{x \to -\infty} (-x^\gamma \mu(x)) = b.
\]

For \( \Xi \) on \( \mathbb{R} \) we now say that \( \Xi \) is transient if \( \lim_{n \to \infty} |\xi_n| = \infty \), a.s., and recurrent if \( \liminf_{n \to \infty} |\xi_n| \leq r_0 \), a.s., for some \( r_0 \in \mathbb{R}^+ \). Setting \( \tau_0 := \min\{n \in \mathbb{Z}^+ : |\xi_n| \leq a\} \), positive and null recurrence are defined analogously to the case of \( \mathbb{R}^+ \). With transience, however, there are two distinct possibilities. We say that \( \Xi \) is oscillatory transient if, a.s.,
\[
\lim_{n \to \infty} |\xi_n| = \infty, \text{ and } -\infty = \liminf_{n \to \infty} \xi_n < \limsup_{n \to \infty} \xi_n = +\infty.
\]

On the other hand, we say that \( \Xi \) is directional transient if \( \lim_{n \to \infty} \xi_n \in \{-\infty, +\infty\} \), a.s. In the following theorem only directional transience appears; we will see instances of oscillatory transience in the next sections.

**Theorem 2.5.** Suppose that the Markov chain \( \Xi \) on \( \mathbb{R} \) satisfies \( \text{(N')}, \text{(T\textsubscript{out}α,β,c}), \text{ and (D\textsubscript{γ,b})} \). Then the following classification holds.

(i) If \( \gamma > \alpha - 1 \) then \( \Xi \) is null recurrent.

(ii) If \( \gamma < \alpha - 1 \) and \( b < 0 \) then \( \Xi \) is positive recurrent.

(iii) If \( \gamma < \alpha - 1 \) and \( b > 0 \) then \( \Xi \) is directional transient.

(iv) If \( \gamma = \alpha - 1 \) and \( b < c\pi|\cosec(\pi\alpha)| \) then \( \Xi \) is null recurrent.

(v) If \( \gamma = \alpha - 1 \) and \( b > c\pi|\cosec(\pi\alpha)| \) then \( \Xi \) is directional transient.

The moments result here is essentially the same as that on \( \mathbb{R}^+ \) from Theorem 2.3.

**Theorem 2.6.** Suppose that the Markov chain \( \Xi \) on \( \mathbb{R} \) satisfies \( \text{(T\textsubscript{out}α,β,c}) \) and \( (D\textsubscript{γ,b}) \). Then the statements in Theorem 2.3 hold verbatim, given that \( \tau_0 = \min\{n \in \mathbb{Z}^+ : |\xi_n| \leq a\} \).

### 2.4 Walks on the whole line: heavier inward tails

Again with \( X \subseteq \mathbb{R} \), we now flip things around so that the inwards increment has the heavier tail. Here more interesting phenomena occur: Our assumptions are as follows.

(T\textsubscript{in}α,β,c) There exist constants \( \beta \in (1, 2), \alpha > \beta, c > 0 \), and \( x_0 \in \mathbb{R}^+ \) such that
\[
\lim_{y \to \infty} \sup_{x \geq x_0} |y^\beta \mathbb{P}_x[\theta^- > y] - c| = \lim_{y \to \infty} \sup_{x \leq -x_0} |y^\beta \mathbb{P}_x[\theta^\alpha > y] - c| = 0,
\]
\[
\sup_{x \geq x_0} E_x[\theta^\beta_+] < \infty, \text{ and } \sup_{x \leq -x_0} E_x[\theta^\beta_-] < \infty.
\]

We also assume \( (D\textsubscript{γ,b}) \), and, where necessary, the following additional condition.

(T\textsuperscript{+}+) With \( \beta, c, \) and \( x_0 \) as in \( \text{(T\textsubscript{in}α,β,c}) \), there exists a constant \( \delta > 0 \) such that
\[
\sup_{x \geq x_0} |y^\beta \mathbb{P}_x[\theta^- > y] - c| = O(y^{-\delta}), \text{ and } \sup_{x \leq -x_0} |y^\beta \mathbb{P}_x[\theta^\alpha > y] - c| = O(y^{-\delta}).
\]
Markov chains with heavy-tailed increments and asymptotically zero drift

Our recurrence classification in this case is as follows.

**Theorem 2.7.** Suppose that the Markov chain $\Xi$ on $\mathbb{R}$ satisfies $(N')$, $(T^n_{\alpha,\gamma,b,c})$, and $(D'_\gamma,b)$. Then the following recurrence/transience criteria hold.

(i) If $\gamma > \beta - 1$ and $\beta > 3/2$ then $\Xi$ is null recurrent.

(ii) If $\gamma < \beta - 1$ and $b < 0$ then $\Xi$ is positive recurrent.

(iii) If $\gamma < \beta - 1$ and $b > 0$ then $\Xi$ is directional transient.

(iv) If $\gamma = \beta - 1$ and $b + c \pi \cot(\pi \beta) > 0$ then $\Xi$ is null recurrent.

If assumption $(T^+_\beta)$ is also satisfied, then the following transience criteria hold.

(v) If $\gamma > \beta - 1$ and $\beta < 3/2$ then $\Xi$ is oscillatory transient.

(vi) If $\gamma = \beta - 1$ and $b + c \pi \cot(\pi \beta) > 0$ then $\Xi$ is oscillatory transient.

**Remarks 2.8.** (i) For zero drift ($b = 0$), the phase transition at $\beta = 3/2$ was first observed by Rogozin & Foss [13], assuming that the law of $\theta$ depends only on the sign of $\xi_0$.

(ii) Note that $\cot(\pi \beta)$ is decreasing on $(1, 2)$, tends to $+\infty$ as $\beta \downarrow 1$, to $-\infty$ as $\beta \uparrow 2$, and changes sign at $\beta = 3/2$.

**Theorem 2.9.** Suppose that the Markov chain $\Xi$ on $\mathbb{R}^+$ satisfies $(T^n_{\alpha,\gamma,b,c})$ and $(D'_\gamma,b)$. Let $q > 0$. Then for all $a$ sufficiently large and all $x > a$, the following hold.

(i) If $\gamma > \beta - 1 > 1/2$ then $E_x[\tau^\gamma_0] < \infty$ for $q < \frac{2\alpha-3}{\beta}$, and $E_x[\tau^\gamma_0] = \infty$ for $q > \frac{2\alpha-3}{\beta}$.

(ii) If $\gamma = \beta - 1$ and $b + c \pi \cot(\pi \beta) < 0$, then $E_x[\tau^\gamma_0] < \infty$ for $q < \nu^*/\beta$, and $E_x[\tau^\gamma_0] = \infty$ for $q > \nu^*/\beta$, where $\nu^* := \nu^*(\beta, b, c)$ is the unique solution in $(0, \beta)$ to

$$\frac{b}{c} = \Gamma(\nu^*)(1 - \frac{1}{\nu^*})\frac{\Gamma(\nu^*)}{\Gamma(\nu^* - 1)} - \frac{\Gamma(\beta - \nu^*)}{\Gamma(\beta)}.$$ \hfill (2.4)

(iii) If $\gamma < \beta - 1$ and $b < 0$ then $E_x[\tau^\gamma_0] < \infty$ for $q < \frac{\beta}{\beta + 1}$, and $E_x[\tau^\gamma_0] = \infty$ for $q \geq \frac{\beta}{\beta + 1}$.

**Remark 2.10.** In the special case $\gamma = 0$ and assuming that no jumps away from the origin occur, the conclusion of Theorem 2.9(iii) coincides with Theorem 6(i) of [11].

### 2.5 Walks on the whole line: the balanced case

For the last of our models on $\mathbb{R}$, the inwards and outwards tail exponents coincide.

$(T^n_{\alpha,\gamma,b,c})$ There exist constants $\alpha \in (1, 2)$, $c > 0$, and $x_0 \in \mathbb{R}^+$ such that

$$\lim_{y \to -\infty} \sup_{x \geq x_0} \left| y^n P_x[\theta_+ > y] - c \right| = \lim_{y \to -\infty} \sup_{x \geq x_0} \left| y^n P_x[\theta_- > y] - c \right| = 0,$$

and

$$\lim_{y \to -\infty} \sup_{x \leq -x_0} \left| y^n P_x[\theta_+ > y] - c \right| = \lim_{y \to -\infty} \sup_{x \leq -x_0} \left| y^n P_x[\theta_- > y] - c \right| = 0.$$

We also assume $(D'_\gamma,b)$, and, where necessary, an analogue of $(T^+_\beta)$.

**Theorem 2.11.** Suppose that the Markov chain $\Xi$ on $\mathbb{R}$ satisfies $(N')$, $(T^n_{\alpha,\gamma,b,c})$, and $(D'_\gamma,b)$. Then the following recurrence/transience criteria hold.

(i) If $\gamma > \alpha - 1$ then $\Xi$ is null recurrent.

(ii) If $\gamma < \alpha - 1$ and $b > 0$ then $\Xi$ is positive recurrent.

(iii) If $\gamma < \alpha - 1$ and $b > 0$ then $\Xi$ is directional transient.
Theorem 2.12. Suppose that the Markov chain \( \Xi \) on \( \mathbb{R} \) satisfies (T_{\alpha,c}) and (D'_{\alpha,b}). Let \( q > 0 \). Then for all \( a \) sufficiently large and all \( x > a \), the following hold.

(i) If \( \gamma > \alpha - 1 \) then \( E_x[\tau_a^q] < \infty \) for \( q < 1 - \frac{1}{\alpha} \), and \( E_x[\tau_a^q] = \infty \) for \( q > 1 - \frac{1}{\alpha} \).

(ii) If \( \gamma = \alpha - 1 \) and \( b + c\pi \cot(\frac{\alpha}{2}) < 0 \), then \( E_x[\tau_a^q] < \infty \) for \( q < \nu^*/\alpha \), and \( E_x[\tau_a^q] = \infty \) for \( q > \nu^*/\alpha \), where \( \nu^* := \nu^*(\alpha, b, c) \) is the unique solution in \((0, \alpha)\) to
\[
\frac{b}{c} = (\nu^* - 1) \frac{\Gamma(1 - \alpha)\Gamma(\alpha - \nu^*)}{\Gamma(2 - \nu^*)} + \Gamma(\nu^*) \left( \frac{(1 - \alpha + \nu^*)\Gamma(1 - \alpha)}{\Gamma(2 - \alpha + \nu^*)} - \frac{\Gamma(\alpha - \nu^*)}{\Gamma(\alpha)} \right).
\]

(iii) If \( \gamma < \alpha - 1 \) and \( b < 0 \) then \( E_x[\tau_a^q] < \infty \) for \( q < \frac{a}{\gamma + 1} \), and \( E_x[\tau_a^q] = \infty \) for \( q \geq \frac{a}{\gamma + 1} \).

Remarks 2.13. (i) In the special case where the distribution of \( \theta \) is symmetric (so the drift is zero), the conclusion of Theorem 2.12(ii) coincides with Theorem 4(ii) of [11].

(ii) Sandrić [14, 16] considers symmetric or near-symmetric increment distributions, but allows the exponent \( \alpha(x) \) to vary with position \( x \in \mathbb{R} \). In particular, if \( \alpha(x) \in (1, 2) \) is bounded away from 1 and 2, then [14, 16] give sufficient conditions for recurrence, transience, and positive recurrence that generalize, under some additional conditions, the relevant parts of our Theorem 2.11 (see the discussion in [16, pp. 465–466]). Similar results for an analogous continuous-time model (Feller process) are obtained in [15].

2.6 Walks in higher dimensions: an example

We present a family of martingales on \( \mathbb{R}^2 \) with heavy-tailed jumps that contains both recurrent and transient walks. The example is deliberately simplistic for expository purposes; the phenomenon could certainly be reproduced for more naturally motivated random walks. Similarly, although the walks we describe here are 2-dimensional, this example can easily be extended to any dimension \( d \geq 2 \).

Let \( 0 \) denote the origin of \( \mathbb{R}^2 \). For \( x \in \mathbb{R}^2 \setminus \{0\} \) write \( u_x := x/\|x\| \), and write \( v_x \) for the unit vector perpendicular to \( u_x \) obtained by rotating \( u_x \) anticlockwise by \( \pi/2 \).

Our Markov chain \( \Xi \) on \( \mathbb{X} \subseteq \mathbb{R}^2 \) is constructed so that given \( \xi_0 = x \neq 0 \) the jump \( \theta \) is given by \( \theta = \chi u_x \theta^R + (1 - \chi)v_x \theta^T \), where \( \chi \in \{0, 1\} \), and \( \theta^R, \theta^T \in \mathbb{R} \) are independent of \( \chi \). If \( \chi = 1 \) we say that \( \theta \) is a radial jump, and if \( \chi = 0 \) we say that \( \theta \) is a transverse jump. We also assume that \( P_0[\theta = 0] < 1 \). We suppose that positive radial jumps are heavy tailed, that negative radial jumps have bounded moments, and that the transverse jumps are symmetric and also have heavy tails. Specifically, we assume the following.

(A) For all \( x \in \mathbb{R}^2 \setminus \{0\} \), \( P_x[\chi = 1] = p^R \in (0, 1) \) and \( P_x[\chi = 0] = p^T = 1 - p^R \).

(B) For all \( x \in \mathbb{R}^2 \setminus \{0\} \), \( E_x[\theta^R] = E_x[\theta^T] = 0 \).

(C) There exist constants \( \alpha \in (1, 2) \) and \( c^R \in (0, \infty) \) such that
\[
\lim_{y \to \infty} \sup_{x \in \mathbb{R}^2 \setminus \{0\}} \left| y^\alpha E_x[\theta^R > y] - c^R \right| = 0.
\]

(D) There exists a constant \( \beta > 0 \) such that
\[
\sup_{x \in \mathbb{R}^2 \setminus \{0\}} E_x[(\theta^R)^\beta] < \infty.
\]
Markov chains with heavy-tailed increments and asymptotically zero drift

(E) For all $x \in \mathbb{R}^3 \setminus \{0\}$ and all $y \in \mathbb{R}_+$, $P_x[\theta_T^T > y] = P_x[\theta_1^T > y]$, and there exists a constant $c_T \in (0, \infty)$ such that
\[
\lim_{y \to \infty} \sup_{x \in \mathbb{R}^3 \setminus \{0\}} \left| y^n P_x[\theta_T^T > y] - c_T \right| = 0.
\]

Now $\Xi$ is transient if $\lim_{n \to \infty} ||\xi_n|| = \infty$, a.s., and recurrent if $\liminf_{n \to \infty} ||\xi_n|| \leq r_0$, a.s., for some constant $r_0 \in \mathbb{R}_+$. Set $\tau_n := \min\{n \in \mathbb{Z}_+: ||\xi_n|| \leq a\}$.

**Theorem 2.14.** Suppose that the Markov chain $\Xi$ on $\mathbb{R}^2$ satisfies (A)–(E). Then the following classification holds.

(i) If $p^R c^R + 2p^T c^T \cos(\frac{n\theta}{2}) > 0$, then $\Xi$ is null recurrent.

(ii) If $p^R c^R + 2p^T c^T \cos(\frac{n\theta}{2}) < 0$, then $\Xi$ is transient.

Moreover, in case (i), for all $a$ sufficiently large we have $E_x[\tau_0^q] < \infty$ for $q < \nu^*/\alpha$ and $E_x[\tau_0^q] = \infty$ for $q > \nu^*/\alpha$ and $||x|| > a$, where $\nu^*$ is the unique solution in $(0, 1)$ to
\[
p^R c^R \Gamma(\alpha - \nu^*)/\Gamma(1 - \alpha) + p^T c^T \Gamma(\alpha - \nu^* - 1) / \Gamma(1 - \beta) = 0.
\]

**Remarks 2.15.** (i) The theorem shows how the balance between radial and transverse increments determines the recurrence behaviour of zero-drift random walks; for walks whose increments have two moments, the analogous phenomenon is driven by the increment covariance matrix, as described for example in [5] or [12, §4.2].

(ii) Since $\cos(\frac{n\theta}{2}) < 0$ for $\alpha \in (1, 2)$, there are walks exhibiting either behaviour for any $\alpha \in (1, 2)$. Indeed, both the ratio $c^R/c^T$ and the ratio $p^R/p^T$ can take any value in $(0, \infty)$, so for fixed $\alpha \in (1, 2)$ the walk is recurrent if either ratio is taken large enough, and transient if either ratio is taken small enough.

### 2.7 Walks in higher dimensions: an open problem

We finish this section with an open problem concerning a partially homogeneous random walk $\Xi$ on $\mathbb{X} = \mathbb{Z}_+^2$. Partition $\mathbb{Z}_+^2$ into sets $I := \mathbb{N}^2$, $A_1 := \mathbb{N} \times \{0\}$, $A_2 := \{0\} \times \mathbb{N}$, and $O := \{0\}$. Suppose that $P_x[\theta = \cdot | \theta]$ is determined only by which of $I$, $A_1$, $A_2$, $O$ contains $x$. Write $\theta = (\theta_1, \theta_2)$ in coordinates. Suppose that $P_x[\theta_j \geq -1] = 1$ for all $x \in I$ and $j \in \{1, 2\}$. Suppose also that $\sup_x E_x(||\theta||) < \infty$. Denote by $M_j = E[\theta | \xi_0 \in A_j]$ the mean drift vectors on the axes, and by $M_0 = E[\theta | \xi_0 \in I]$ the drift in the interior.

If $M_0 \neq 0$ the problem can be essentially classified in terms of $M_0, M_1,$ and $M_2$: see pp. 39–41 of [4]. The most subtle case has $M_0 = 0$. If $\sup_x E_x(||\theta||^p) < \infty$ for some $p > 2$, then also important is the covariance of $\theta$ in region $I$: see pp. 56–58 of [4], or [1].

What about when $M_0 = 0$ but the second moment is infinite? Concretely, suppose that for $c_1, c_2 > 0$ and $\alpha_1, \alpha_2 \in (1, 2)$, for $j \in \{1, 2\}$ and $y \in \mathbb{N}$,
\[
P[\theta_j = y | \xi_0 \in I] = (c_j + o(1))y^{-1-\alpha_j}, \text{ as } y \to \infty.
\]

Thus the jumps of $\Xi$ are heavy-tailed away from the axes, but bounded towards the axes.

**Problem 2.16.** Classify the recurrence and transience of $\Xi$.

The answer to Problem 2.16 may well depend on $M_1, M_2$, the $c_j$ and $\alpha_j$, and also on some analogue of the increment covariance matrix in the heavy-tailed setting.

### 3 Semimartingale criteria for real-valued processes

Central in proving our main results is the Lyapunov function methodology: we find a function $f$ so that $f(\xi_n)$ satisfies a suitable semimartingale condition, which implies the
desired properties of $\Xi$. In this section we collect the semimartingale criteria that we need; mostly this involves presenting known results, but a little work is needed to get statements in the form that we want for establishing directional or oscillatory transience.

All of these results are stated for a real-valued stochastic process $(X_n, n \in \mathbb{Z}_+)$ adapted to a filtration $(\mathcal{F}_n, n \in \mathbb{Z}_+)$. This generality, without assuming that $X_n$ is Markov, is useful so that we can apply the results to e.g. $X_n = \|\xi_n\|$ for $\xi_n \in \mathbb{R}^2$ the model in Section 2.6. First we present recurrence and transience criteria for processes on $\mathbb{R}_+$; these results are Theorems 3.5.8 and 3.5.6(ii) in [12].

**Lemma 3.3** (Directional transience criterion). Suppose that $(X_n)$ is an $(\mathcal{F}_n)$-adapted process taking values in $\mathbb{R}_+$ and $\lim \sup_{n \to \infty} X_n = \infty$, a.s. Let $f : \mathbb{R}_+ \to \mathbb{R}_+$ be such that $f(x) \to \infty$ as $x \to \infty$ and $\lim_{x \to \infty} f(x) < \infty$. Suppose also that there exists $x_1 \in \mathbb{R}_+$ for which, for all $n \geq 0$,

$$E[f(X_{n+1}) - f(X_n) \mid \mathcal{F}_n] \leq 0, \text{ on } \{X_n > x_1\};$$

$$E[f(X_{n+1}) - f(X_n) \mid \mathcal{F}_n] \leq C, \text{ on } \{X_n \leq x_1\}.$$

Then $\lim \inf_{n \to \infty} X_n \leq x_1$, a.s.

**Lemma 3.4** (Transience criterion on $\mathbb{R}$). Suppose that $(X_n)$ is an $(\mathcal{F}_n)$-adapted process taking values in $\mathbb{R}$ and $\lim \sup_{n \to \infty} \|X_n\| = \infty$, a.s. Let $f : \mathbb{R} \to \mathbb{R}_+$ be such that $\lim_{x \to \infty} f(x) = \lim_{x \to -\infty} f(x) = \infty$ and $E f(X_0) < \infty$. Suppose also that there exists $x_1 \in \mathbb{R}_+$ for which, for all $n \geq 0$,

$$E[f(X_{n+1}) - f(X_n) \mid \mathcal{F}_n] \leq 0, \text{ on } \{|X_n| > x_1\};$$

$$E[f(X_{n+1}) - f(X_n) \mid \mathcal{F}_n] \leq C, \text{ on } \{|X_n| \leq x_1\}.$$

Then $\lim \inf_{n \to \infty} |X_n| \leq x_1$, a.s.

**Lemma 3.5** (Directional transience criterion). Suppose that $(X_n)$ is an $(\mathcal{F}_n)$-adapted process taking values in $\mathbb{R}$ and $\lim \sup_{n \to \infty} |X_n| = \infty$, a.s. Let $f : \mathbb{R} \to \mathbb{R}_+$ be such that $\lim_{x \to \infty} f(x) = \lim_{x \to -\infty} f(x) = 0$ and $\inf_{y \leq x} f(y) > 0$ for any $x \in \mathbb{R}_+$. Suppose also that there exists $x_1 \in \mathbb{R}_+$ for which, for all $n \geq 0$,

$$E[f(X_{n+1}) - f(X_n) \mid \mathcal{F}_n] \leq 0, \text{ on } \{|X_n| > x_1\};$$

$$E[f(-X_{n+1}) - f(-X_n) \mid \mathcal{F}_n] \leq 0, \text{ on } \{X_n < -x_1\}.$$
Markov chains with heavy-tailed increments and asymptotically zero drift

Then \( \lim_{n \to \infty} X_n \in \{-\infty, +\infty\} \), a.s.

**Lemma 3.6** (Oscillatory transience criterion). Suppose that \((X_n)\) is an \((F_n)\)-adapted process taking values in \(\mathbb{R}\) and \(\lim_{n \to \infty} |X_n| = \infty\), a.s. Let \(f : \mathbb{R} \to \mathbb{R}_+\) be such that \(\lim_{x \to +\infty} f(x) = \infty\) and \(E f(X_0) < \infty\). Suppose that there exist \(x_1 \in \mathbb{R}\) and \(C < \infty\) for which, for all \(n \geq 0\),

\[
E[f(X_{n+1}) - f(X_n) \mid F_n] \leq 0, \text{ on } \{X_n < x_1\};
\]

\[
E[f(X_{n+1}) - f(X_n) \mid F_n] \leq C, \text{ on } \{X_n \leq x_1\};
\]

\[
E[f(-X_{n+1}) - f(-X_n) \mid F_n] \leq 0, \text{ on } \{X_n < -x_1\};
\]

\[
E[f(-X_{n+1}) - f(-X_n) \mid F_n] \leq C, \text{ on } \{X_n \geq -x_1\}.
\]

Then \( \liminf_{n \to \infty} X_n = -\infty \) and \( \limsup_{n \to \infty} X_n = +\infty \), a.s.

We give the proofs of these two results. A key step in the proof of Lemma 3.5 is the following hitting probability estimate.

**Lemma 3.7.** Suppose that \((X_n)\) is an \((F_n)\)-adapted process taking values in \(\mathbb{R}\). Let \(f : \mathbb{R} \to \mathbb{R}_+\) be such that \(\sup_{x \in \mathbb{R}} f(x) < \infty\) and \(\lim_{x \to +\infty} f(x) = 0\). Suppose that there exists \(x_2 \in \mathbb{R}\) for which \(\inf_{y \leq x_2} f(y) > 0\) and, for all \(n \geq 0\),

\[
E[f(X_{n+1}) - f(X_n) \mid F_n] \leq 0, \text{ on } \{X_n > x_2\}.
\]

Then for any \(\varepsilon > 0\) there exists \(x \in (x_2, \infty)\) for which, for all \(n \geq 0\),

\[
P\left( \inf_{m \geq n} X_m \geq x \middle| F_n \right) \geq 1 - \varepsilon, \text{ on } \{X_n > x\}.
\]

**Proof.** The idea is standard: the proof of Lemma 3.5.7 of [12], although that result is stated for processes on \(\mathbb{R}_+\), carries over directly to this case.

**Proof of Lemma 3.5.** Under the conditions of the lemma, it is clear that the hypotheses of Lemma 3.7 hold for any \(x_2\) with \(x_2 > x_1 > 0\) and for both \((X_n)\) and \((-X_n)\). So for any \(x_2 > x_1\) and \(\varepsilon > 0\) there exists \(x \in (x_2, \infty)\) for which, for all \(n \geq 0\),

\[
P\left( \inf_{m \geq n} X_m \geq x \middle| F_n \right) \geq 1 - \varepsilon, \text{ on } \{X_n > x\}, \text{ and}
\]

\[
P\left( \inf_{m \geq n} -X_m \geq x \middle| F_n \right) \geq 1 - \varepsilon, \text{ on } \{-X_n > x\}.
\]

In other words,

\[
P\left( \left\{ \inf_{m \geq n} X_m \geq x_2 \right\} \cup \left\{ \sup_{m \geq n} X_m \leq -x_2 \right\} \middle| F_n \right) \geq 1 - \varepsilon, \text{ on } \{|X_n| > x\}.
\]

Now, let \(\sigma_x = \min\{n \in \mathbb{Z}_+ : |X_n| > x\}\). Then, on \(\{\sigma_x < \infty\}\),

\[
P\left( \left\{ \inf_{m \geq \sigma_x} X_m \geq x_2 \right\} \cup \left\{ \sup_{m \geq \sigma_x} X_m \leq -x_2 \right\} \middle| F_{\sigma_x} \right) \geq 1 - \varepsilon, \text{ a.s.}
\]

But if \(\sigma_x < \infty\) and either \(X_m \geq x_2\) for all \(m \geq \sigma_x\) or \(X_m \leq -x_2\) for all \(m \geq \sigma_x\), we have that \(\lim \inf_{m \to \infty} X_m \geq x_2\) \(\cup\) \(\lim \sup_{m \to \infty} X_m \leq -x_2\) occurs. Thus

\[
P\left[ \left\{ \lim \inf_{m \to \infty} X_m \geq x_2 \right\} \cup \left\{ \lim \sup_{m \to \infty} X_m \leq -x_2 \right\} \right]
\]

\[
\geq E \left[ P\left[ \left\{ \inf_{m \geq \sigma_x} X_m \geq x_2 \right\} \cup \left\{ \sup_{m \geq \sigma_x} X_m \leq -x_2 \right\} \middle| F_{\sigma_x} \right] \mathbf{1}\{\sigma_x < \infty\} \right]
\]

\[
\geq (1 - \varepsilon) P[\sigma_x < \infty].
\]
Markov chains with heavy-tailed increments and asymptotically zero drift

Given \( \limsup_{n \to \infty} |X_n| = \infty \), a.s., we have \( \mathbb{P}[\sigma_x < \infty] = 1 \), and since \( \epsilon > 0 \) was arbitrary,

\[
\mathbb{P}\left[ \left\{ \lim_{m \to \infty} \inf X_m \geq x_2 \right\} \cup \left\{ \lim_{m \to \infty} \sup X_m \leq -x_1 \right\} \right] = 1.
\]

Then, since \( x_2 > x_1 \) was also arbitrary, with the fact that \( \liminf_{n \to \infty} X_m \geq x \) and \( \limsup_{n \to \infty} X_m \leq -y \) are mutually exclusive for \( x, y > 0 \), the result follows. \( \square \)

Now we turn to the proof of Lemma 3.6. First, we give a variation on Lemma 3.1 for processes on \( \mathbb{R} \); the proof from [12, p. 113] carries across directly to this setting.

**Lemma 3.8.** Suppose that \( (X_n) \) is an \((\mathcal{F}_n)\)-adapted process taking values in \( \mathbb{R} \). Let \( f : \mathbb{R} \to \mathbb{R}_+ \) be such that \( f(x) \to \infty \) as \( x \to +\infty \) and \( \mathbb{E} f(X_0) < \infty \). Suppose that there exist \( x_1 \in \mathbb{R} \) and \( C < \infty \) for which, for all \( n \geq 0 \),

\[
\mathbb{E}[f(X_{n+1}) - f(X_n) \mid \mathcal{F}_n] \leq 0, \text{ on } \{X_n > x_1\}, \text{ a.s.};
\]

\[
\mathbb{E}[f(X_{n+1}) - f(X_n) \mid \mathcal{F}_n] \leq C, \text{ on } \{X_n \leq x_1\}, \text{ a.s.}
\]

Then

\[
\mathbb{P}\left[ \left\{ \limsup_{n \to \infty} X_n < \infty \right\} \cup \left\{ \liminf_{n \to \infty} X_n \leq x_1 \right\} \right] = 1.
\]

In particular, \( \liminf_{n \to \infty} X_n < \infty \), a.s.

**Proof of Lemma 3.6.** Since \( \lim_{n \to \infty} |X_n| = \infty \), a.s., we have that

\[
\mathbb{P}\left[ \left\{ \lim_{n \to \infty} X_n = +\infty \right\} \cup \left\{ \lim_{n \to \infty} X_n = -\infty \right\} \cup \left\{ \limsup_{n \to \infty} X_n = \limsup_{n \to \infty} (-X_n) = \infty \right\} \right] = 1.
\]

But Lemma 3.8 applied to \( (X_n) \) implies that \( \liminf_{n \to \infty} X_n < \infty \), a.s., and hence \( X_n \not\to +\infty \), a.s. Similarly, the lemma applied to \( (-X_n) \) implies that \( X_n \not\to -\infty \), a.s., and therefore \( \lim_{n \to \infty} |X_n| = \limsup_{n \to \infty} X_n = \limsup_{n \to \infty} (-X_n) = \infty \), a.s. \( \square \)

Finally, we state two results that provide general conditions for the existence and non-existence of certain moments of passage times. These are reformulations of Theorem 1 and Corollary 1 of [1] (see also [11, §6.1] or [12, §2.7]).

**Lemma 3.9.** Let \( (Y_n) \) be an integrable \((\mathcal{F}_n)\)-adapted stochastic process, taking values in an unbounded subset of \( \mathbb{R}_+ \), with \( Y_0 = y_0 \) fixed. For \( x > 0 \), let \( \sigma_x := \inf \{ n \geq 0 : Y_n \leq x \} \). Suppose that there exist \( \delta > 0, x > 0 \) and \( \kappa < 1 \) such that for any \( n \geq 0 \),

\[
\mathbb{E}[Y_{n+1} - Y_n \mid \mathcal{F}_n] \leq -\delta Y_n^\kappa, \text{ on } \{n < \sigma_x\}.
\] \( (3.1) \)

Then for any \( p \in [0,1/(1-\kappa)) \), \( \mathbb{E}[\sigma_x^p] < \infty \).

**Lemma 3.10.** Let \( (Y_n) \) be an integrable \((\mathcal{F}_n)\)-adapted stochastic process, taking values in an unbounded subset of \( \mathbb{R}_+ \), with \( Y_0 = y_0 \) fixed. For \( x > 0 \), let \( \sigma_x := \inf \{ n \geq 0 : Y_n \leq x \} \). Suppose that there exist \( C_1, C_2 > 0, x > 0, p > 0 \) and \( r > 1 \) such that for any \( n \geq 0 \), on \( \{n < \sigma_x\} \) the following hold:

\[
\mathbb{E}[Y_{n+1} - Y_n \mid \mathcal{F}_n] \geq -C_1;
\] \( (3.2) \)

\[
\mathbb{E}[Y_{n+1} - Y_n^r \mid \mathcal{F}_n] \leq C_2 Y_n^{-r-1};
\] \( (3.3) \)

\[
\mathbb{E}[Y_{n+1}^p - Y_n^p \mid \mathcal{F}_n] \geq 0.
\] \( (3.4) \)

Then for any \( q > p \), \( \mathbb{E}[\sigma_x^q] = \infty \) for \( y_0 > x \).
4 Lyapunov function calculations

4.1 Preliminaries

For the case $X \subseteq \mathbb{R}_+$, we use the Lyapunov function $f_0 : \mathbb{R}_+ \to \mathbb{R}_+$ defined for $\nu \in \mathbb{R}$ by

$$f_0(x) := f_0'(x) := \begin{cases} x^\nu & \text{for } x \geq 1, \\ 1 & \text{for } 0 \leq x < 1. \end{cases}$$

The truncation at 1 is only necessary for $\nu < 0$, but for convenience we define $f_0$ as above for all $\nu \in \mathbb{R}$. For processes on $\mathbb{R}$ we will use two related, but different, extensions of $f_0$ to the whole of $\mathbb{R}$. These are defined for $\nu \in \mathbb{R}$ as follows.

$$f_1(x) := f_1'(x) := \begin{cases} x^\nu & \text{for } x \geq 1, \\ 1 & \text{for } x < 1, \end{cases} \quad \text{and} \quad f_2(x) := f_2'(x) := \begin{cases} |x|^\nu & \text{for } |x| \geq 1, \\ 1 & \text{for } |x| < 1. \end{cases}$$

The ‘two-sided’ function $f_2$ will be used to establish recurrence (with $\nu > 0$) and transience ($\nu < 0$); the ‘one-sided’ function $f_1$ will be used for distinguishing between directional ($\nu < 0$) and oscillatory ($\nu > 0$) transience. Define

$$D_i(x) := D_i'(x) := E[f_i(\xi_{n+1}) - f_i(\xi_n) | \xi_n = x]. \quad (4.1)$$

Our first estimate for the $D_i$ will be useful when the drift is dominant. In the calculations here and in the rest of the paper, various constants $C < \infty$ will appear, whose precise value is not important, and may change from line to line.

**Lemma 4.1.** Suppose that either (i) $X \subseteq \mathbb{R}_+$, or (ii) $X \subseteq \mathbb{R}$. In either case, suppose that, for some $\alpha \in (1,2)$, $\limsup_{x \to +\infty} E_x[|\theta|^{\alpha}] < \infty$. Let $\epsilon > 0$. Then for any $\nu \in (-\epsilon, \alpha)$, the following asymptotics hold with $i = 0$ in case (i) and with $i = 1$ in case (ii).

$$D_i(x) = \nu x^{\nu-1} E_x[\theta] + O(x^{\nu-\alpha+\epsilon}), \quad \text{as } x \to +\infty.$$  

**Proof.** Suppose that either (i) or (ii) holds, and take $i = 0$ or $i = 1$ respectively. Let $\gamma \in (0,1)$, to be specified later. By assumption, $E_x[|\theta|^{\alpha}] \leq C$ for constant $C < \infty$ and all $x$ large enough; suppose that $x \geq 1$ is such an $x$. For $\nu < 0$, $f_1(x) \in [0,1]$ for all $x$ (in $\mathbb{R}_+$ or $\mathbb{R}$, as appropriate), while for $\nu > 0$, $f_1(x)$ is non-decreasing. Moreover, for all $x \geq 1, \theta \geq x^\gamma$ implies that $x + \theta \leq 2\theta^{1/\gamma}$. These facts imply the bounds

$$E_x[|f_i(x + \theta) - f_i(x)| \mathbb{1}[|\theta| \geq x^\gamma]] \leq \begin{cases} C E_x[|\theta|^{\nu/\gamma} \mathbb{1}[|\theta| \geq x^\gamma]] & \text{for } \nu > 0, \\ P_x[|\theta| \geq x^\gamma] & \text{for } \nu < 0. \end{cases}$$

Fix $\epsilon > 0$ and $\nu \in (-\epsilon, \alpha)$. For $\nu < 0$, Markov’s inequality with the moments assumption yields $P_x[|\theta| \geq x^\gamma] = O(x^{-\alpha}) = O(x^{\nu-\alpha+\epsilon})$, provided that we take $\gamma > 1 - \frac{\epsilon}{\alpha}$, which we may since $\nu + \epsilon > 0$. If $\nu > 0$, take $\gamma > \frac{\epsilon}{\alpha}$ so that

$$E_x[|\theta|^{\nu/\gamma} \mathbb{1}[|\theta| \geq x^\gamma]] \leq x^{\nu-\alpha} E_x[|\theta|^{\alpha}] = O(x^{\nu-\alpha+\epsilon}),$$

provided that $\gamma > 1 - \frac{\epsilon}{\alpha}$. Thus in either case we have

$$E_x[|f_i(x + \theta) - f_i(x)| \mathbb{1}[|\theta| \geq x^\gamma]] = O(x^{\nu-\alpha+\epsilon})$$

for a suitable $\gamma \in (0,1)$. On the other hand, for all $x$ sufficiently large,

$$E_x[|f_i(x + \theta) - f_i(x)| \mathbb{1}[|\theta| < x^\gamma]] = x^{\nu} E_x \left[ \left( (1 + x^{-1})^\nu - 1 \right) \mathbb{1}[|\theta| < x^\gamma] \right].$$

The Taylor expansion $(1 + z)^\nu = 1 + \nu z + \frac{1}{2} \nu (\nu - 1) z^2 (1 + \phi z)^{\nu - 2}$, valid for $z > -1$ and where $\phi = \phi(z) \in [0, 1]$, implies that, for all $x$ sufficiently large,

$$|E_x[|f_i(x + \theta) - f_i(x)| \mathbb{1}[|\theta| < x^\gamma]]| \leq x^{\nu - 2 + (2 - \alpha)\nu} E_x[|\theta|^{\alpha}],$$

which is $o(x^{\nu-\alpha})$ since $\gamma < 1$. Noting that $E_x[|\theta| \mathbb{1}[|\theta| \geq x^\gamma]] \leq x^{\gamma-\alpha} E_x[|\theta|^{\alpha}]$ and that $\gamma - \alpha < 1 - 1 + \epsilon$ provided that $\gamma > 1 - \frac{\epsilon}{\alpha - 1}$, the result follows.
4.2 Lyapunov function on the half line

Lemma 4.1 is only useful for large drift; otherwise, we must use the tail assumptions on the increments to evaluate more precisely the other contributions to \( D_t \). First we consider \( X \subseteq \mathbb{R}^+ \); the calculations in this setting will be a model for the other cases. Set

\[
\kappa_0(\nu) := \kappa_0(\alpha, \nu) := (1 - \nu) \frac{\Gamma(\alpha - \nu) \Gamma(1 - \alpha)}{\Gamma(2 - \nu)}.
\]

(4.2)

Note that \( \nu \mapsto \kappa_0(\nu) \) is continuous on \((-\infty, \alpha)\).

**Lemma 4.2.** Suppose that the random walk \( \Xi \) on \( \mathbb{R}^+ \) satisfies \((T_{\alpha, \beta, c})\). Then, for any \( \nu \) for which \( \alpha - \beta < \nu < \alpha \), as \( x \to \infty \),

\[
D_0(x) = \nu x^{\nu - 1} \mathbb{E}_x[\theta] + \nu x^{\nu - \alpha} \kappa_0(\nu) + o(x^{\nu - \alpha}).
\]

**Proof.** The case \( \nu = 0 \) is trivially true, since \( f_0(\xi_{n+1}) - f_0(\xi_n) \) is then identically zero. For \( \nu \neq 0 \), the fact that \( g(\theta) = g(\theta_+) + g(-\theta_-) \) for any function with \( g(0) = 0 \) yields

\[
D_0(x) = \mathbb{E}_x[f_0(x + \theta_+) - f_0(x)] + \mathbb{E}_x[f_0(x - \theta_) - f_0(x)].
\]

(4.3)

In the case \( \nu = 1 \), for \( x \geq 1 \) we can write (4.3) as

\[
D_0(x) = \mathbb{E}_x[\theta_+] - \mathbb{E}_x[\theta_- 1\{\theta_- \leq x - 1\}] + \mathbb{E}_x[(1 - x) 1\{\theta_- > x - 1\}]
\]

\[
= \mathbb{E}_x[\theta] + \mathbb{E}_x[(\theta_+ - (x - 1)) 1\{\theta_- > x - 1\}],
\]

(4.4)

and therefore

\[
0 \leq D_0(x) - \mathbb{E}_x[\theta] \leq \mathbb{E}_x[\theta_- 1\{\theta_- > x - 1\}].
\]

For \( x > x_0 \), from the \( \beta \)-moments bound in \((T_{\alpha, \beta, c})\) and the fact that \( \beta > \alpha > 1 \), we get

\[
\mathbb{E}_x[\theta_- 1\{\theta_- > x - 1\}] \leq (x - 1)^{1 - \beta} \mathbb{E}[\theta^\beta 1\{\theta_- > x - 1\}] \leq C(x - 1)^{1 - \beta},
\]

and therefore \( D_0(x) = \mathbb{E}_x[\theta] + o(x^{1 - \alpha}) \), as claimed.

Now suppose that \( \alpha - \beta < \nu < \alpha \) with \( \nu \notin \{0, 1\} \). For any \( x \geq 1 \), we can write

\[
\mathbb{E}_x[f_0(x + \theta_+) - f_0(x)] = x^{\nu} \mathbb{E}_x[A_1 + A_2 + A_3],
\]

where we define the random variables

\[
A_1 = ((1 + \theta_+/x)^\nu - 1 - \nu \theta_+/x) 1\{\theta_+ \leq x^\epsilon\},
\]

\[
A_2 = ((1 + \theta_+/x)^\nu - 1 - \nu \theta_+/x) 1\{\theta_+ > x^\epsilon\},
\]

\[
A_3 = \nu \theta_+/x,
\]

where \( \epsilon \in (0, \frac{2 - \alpha}{2}) \) is fixed.

For \( \mathbb{E}_x[A_1] \), we use the Taylor expansion \((1 + z)^\nu = 1 + \nu z + \frac{1}{2} \nu (\nu - 1) z^2 (1 + \phi z)^{\nu - 2}\) for some \( \phi = \phi(z) \in [0, 1] \), valid for \( z > -1 \), and the fact that \( \nu < \alpha < 2 \) to write

\[
|((1 + z)^\nu - 1 - \nu z| \leq \begin{cases} \frac{1}{2} |\nu (\nu - 1)| z^2 & \text{for } z \geq 0, \\ \frac{1}{2} |\nu (\nu - 1)| z^2 (1 + z)^{\nu - 2} & \text{for } -1 < z < 0. \end{cases}
\]

(4.5)

Hence

\[
|A_1| \leq \frac{|\nu (\nu - 1)| \theta_+^2}{2 x^{2 \epsilon}} 1\{\theta_+ \leq x^\epsilon\}
\]

and therefore \( \mathbb{E}_x[A_1] = O(x^{2 \epsilon - 2}) = o(x^{-\alpha}) \), since \( \epsilon < \frac{2 - \alpha}{2} \).

We now show that

\[
\mathbb{E}_x[A_2] = \alpha x^{-\alpha} \int_0^\infty ((1 + u)^{\nu - 1} - 1) u^{-\alpha} du + o(x^{-\alpha});
\]

(4.6)
the integral here being finite by Lemma B.7 (with \( p = 1 - \alpha, q = \nu \)). To get (4.6), define
\[
g_x : \mathbb{R}_+ \rightarrow \mathbb{R} \text{ by } g_x(y) = (1 + y/x)^\nu - 1 - \nu y/x,
\]
which is differentiable with derivative
\[
g_x' (y) = (\nu/x)((1 + y/x)^{\nu-1} - 1).
\]
Since \( g_x'(y) > 0 \) for all \( y > 0 \) if \( \nu < 0 \) or \( \nu > 1 \), and \( g_x'(y) < 0 \) for all \( y > 0 \) if \( \nu \in (0,1) \), \( g_x \) is monotonic, and applying Lemma A.1 we obtain
\[
E_x [A_2] = g_x(x^\alpha) P_x[\theta_+ > x^\alpha] + \int_{x^\alpha}^\infty g_x'(y) P_x[\theta_+ > y] dy,
\]
the integral being finite for any \( x > x_0 \), since \( g_x' \) is continuous and finite over \([x^\alpha, \infty)\), and \( g_x'(y) = O(y^{\nu-1}) \) as \( y \to \infty \), so, by the \( \alpha \)-tail assumption in (T\(_{\alpha,\beta,\varepsilon}\)), the integrand decays like \( y^{\nu-\alpha-1} \). Another Taylor’s theorem calculation shows \( g_x(x^\alpha) = O(x^{2\nu-2}) = o(x^{-\alpha}) \).

We now consider the \( x \to \infty \) asymptotics of the integral in (4.7). First note that,
\[
\left| \int_{x^\alpha}^\infty g_x'(y) P_x[\theta_+ > y] dy - \int_{x^\alpha}^\infty g_x'(y) y^\alpha dy \right| \leq \int_{x^\alpha}^\infty |g_x'(y)| |y^\alpha P_x[\theta_+ > y] - c| y^{-\alpha} dy.
\]
Then by assumption (T\(_{\alpha,\beta,\varepsilon}\)), for any \( \delta > 0 \) we can find \( x_1 \in \mathbb{R}_+ \) such that, for all \( x \geq x_1 \),
\[
\int_{x^\alpha}^\infty |g_x'(y)| |y^\alpha P_x[\theta_+ > y] - c| y^{-\alpha} dy \leq \delta \int_{x^\alpha}^\infty |g_x'(y)| y^{-\alpha} dy \leq \delta \int_{0}^\infty |g_x'(y)| y^{-\alpha} dy,
\]
because \( g_x'(y) \) never changes sign. Also, by Taylor’s theorem again,
\[
\left| \int_{x^\alpha}^\infty g_x'(y) y^{-\alpha} dy \right| = \left| \int_{x^\alpha}^{x^\alpha + \varepsilon} g_x'(y) y^{-\alpha} dy \right| \leq C x^{-2} \int_{0}^\infty |\nu(\nu - 1)| y^{-\alpha} dy = o(x^{-\alpha})
\]
since \( \alpha < 2 \) and \( \varepsilon < 1 \). Therefore,
\[
\left| \int_{x^\alpha}^\infty g_x'(y) P_x[\theta_+ > y] dy - \int_{0}^\infty g_x'(y) y^\alpha dy \right| \leq \delta \int_{0}^\infty g_x'(y) y^{-\alpha} dy + o(x^{-\alpha}),
\]
and since \( \delta > 0 \) was arbitrary, we have
\[
\int_{x^\alpha}^\infty g_x'(y) P_x[\theta_+ > y] dy = (c + o(1)) \int_{0}^\infty g_x'(y) y^{-\alpha} dy + o(x^{-\alpha}),
\]
which, after the change of variable \( y = ux \), and using (4.7), yields (4.6).

Thus from the fact that \( E_x[f_0(x + \theta_+) - f_0(x)] = x^\nu E_x[A_1 + A_2 + A_3] \), we obtain
\[
E_x[f_0(x + \theta_+) - f_0(x)] = c\nu x^{\nu-\alpha} \int_{0}^\infty ((1 + u)^{\nu-1} - 1) u^{-\alpha} du + nx^{\nu-1} E_x[\theta_+] + o(x^{\nu-\alpha}).
\]

We now consider \( E_x[f_0(x - \theta_-) - f_0(x)] \) in (4.3). Fix (another) \( \varepsilon \in (0,1) \) with \( \varepsilon < \frac{\nu + \beta - \alpha}{2} \) and \( \varepsilon < \frac{\beta - \alpha}{2} \); this choice is possible since \( \alpha < \beta \) and \( \nu > \alpha - \beta \). Note that, for \( \nu < 0 \), the Lyapunov function satisfies \( f_0(x) \in [0,1] \) for all \( x \in \mathbb{R}_+ \), so that, for \( x > x_0 \),
\[
| E_x [(f_0(x - \theta_-) - f_0(x)) 1_{\{\theta_- > x^{1-\varepsilon}\}}] | \leq P_x[\theta_- > x^{1-\varepsilon}] \leq C x^{-\beta(1-\varepsilon)} = o(x^{-\alpha}),
\]
by Markov’s inequality, the \( \beta \)-moments assumption in (T\(_{\alpha,\beta,\varepsilon}\)), and the choice of \( \varepsilon \). On the other hand, if \( \nu > 0 \), then \( f_0 \) is non-decreasing and, for \( x > x_0 \),
\[
| E_x [(f_0(x - \theta_-) - f_0(x)) 1_{\{\theta_- > x^{1-\varepsilon}\}}] | \leq x^\nu P_x[\theta_- > x^{1-\varepsilon}] \leq C x^{1-\beta(1-\varepsilon)} = o(x^{\nu-\alpha}),
\]
again, by choice of \( \varepsilon \). It remains to consider the random variable
\[
(f_0(x - \theta_-) - f_0(x)) 1_{\{\theta_- \leq x^{1-\varepsilon}\}} = x^\nu ((1 - \theta_-/x)^\nu - 1) 1_{\{\theta_- \leq x^{1-\varepsilon}\}},
\]

EJP 24 (2019), paper 62. http://www.imstat.org/ejp/
Markov chains with heavy-tailed increments and asymptotically zero drift

for all \( x \) sufficiently large. Using (4.5) for \( z = -\theta_+/x \), we obtain

\[
(1 - \theta_+/x)^{\nu} + \nu \theta_+/x \lfloor \theta_+ \leq x^{1-\epsilon} \rfloor \leq \frac{[\nu(\nu-1)]\theta^2}{2x^2} (1 + O(x^{-\epsilon})) \lfloor \theta_+ \leq x^{1-\epsilon} \rfloor.
\]

Assumption (T\(_{\alpha,\beta,c}\)) means that there exists \( \beta' \in (0, 2) \) with \( \lim sup_{x \to \infty} E_x[\theta^\beta] < \infty \), so that \( E_x[\theta^\beta \lfloor \theta_+ \leq x^{1-\epsilon} \rfloor] \leq x^{(2-\beta')(1-\epsilon)} E_x[\theta^\beta] = o(x^{2-\alpha}) \), by choice of \( \beta' \). Therefore

\[
E_x[f_0(x - \theta_+) - f_0(x)] = -\nu x^{\nu-1} E_x[\lfloor \theta_+ \leq x^{1-\epsilon} \rfloor] + o(x^{\nu-\alpha}). \tag{4.10}
\]

Also, assumption (T\(_{\alpha,\beta,c}\)) yields \( E_x[\theta \lfloor \theta_+ > x^{1-\epsilon} \rfloor] \leq x^{(1-\beta)(1-\epsilon)} E_x[\theta^\beta] = o(x^{1-\alpha}) \), since \( \epsilon < \frac{\beta-\alpha}{\beta} < \frac{\beta-\alpha}{\beta-1} \). Thus combining (4.8) and (4.10), we get

\[
D_0(x) = \nu x^{\nu-1} E_x[\theta] + c \nu x^{\nu-\alpha} \int_0^\infty ((1+u)^{\nu-1} - 1) u^{-\alpha} du + o(x^{\nu-\alpha}).
\]

Finally, using Lemma B.7 with \( p = 1 - \alpha \) and \( q = \nu \), the integral \( \int_0^\infty ((1+u)^{\nu-1} - 1) u^{-\alpha} du \) is equal to \( (1-\nu)\Gamma(\alpha-\nu) \Gamma(1-\alpha)/\Gamma(2-\nu) \) and the result follows. \( \square \)

4.3 Lyapunov functions on the whole line

In the case of heavier outwards tails, the computations for \( f_1 \) and \( f_2 \) are naturally related to those that we did for \( f_0 \) in the last section, so we can reuse many calculations here.

**Lemma 4.3.** Suppose that the random walk \( \Xi \) on \( \mathbb{R} \) satisfies (T\(_{\alpha,\beta,c}^{\text{out}}\)). Then, for any \( \nu \) for which \( \alpha - \beta < \nu < \alpha \), the following hold. First, as \( x \to +\infty \),

\[
D_1(x) = \nu x^{\nu-1} E_x[\theta] + c \nu x^{\nu-\alpha} \kappa_0(\nu) + o(x^{\nu-\alpha}),
\]

where \( \kappa_0 \) is defined at (4.2). Second, as \( x \to \pm \infty \),

\[
D_2(x) = \nu \text{sgn}(x) |x|^{\nu-1} E_x[\theta] + c \nu |x|^{\nu-\alpha} \kappa_0(\nu) + o(|x|^{\nu-\alpha}). \tag{4.11}
\]

**Proof.** Suppose that \( x \geq 1 \). Here the relevant part of assumption (T\(_{\alpha,\beta,c}^{\text{out}}\)) coincides with the assumption (T\(_{\alpha,\beta,c}\)) used in the proof of Lemma 4.2. Moreover, since \( f_0(x) = f_1(x) = f_2(x) \) for all \( x \geq 0 \) (and a fixed \( \nu \)), conditional on \( \xi_n = x \) it is clearly the case that \( f_i(x + \theta_+) \) and \( f_i(x - \theta+) \) do not depend on which \( i \in \{0, 1, 2\} \) we are using. Thus the only difference from our computation in Lemma 4.2 arises from the possibility now that \( \theta_+ > x \) (which was previously precluded).

In the places in the proof of Lemma 4.2 where \( \theta_+ \) is allowed to be big, we used only that (i) \( f_0(x) = 1 \) for \( x \leq 1 \), (ii) \( f_0(x) \in [0, 1] \) for all \( x \in \mathbb{R}_+ \) if \( \nu < 0 \), and (iii) \( f_0(x) \) is non-decreasing for \( x \in \mathbb{R}_+ \) if \( \nu > 0 \). All of (i)-(iii) extend to \( x \in \mathbb{R} \) with \( f_1 \) in place of \( f_0 \).

Thus the proof of the result for \( f_1 \) follows verbatim that of Lemma 4.2, replacing \( f_0 \) by \( f_1 \), and noting that some statements should be extended from \( \mathbb{R}_+ \) to \( \mathbb{R} \).

Consider \( f_2 \). Suppose that we can show that (4.11) holds for \( x \to +\infty \). If assumption (T\(_{\alpha,\beta,c}^{\text{out}}\)) holds for \( \xi_n \), it also holds for \( -\xi_n \). Then by the symmetry \( f_2(-x) \equiv f_2(x) \), we may apply (4.11) to the process \( -\xi_n \), to get that \( D_2(-x) = E[f_2(-\xi_{n+1}) - f_2(-\xi_n) | -\xi_n = x \] is, as \( x \to +\infty \), equal to the right-hand side of (4.11) but with \( E_x[\theta] \) replaced by \( -E_{-x}[\theta] \). This shows that (4.11) also holds for \( x \to -\infty \). Thus it suffices to prove (4.11) for \( x \to +\infty \); so we take \( x \geq 1 \), as in the first paragraph of this proof.

We describe how to modify the proof of Lemma 4.2 to obtain (4.11). For \( \nu = 1 \), the analogue of (4.4) is

\[
D_2(x) = E_x[\theta_+] - E_x[\theta \lfloor \theta_+ \leq x-1 \rfloor] + E_x[(1-x)\lfloor x-1 < \theta_+ \leq x+1 \rfloor] \\
+ E_x[(\theta_+ - 2x)\lfloor \theta_+ > x+1 \rfloor] = E_x[\theta] + E_x[(\theta_+ - (x-1))\lfloor \theta_+ > x-1 \rfloor] + E_x[(\theta_+ - (x+1))\lfloor \theta_+ > x+1 \rfloor].
\]
It follows that 0 ≤ D_2(x) - E_x[θ] ≤ 2E_x[θ I{θ > x - 1}], and so D_2(x) = E_x[θ] + o(x^{1-α}) as before.

Now suppose that α - β < ν < α with ν ∉ {0, 1}. Following the proof of Lemma 4.2 exactly, we can show that equation (4.8) holds for f_2 in place of f_0. Now consider E_x[f_2(x - θ - ) - f_2(x)]. The random variable (f_2(x - θ - ) - f_2(x))I{θ - ≤ x^{1-ε}} can be dealt with in exactly the same way as in the proof of Lemma 4.2, so to show that the analogue of equation (4.10) holds for f_2, it is enough to prove that, as x → +∞,

E_x[(f_2(x - θ - ) - f_2(x))I{θ - > x^{1-ε}}] = o(x^{ν-α}).  \tag{4.12}

If ν < 0 this follows in the same way as (4.9), since f_2(x) ∈ [0, 1] for all x ∈ R. If ν > 0, then f_2(x - θ - ) ≤ f_2(x) whenever θ - ≤ 2x, so we have

\[ |E_x[(f_2(x - θ - ) - f_2(x))I{x^{1-ε} < θ - ≤ 2x}]| ≤ x^{ν}P_x[θ - > x^{1-ε}] ≤ Cx^{ν-β(1-ε)} = o(x^{ν-α}), \]

for small enough ε > 0 because β > α. Since f_2(x - θ - ) - f_2(x) ≤ θ if θ > 2x, we have

\[ |E_x[(f_2(x - θ - ) - f_2(x))I{θ - > 2x}]| ≤ E_x[θ I{θ - > 2x}] ≤ Cx^{ν-β} = o(x^{ν-α}) \]

because β > α. This proves (4.12), and hence also the analogue of (4.10) for f_2. The remainder of the proof exactly follows the proof of Lemma 4.2.

Now we turn to the case of heavier inwards tails. Define

\[ \kappa_1(ν) := \kappa_1(β, ν) := -\frac{(1 - β + ν)Γ(ν + 1)Γ(1 - β)}{Γ(2 - β + ν)}, \text{ and} \]

\[ \kappa_2(ν) := \kappa_2(β, ν) := \frac{Γ(β - ν)}{Γ(β)} - \frac{(1 - β + ν)Γ(1 - β)}{Γ(2 - β + ν)}. \]

**Lemma 4.4.** Suppose that the random walk Ξ on R satisfies (T_{α,β,c}^i). Then, for any ν for which 0 < ν < β, the following hold. (i) As x → +∞,

\[ D_1(x) = ν x^{ν-1} E_x[θ] + c x^{ν-β} \kappa_1(ν) + o(x^{ν-β}). \]

(ii) As x → ±∞,

\[ D_2(x) = ν sgn(x)|x|^{ν-1} E_x[θ] + cν |x|^{ν-β} \kappa_2(ν) + o(|x|^{ν-β}). \]

If in addition, assumption (T_{α,β,c}^i) is satisfied for some δ > 0, then the asymptotic expression in (ii) also holds for -δ_* < ν < 0, where δ_* = min{δ, 1}.

**Proof.** As in the proof of Lemma 4.3, for both results it suffices to suppose that x ≥ 1 (and later to take x → +∞). Also, without loss of generality, we may suppose that 1 < β < α < 2. We can treat f_1 and f_2 together for most of the computations. Indeed, let i ∈ {1, 2}. Then, by the monotonicity of x → f_i(x) for x ≥ 1,

\[ E_x[|f_i(x + θ + ) - f_i(x)|I{θ + ≥ x}] ≤ \begin{cases} E_x[(2θ_+)^I{θ + ≥ x}] & \text{for } ν > 0, \\ x^{ν}P_x[θ + ≥ x] & \text{for } ν < 0. \end{cases} \]

Suppose that ν < β. Markov’s inequality with assumption (T_{α,β,c}^i) implies that, for x > x_0,

\[ P_x[θ + ≥ x] ≤ C x^{-α} = o(x^{-β}), \]

and since ν < β < α we also have

\[ E_x[θ_+^{ν}I{θ + ≥ x}] ≤ x^{ν-α} E_x[θ_+^{ν}I{θ + ≥ x}] ≤ C x^{ν-α} = o(x^{ν-β}). \]

EJP 24 (2019), paper 62. http://www.imstat.org/ejp/
Now consider $E_x[|f_i(x + \theta_+) - f_i(x) - \nu x^{\nu-1}\theta_+|1\{\theta_+ < x\}]$. Using (4.5), and the fact that $(T_{\alpha,\beta,c}^m)$ holds for some $\alpha \in (1, 2)$, we can bound this expression by

$$x^{\nu} E_x \left[ \frac{\mu(\nu - 1)|\theta_+|}{2\nu} 1\{\theta_+ < x\} \right] \leq C x^{\nu-\alpha} E_x[\theta_+^\alpha 1\{\theta_+ < x\}] = o(x^{\nu-\beta}).$$

Since $x^{\nu-1} E_x[\theta_+ 1\{\theta_+ \geq x\}] \leq C x^{\nu-1} \cdot C x^{1-\alpha} = o(x^{\nu-\beta})$, these results combine to give

$$E_x[f_i(x + \theta_+) - f_i(x)] = C x^{\nu-1} E_x[\theta_+] + o(x^{\nu-\beta}). \quad (4.15)$$

For the expectation $E_x[f_i(x - \theta_-) - f_i(x)]$, we consider the random variables

$$B_{i,1} = (f_i(x - \theta_-) - f_i(x) + \nu x^{\nu-1}\theta_-) 1\{\theta_- \leq x^{\epsilon}\},
B_{i,2} = (f_i(x - \theta_-) - f_i(x) + \nu x^{\nu-1}\theta_-) 1\{\theta_- > x^{\epsilon}\},
B_{i,3} = -\nu x^{\nu-1}\theta_-,$$

where $\epsilon \in (0, \frac{2-\beta}{2})$ is fixed. For $x \geq 1$ we can write

$$|B_{i,1}| = x^{\nu}[(1 - \theta_-/x)^\nu - 1 + \nu\theta_-/x] 1\{\theta_- \leq x^{\epsilon}\},$$

and using (4.5) with $z = -\theta_-/x$ (valid since $\nu < \beta < 2$ and $-\theta_-/x \geq -x^{\epsilon-1} > -1$ for large enough $x$), we find that for $i \in \{1, 2\}$, for all large enough $x$,

$$|B_{i,1}| \leq \frac{1}{2} x^{\nu-2} \mu(\nu - 1) \theta_-^2 (1 - \theta_-/x)^{\nu-2} 1\{\theta_- \leq x^{\epsilon}\} \leq |\nu(\nu - 1)| x^{\nu+2\epsilon-2},$$

and therefore $E_x[B_{i,1}] = o(x^{\nu-\beta})$ by choice of $\epsilon$.

It is in the calculation of $E_x[B_{i,2}]$ that we see the difference between the $f_i$. Define the function $h_{i,x} : R_+ \rightarrow R$ by $h_{i,x}(y) = f_i(x - y) - f_i(x) + \nu x^{\nu-1}y$, which, as a function of $y$, is continuous on $R_+$ and only fails to be differentiable at $y = x - 1$ and in the case of $i = 2$, also at $y = x + 1$. Away from these two points, the derivative is

$$h'_{i,x}(y) = \begin{cases} -\nu(x-y)^{\nu-1} + \nu x^{\nu-1} & \text{for } 0 < y < x - 1, \\
\nu x^{\nu-1} & \text{for } x - 1 < y < x + 1, \\
(i-1)\nu(y-x)^{\nu-1} + \nu x^{\nu-1} & \text{for } y > x + 1. \end{cases} \quad (4.16)$$

Hence $h_{i,x}$ is piecewise monotonic, and we can apply Lemma A.1 to get

$$E_x[B_{i,2}] = h_{i,x}(x^\gamma) \mathbb{P}_x[\theta_- > x^\gamma] + \int_{x^\gamma}^{\infty} h'_{i,x}(y) \mathbb{P}_x[\theta_- > y]dy, \quad (4.17)$$

and the integral is finite for fixed $x > x_0$, since as $y \rightarrow \infty$ the integrand decays like $y^{-\beta}$ (if $i = 1$, or $i = 2$ and $\nu \leq 1$) or $y^{\nu-1}$ (if $i = 2$ and $\nu > 1$). Using (4.5) we find that $h_{i,x}(x^\gamma) = O(x^{\nu+2\epsilon-2}) = o(x^{\nu-\beta})$.

Consider the integral in (4.17). Let $\delta(y) = \sup_{x \geq x_0} \sup_{y \geq y} |z\mathbb{P}_x[\theta_- > z] - c|$; then $\delta(y)$ is non-increasing and, by assumption $(T_{\alpha,\beta,c}^m)$, $\delta(y) \rightarrow 0$ as $y \rightarrow \infty$. From (4.16), using Taylor’s theorem and the fact that $\beta < 2$, for any $\gamma \in (0, 1)$ we obtain

$$\left| \int_0^{x^\gamma} h'_{i,x}(y) y^{-\beta}dy \right| = \int_0^{x^\gamma} |h'_{i,x}(y)| y^{-\beta}dy \leq 2 x^{\nu-2} |\nu(\nu - 1)| \int_0^{x^\gamma} y^{-\beta}dy = o(x^{\nu-\beta}),$$

for $x$ large enough that $x^\gamma < x - 1$ holds, and a similar bound holds with $\mathbb{P}_x[\theta_- > y]$ in place of $y^{-\beta}$, provided that in addition $x > x_0$. Hence, for any $k \in (\epsilon, 1)$,

$$\left| \int_{x}^{\infty} h'_{i,x}(y) \mathbb{P}_x[\theta_- > y]dy - \int_{0}^{\infty} h'_{i,x}(y)c y^{-\beta}dy \right| \leq \int_{x}^{\infty} h'_{i,x}(y) \mathbb{P}_x[\theta_- > y]dy - \int_{x}^{\infty} h'_{i,x}(y)c y^{-\beta}dy + o(x^{\nu-\beta}).$$
Markov chains with heavy-tailed increments and asymptotically zero drift

By (4.16), the sign of $h'_{i,x}(y)$ is constant on $(0, x - 1)$ and on $(x - 1, \infty) \setminus \{x + 1\}$: thus

$$\left| \int_{x^{-}}^{\infty} h'_{i,x}(y) \mathbb{P}_x[\theta_+ > y] \, dy - \int_{x^{-}}^{\infty} h'_{i,x}(y) cy^{-\beta} \, dy \right| \leq \delta(x^\kappa) \left( \left| \int_{x^{-}}^{\infty} h'_{i,x}(y) y^{-\beta} \, dy \right| + \left| \int_{x^{-}}^{\infty} h'_{i,x}(y) y^{-\beta} \, dy \right| \right).$$

Therefore, for $\kappa \in (\varepsilon, 1)$, as $x \to +\infty$,

$$\left| \int_{x^{-}}^{\infty} h'_{i,x}(y) \mathbb{P}_x[\theta_+ > y] \, dy - \int_{0}^{\infty} h'_{i,x}(y) cy^{-\beta} \, dy \right| \leq \delta(x^\kappa) \left( \left| \int_{0}^{x-1} h'_{i,x}(y) y^{-\beta} \, dy \right| + \left| \int_{x-1}^{\infty} h'_{i,x}(y) y^{-\beta} \, dy \right| \right) + o(x^{\nu-\beta}). \tag{4.18}$$

For both $i \in \{1, 2\}$, we get from (4.16) that for $\nu > -1$, $\nu \neq 0$,

$$\left| \int_{0}^{x-1} h'_{i,x}(y) y^{-\beta} \, dy \right| = \left| \nu x^{\nu-\beta} \int_{0}^{1-x^{-1}} ((1-u)^{\nu-1} - 1) u^{-\beta} \, du \right| \leq C x^{\nu-\beta} (1 + x^{-\nu}),$$

by an application of Corollary B.5 with $p = 1 - \beta$ and $q = \nu$. For $i = 2$, Lemma B.6 (with $p = 1 - \beta$, $q = \nu$) shows that for $-1 < \nu < \beta$, $\nu \neq 0$,

$$\left| \int_{x+1}^{\infty} h'_{2,x}(y) y^{-\beta} \, dy \right| = \left| \nu x^{\nu-\beta} \int_{1+x^{-1}}^{\infty} ((u-1)^{\nu-1} + 1) u^{-\beta} \, du \right| \leq C x^{\nu-\beta} (1 + x^{-\nu}).$$

More straightforward is the case $i = 1$, where we have

$$\left| \int_{x+1}^{\infty} h'_{1,x}(y) y^{-\beta} \, dy \right| = \left| \nu x^{\nu-1} \int_{x+1}^{\infty} y^{-\beta} \, dy \right| \leq C x^{\nu\nu-\beta}.$$

Trivially,

$$\left| \int_{x^{-1}}^{x+1} h'_{1,x}(y) y^{-\beta} \, dy \right| \leq 2 |\nu| x^{\nu-1} (x - 1)^{-\beta} \leq C x^{\nu\nu-\beta-1}.$$

Thus from (4.18) we obtain, for $i \in \{1, 2\}$,

$$\left| \int_{x^{-}}^{\infty} h'_{i,x}(y) \mathbb{P}_x[\theta_+ > y] \, dy - \int_{x^{-}}^{\infty} h'_{i,x}(y) cy^{-\beta} \, dy \right| \leq C (1 + x^{-\nu}) \delta(x^\kappa) x^{\nu\nu-\beta} + o(x^{\nu\nu-\beta}).$$

This last bound is $o(x^{\nu\nu-\beta})$ if either (i) $\nu > 0$, or (ii) $\delta(y) = O(y^{-\beta})$ for some $\delta > 0$, and $-\kappa \delta < \nu < 0$; taking $\kappa < 1$ close to 1, we can permit any $\nu > -\delta$. Thus, in either case, from (4.17) with (4.16) we have that $E_{x,B_{i,2}}$ is equal to $C x^{\nu\nu-\beta}$ times

$$\int_{0}^{1-x^{-1}} ((1-u)^{\nu-1} - 1) u^{-\beta} \, du + \int_{1-x^{-1}}^{\infty} u^{-\beta} \, du + (i-1) \int_{1-x^{-1}}^{\infty} (u-1)^{\nu-1} u^{-\beta} \, du + o(1).$$

A final application of Corollary B.5 and Lemma B.6 (with $p = 1 - \beta$ and $q = \nu$) yields expressions for $E_{x,B_{i,2}}$ which, when combined with (4.15) and the fact that $E_{x,B_{i,2}} = E_{x,B_{i,2}} - \nu x^{\nu-\beta} E_{x,\theta_+} + o(x^{\nu-\beta})$, give the claimed results. \qed

Finally, we state an analogous result in the case of balanced tails. The proof amounts to combining elements of the proofs of Lemmas 4.3 and 4.4, and is omitted.

**Lemma 4.5.** Suppose that the random walk $\Xi$ on $\mathbb{R}$ satisfies $(\text{T}_{\alpha,\varepsilon}^{\text{bal}})$. Then, for any $\nu$ for which $0 < \nu < \alpha$, the following hold. (i) As $x \to +\infty$,

$$D_1(x) = \nu x^{\nu-1} E_x[\theta] + c x^{\nu-\alpha}(\nu \kappa_0(\alpha, \nu) + \kappa_1(\alpha, \nu)) + o(x^{\nu-\alpha}).$$
(ii) As $x \to \pm \infty$,
\[
D_2(x) = \nu \operatorname{sgn}(x)|x|^{\nu-1}E_x[\theta] + c\nu|x|^\nu(\alpha, \nu) + \kappa_2(\alpha, \nu)) + o(|x|^{\nu-\alpha}).
\]

If in addition, the limit assumptions in (T_{\alpha,\beta,c}^+) are strengthened to $O(y^{-\delta})$ for some $\delta > 0$, then (ii) also holds for $-\delta_* < \nu < 0$, where $\delta_* = \min\{\delta, 1\}$.

5 Proofs of main results

5.1 The half line

First we establish our recurrence criteria.

Proof of Theorem 2.1. Under the conditions of part (i) of the theorem, Lemma 4.2 gives
\[
D_0(x) = \nu x^{\nu-\alpha} \left(x^{\alpha-1} \mu(x) + c\nu(\nu) + o(1)\right), \quad \text{for } \nu \in (\alpha - \beta, \alpha),
\]
where $\kappa_0$ is given at (4.2). If (2.1) holds, then there are $\varepsilon > 0$ and $x_1 \in \mathbb{R}_+$ such that $x^{\alpha-1} \mu(x) + c\nu \operatorname{cosec}(\pi \alpha) < -2\varepsilon$ for all $x \geq x_1$. Since $\kappa_0(0) = \Gamma(\alpha)\Gamma(1 - \alpha) = \pi \operatorname{cosec}(\pi \alpha)$, we find $\nu > 0$ such that $c\nu(\nu) < c\nu \operatorname{cosec}(\pi \alpha) + \varepsilon$. Then $x^{\alpha-1} \mu(x) + c\nu(\nu) \leq -\varepsilon$ for all $x \geq x_1$, so that the right-hand side of (5.1) is negative for all $x$ sufficiently large. Since $\nu > 0$, $f_0(x) \to \infty$ as $x \to \infty$, and Lemma 3.1 implies recurrence, noting (N).

Similarly, if (2.2) holds then we can find $\nu < 0$ such that the right-hand side of (5.1) is again negative for all $x$ sufficiently large, but now with $f_0(x) \to 0$ as $x \to \infty$. Hence Lemma 3.2 implies transience, again noting (N).

Finally, consider part (ii) of the theorem. Fix $\nu = \max\{1 + \gamma, 1\}$; since $\gamma < \alpha - 1$, we have $1 \leq \nu < \alpha$. Then Lemma 4.1 shows that, for any $\varepsilon > 0$,
\[
D_0(x) = \nu x^{\nu-1-\gamma} \left(x^\gamma \mu(x) + O(x^{1+\gamma-\alpha+\varepsilon})\right).
\]
Taking $\varepsilon > 0$ small enough and using the fact that $x^{\gamma} \mu(x) \leq -\delta$ for some $\delta > 0$ and all $x$ sufficiently large, we get $D_0(x) \leq -\delta \nu + o(1)$, and so Foster’s criterion (see e.g. Theorem 2.6.2 of [12]) yields positive recurrence.

Before proving Theorem 2.3 on moments of passage times, we state a lemma that we will need for our non-existence-of-moments results in the case where the drift is dominant.

Lemma 5.1. Suppose that (T_{\alpha,\beta,c}^+) holds, and $\liminf_{x \to \infty} x^{\gamma}(\mu(x)) > -\infty$ for some $\gamma$ with $0 \leq \gamma < \alpha - 1$. Then, for any $q \geq \frac{\alpha}{1 + \gamma}$, all $a$ large enough, and all $x > a$, $E_x[x^n] = \infty$.

Proof. Suppose that $x \geq x_0$. The idea is that the chain may start with a very big jump, and then takes a long time to return to near 0 (a similar idea was used in e.g. the proof of Theorem 2.10 of [7]). Fix $\eta = 1 + \gamma$, and for $x, y \in \mathbb{R}_+$ let $w_y(x) = (y - x)^\eta 1\{x < y\}$. We claim that there exist $y_0 \in \mathbb{R}_+$ and $B < \infty$ (not depending on $y$) such that
\[
E[w_y(\xi_{n+1}) - w_y(\xi_n) | \xi_n = x] \leq B, \quad \text{for all } y \geq y_0 \text{ and all } x \geq y/2.
\]
Given the claim, it follows from the maximal inequality in Theorem 2.4.7 of [12] that
\[
P\left[\min_{0 \leq m \leq n} \xi_m < y/2 \mid \xi_0 > y\right] \leq P\left[\max_{0 \leq m \leq n} w_y(\xi_m) \geq (y/2)^\eta \mid \xi_0 > y\right] \leq 4Bny^{-\eta},
\]
for all $y \geq y_0$ and all $n \geq 1$. Let $a \geq x_0$. Then for $x > a$ and any $A \in (0, \infty)$,
\[
P_x[\tau_n > n] \geq E_x\left[1\{\xi_1 > An^{1/\eta}\}P[\tau_n > n \mid \xi_1 > An^{1/\eta}]\right].
\]
Choosing $y = An^{1/\eta} > 2a$ in (5.3) for $A$ sufficiently large, we get, for all $n \geq 1$,

$$\mathbb{P}[\tau_n > n \mid \xi_1 > An^{1/\eta}] \geq 1 - 4BA^{-\eta} \geq 1/2. \quad (5.5)$$

Combining (5.4) and (5.5) and using (T, \theta, c), we get $\mathbb{P}_x[\tau_n > n] \geq c' n^{-\alpha/n}$ for some $c' > 0$ and all $n$ large enough, uniformly in $x > a \geq x_0$. Since $\eta = 1 + \gamma$, we get $E_x[\tau_n^\eta] = \infty$ for $x > a$ and $q > 1/\eta$.

It remains to prove (5.2). Under assumption (T, \theta, c), we have $\sup_{x > x_0} E_x[|\theta|^q] < \infty$ for any $q < \alpha$, so in particular this is true for $q = \eta$. Since $x \mapsto w_p(x)$ is non-increasing, if $y \geq y_0 \geq 2x_0$, say. By Taylor’s theorem, for some $C < \infty$, $|(1 - z)^{-1} - 1 + \eta z| \leq Cz^2$ for all $|z| \leq 1/2$. Thus

$$|w_p(x + \theta) - w_p(x) + \eta(y - x)^{n-1}\theta| \leq C\theta^2(y - x)^{n-2} \leq C\theta^2(y - x)^{n-2}1\{\theta < \frac{-y}{\eta}\},$$

so that, since $\theta^2 = |\theta|^2 \eta^{-\eta} \leq C(y - x)^{2-\eta}|\theta|^\eta$ on the event $\{|\theta| < \frac{-y}{\eta}\}$, we have

$$E_x[|w_p(x + \theta) - w_p(x) + \eta(y - x)^{n-1}\theta|1\{|\theta| < \frac{-y}{\eta}\}] = O(1).$$

Also $E_x[|\theta|^\eta1\{|\theta| < \frac{-y}{\eta}\}] \leq C(y - x)^{1-\eta}$. Putting these pieces together we get

$$E_x[w_p(x + \theta) - w_p(x)] \leq C - \eta(y - x)^{n-1} E_x[\theta] \leq B,$$

by choice of $\eta$ and the assumption on $\mu(x)$. This completes the proof of (5.2).\qed

**Proof of Theorem 2.3.** We first prove part (ii) of the theorem. Assuming that $x^{\alpha-1} \mu(x) = b + o(1)$, with $\kappa_0$ given by (4.2) we get from (5.1) that $D_0(x) = \nu x^{\nu-\alpha}(b + \kappa_0(\nu) + o(1))$. Recall that $\frac{d}{d\nu} \log \Gamma(z) = \psi(z)$ is the digamma function, which is strictly increasing on $z > 0$. For $\nu \leq \alpha$, we have

$$\frac{d}{d\nu} \kappa_0(\nu) = \frac{\Gamma(1-\alpha) \Gamma(\alpha - \nu)}{\Gamma(2-\nu)}((1 - \nu)(\psi(2 - \nu) - \psi(\alpha - \nu)) - 1).$$

For $\nu < \alpha \in (1, 2)$ we have $\Gamma(1 - \alpha) < 0$, $\Gamma(2 - \nu) > 0$, and $\Gamma(1 - \nu) > 0$, and since $\psi(\alpha - \nu) < \psi(2 - \nu)$, we have $\kappa_0(\nu) > 0$ for $\nu < 1$. For $\nu < 1$, using $\psi(2 - \nu) = \psi(1 - \nu) + \frac{1}{1 - \nu}$ and $\psi(1 - \nu) < \psi(\alpha - \nu)$, we also get $\kappa_0(\nu) > 0$ for $\nu < 1$. Thus $\kappa_0$ is strictly increasing on $[0, \alpha)$, with $\kappa_0(0) = \nu \psi(1 - \nu) + c\kappa(\nu) < 0$ and $\kappa_0(\nu) \to +\infty$ as $\nu \to \alpha$.

Hence if $b + \nu \psi(1 - \nu) + c\kappa(\nu) = 0$ there exists a unique $\nu^* \in (0, \alpha)$ such that $\kappa_0(\nu^*) = -b$, i.e., solving (2.3), such that the following two statements hold.

(a) For all $\nu \in (0, \nu^*)$ there exist $\delta > 0, x_1 \in \mathbb{R}_+$ so that $D_0(x) \leq -\delta x^{\nu-\alpha}$ for all $x \geq x_1$.

(b) For all $\nu \in (\nu^*, \alpha)$ there exist $\delta > 0, x_1 \in \mathbb{R}_+$ so that $D_0(x) \geq \delta x^{\nu-\alpha}$ for all $x \geq x_1$.

Since $f_0(x) = x^{\nu}$ for $x > 1$, we can rewrite the inequality in (a) as $D_0(x) \leq -\delta x^{1-(\alpha/\nu)}$, so (a) implies that for any $\kappa < 1 - (\alpha/\nu^*)$ we can choose $\nu$ less than but arbitrarily close to $\nu^*$ so that (3.1) holds for the process $Y_n = f_0(\xi_n)$. Therefore, for all $q < \nu^*/\alpha$, Lemma 3.9 shows that $E_x[\tau_n^\eta] < \infty$ for all $x > x_1$, the constant given in (a), and any $x$. 

EJP 24 (2019), paper 62. 
http://www.imstat.org/ejp/
Markov chains with heavy-tailed increments and asymptotically zero drift

On the other hand, since \( D_0(x) = O(x^{\nu-\alpha}) = o(1) \) for any \( \nu \in (0, \alpha) \), the process \( Y_n = f_0(\xi_n) \) satisfies (3.2). For \( r \in (1, \alpha/\nu) \), we note that
\[
E[(f_0(\xi_{n+1}))^r - (f_0(\xi_n))^r \mid \xi_n = x] = D_0^{\nu r}(x) = O(x^{\nu r-\alpha}). \tag{5.6}
\]
Since this is \( O((f_0(x))^{r-(\alpha/\nu)}) \), we see that (3.3) also holds. Similarly, taking \( r = p \) in (5.6) and using statement (b), we see that inequality (3.4) holds for any \( p \in (\nu r, \nu/\nu) \). Taking \( \nu \) less than but arbitrarily close to \( \alpha \) and applying Lemma 3.10 we obtain, for all \( q > \nu r/\alpha \), all \( \alpha \) sufficiently large, and all \( x > a_{\alpha} \), that \( E_x[\tau_y^2] = \infty \).

Next consider part (i). In this case \( x^{\alpha-1} \mu(x) \to 0 \), so we may apply part (ii) with \( b = 0 \). Clearly, the right hand side of (2.3) equals zero when \( \nu^* = 1 \), so this is (the unique) solution for \( b = 0 \), which yields the critical exponent \( 1/\alpha \), giving part (i).

Finally, consider part (iii). Here, we get from (5.1) that \( D_0(x) = \nu x^{\nu r-\gamma-1}(b + o(1)) \), where \( x^{\nu r-\gamma-1} = f_0(x)^{1-(\gamma+1)/\nu} \) for \( x \geq 1 \). So, for \( \nu < 0 \) and any \( \kappa < -1/\nu \), we can choose \( \nu \) less than but arbitrarily close to \( \alpha \) so that (3.1) holds for the process \( Y_n = f_0(\xi_n) \). Then Lemma 3.9 implies that \( E_x[\tau_y^2] < \infty \) for all \( q < \kappa^{-1} \). For the non-existence-of-moments result, we apply Lemma 5.1 (note that we cannot use Lemma 3.10, since here \( Y_n \) is never a submartingale).

\[ \square \]

5.2 The whole line

First we deal with the case of heavier outwards tails. Recall the definition of \( \kappa_0 \) at (4.2).

**Proof of Theorem 2.5.** Lemma 4.3 with assumptions \( (T_{out}^{\alpha,\beta,c}) \) and \( (D_{\gamma,b}^\prime) \) shows that
\[
D_1(x) = \nu ((b + o(1)) x^{\nu r-\gamma-1} + c + o(1)) x^{\nu r-\alpha} \kappa_0(\nu), \quad \text{as } x \to +\infty, \tag{5.7}
\]
\[
D_2(x) = \nu ((b + o(1)) |x|^{\nu r-\gamma-1} + c + o(1)) |x|^{\nu r-\alpha} \kappa_0(\nu), \quad \text{as } x \to -\infty. \tag{5.8}
\]

Lemma 4.3 with the symmetries of assumptions \( (T_{out}^{\alpha,\beta,c}) \) and \( (D_{\gamma,b}^\prime) \) also gives
\[
D_1'(x) := E[f_1(-\xi_{n+1}) - f_1(-\xi_n) \mid -\xi_n = x] = \nu ((b + o(1)) x^{\nu r-\gamma-1} + c + o(1)) x^{\nu r-\alpha} \kappa_0(\nu), \quad \text{as } x \to +\infty. \tag{5.9}
\]

Suppose that \( \gamma = \alpha - 1 \). Similarly to the proof of Theorem 2.1, if \( b + \pi \nu \csc(\pi \kappa) > 0 \), then, since \( \kappa_0(0) = \pi \csc(\pi \alpha) \), we can find \( \nu < 0 \) such that \( \nu(b + \nu c_0(\nu)) < 0 \), so that \( D_1(x) < 0 \) and \( D_1'(x) < 0 \) for all \( x \) sufficiently large. Lemma 3.5 with function \( f_1 \) then implies directional transience, giving part (v) of the theorem. If \( b + \pi \nu \csc(\pi \kappa) < 0 \), then we can find \( \nu > 0 \) such that \( \nu(b + \nu c_0(\nu)) > 0 \) again, so, by (5.8), \( D_2(x) < 0 \) for all \( |x| \) sufficiently large, and then Lemma 3.3 with function \( f_2 \) implies recurrence. The latter case also includes \( b = 0 \), so we get the recurrence in both parts (i) and (iv) of the theorem. The null recurrence follows from Theorem 2.6, which we establish below.

Finally, if \( \gamma < \alpha - 1 \) then for all \( x \) sufficiently large, \( D_1(x) \) and \( D_1'(x) \) have the same sign as \( \nu b \). For \( b > 0 \) we can choose \( \nu < 0 \) such that Lemma 3.5 with function \( f_1 \) implies directional transience. For \( b < 0 \), we can take \( \nu = 1 + \gamma \in (0, \alpha) \) to see by (5.8) that \( D_2(x) \leq -\varepsilon \) for all \( x \) outside of a bounded set, so Foster’s criterion (e.g. Theorem 2.6.2 of [12]) gives positive recurrence. This proves parts (ii) and (iii) of the theorem. \[ \square \]

**Proof of Theorem 2.6.** Suppose first that \( \gamma = \alpha - 1 \). Then we have from (5.8) that \( D_2(x) = \nu |x|^{\nu r-\alpha}(b + \nu c_0(\nu) + o(1)) \). This is the same asymptotics as for \( D_0(x) \) in the proof of Theorem 2.3, and we can follow that proof with \( Y_n = f_2(\xi_n) \). Setting \( b = 0 \) also gives the case \( \gamma > \alpha - 1 \). In the case \( \gamma < \alpha - 1 \) and \( b < 0 \), Lemma 5.1 carries through for \( x > 0 \), and a symmetric argument works for \( x < 0 \). \[ \square \]
We turn to heavier inwards tails. Recall $\kappa_1$ and $\kappa_2$ from (4.13) and (4.14). Note that, although the right hand side of (4.14) is undefined at $\nu = 0$, we have $\kappa_2(0+) = \kappa_2(0-)\) (see the proof of Theorem 2.7, below), so that we can extend $\kappa_2$ to a continuous function on $(-1, \beta)$.

**Proof of Theorem 2.7.** Now we have from Lemma 4.4 that

$$D_1(x) = (\nu(b + o(1))x^{\nu - \gamma} + (c + o(1))x^{\nu - \beta}\kappa_1(\nu)), \text{ as } x \to +\infty,$$
$$D_2(x) = \nu \left( (b + o(1))x^{\nu - \gamma} + (c + o(1))x^{\nu - \beta}\kappa_2(\nu) \right), \text{ as } x \to \pm \infty,$$
$$D'_1(x) = (\nu(b + o(1))x^{\nu - \gamma} + (c + o(1))x^{\nu - \beta}\kappa_1(\nu)), \text{ as } x \to +\infty,$$

where $D'_1$ is as defined at (5.9). Suppose first that $\gamma = \beta - 1$. Then $D_2(x) = \nu|x|^{\nu - \beta}(b + c\kappa_2(\nu) + o(1))$. Using the fact that $\Gamma(\nu) \sim 1/\nu$ and $\Gamma(z + \nu)/\Gamma(z) = 1 + \nu \psi(z) + O(\nu^2)$ as $\nu \to 0$, we get $\kappa_2(\nu) = \psi(1 - \beta) - \psi(\beta) + O(\nu)$. Hence $\kappa_2(0+) = \kappa_2(0-) = \psi(1 - \beta) - \psi(\beta) = \pi \cot(\pi \beta)$. So if $b + c\pi \cot(\pi \beta) < 0$, then we can find $\nu > 0$ so that $D_2(x) < 0$ for all $|x|$ sufficiently large, and Lemma 3.3 implies recurrence. If $b + c\pi \cot(\pi \beta) > 0$, then we can find $\nu < 0$ so that again $D_2(x) < 0$ for all $|x|$ sufficiently large, and Lemma 3.4 implies transience (here we need $(T^n_\nu)$) to allow us to take $\nu < 0$ in Lemma 4.4. Moreover, $\kappa_1(\nu) = -1 + O(\nu)$, so that we can find $\nu > 0$ so that $D_1(x) < 0$ and $D'_1(x) < 0$ for all $x$ sufficiently large, and Lemma 3.6 shows that transience is oscillatory. This proves parts (iv) and (vi) of the theorem, up to showing null recurrence in part (iv), which is covered by Theorem 2.9.

Now suppose that $\gamma > \beta - 1$. When $\beta < 3/2$, we can simply apply part (vi) with $b = 0$, and the fact that $\cot(\pi \beta) > 0$ gives oscillatory transience. For $\beta > 3/2$ we can apply part (iv) to get null recurrence. Thus we verify parts (i) and (v) of the theorem.

Finally, suppose that $\gamma < \beta - 1$. Lemma 4.1 shows that $D_1(x) = \nu bx^{\nu - \gamma}(1 + o(1))$, for $\nu$ in an interval $(-\varepsilon, \alpha)$, and the same holds for $D'_1(x)$. If $b < 0$ we may take $\nu = 1 + \gamma < \alpha$ to get positive recurrence (e.g. Theorem 2.6.2 of [12]), establishing part (ii). If $b > 0$ we may take $\nu < 0$ to conclude directional transience by an application of Lemma 3.5 with function $f_1$, giving part (iii). \hfill $\square$

**Proof of Theorem 2.9.** Suppose first that $\gamma = \beta - 1$ and $b + c\pi \cot(\pi \beta) < 0$. Then $D_2(x) = \nu|x|^{\nu - \beta}(b + c\kappa_2(\nu) + o(1))$. The function $\kappa_2$ is continuous on $(-1, \beta)$ with $b + c\kappa_2(0) = b + c\pi \cot(\pi \beta) < 0$ and $\kappa_2(\nu) \to +\infty$ as $\nu \to \beta$, so the equation $b + c\kappa_2(\nu) = 0$ has at least one solution in $(0, \beta)$. Since $\kappa_2$ is continuous on $(0, \beta)$, analytic and non-constant on $(0, \beta)$, with $b + c\kappa_2(0) = 0$, the zeros of $b + c\kappa_2(\nu)$ can accumulate only at $\nu = \beta$, but this is ruled out since $\kappa_2(\nu) \to +\infty$ as $\nu \to \beta$. Thus there are finitely many $\nu \in (0, \beta)$ with $b + c\kappa_2(\nu) = 0$. Call the smallest one $\nu_*$ and the largest $\nu^*$.

To show that $\nu_* = \nu^*$, we adapt an idea from Lemma 11 in [11]. Given $0 < \nu_1 \leq \nu_2 < \beta$, by Jensen’s inequality, $E_{\nu}[(f^2_{\nu_1}(x + \theta))^{\nu_2/\nu_1}] \geq (E_{\nu}[f^2_{\nu_1}(x + \theta)])^{\nu_2/\nu_1}$, so that for $x \geq 1$,

$$f^2_{\nu_2}(x) + D^2_{\nu_2}(x) \geq (f^2_{\nu_1}(x) + D^2_{\nu_1}(x))^{\nu_2/\nu_1} = \left| |x|^{\nu_2} - 1 + |x|^{\nu_2}D^2_{\nu_1}(x) \right|^{\nu_2/\nu_1} = f^2_{\nu_2}(x) + \frac{\nu_2}{\nu_1} |x|^{\nu_2 - \nu_1}D^2_{\nu_1}(x) + o(|x|^{\nu_2 - \beta}),$$

using the fact that $D^2_{\nu_2}(x) = \nu|x|^{\nu_2 - \beta}(b + c\kappa_2(\nu) + o(1))$. Using this again and simplifying we obtain $\kappa_2(\nu_2) \geq \kappa_2(\nu_1) + o(1)$, i.e., $\kappa_2(\nu_2) \geq \kappa_2(\nu_1)$. Thus $\kappa_2$ is non-decreasing on $(0, \beta)$ and so $b + c\kappa_2(\nu) = 0$ for all $\nu_* \leq \nu \leq \nu^*$. Therefore we must have $\nu_* = \nu^*$.

Hence $b + c\kappa_2(\nu) < 0$ for $\nu \in (0, \nu^*)$ and $b + c\kappa_2(\nu) > 0$ for $\nu \in (\nu^*, \beta)$. The proof of part (ii) of the theorem now follows that of Theorem 2.3(ii), setting $Y_n = f_2(\xi_n)$. 

EJP 24 (2019), paper 62. Page 22/28
Markov chains with heavy-tailed increments and asymptotically zero drift

If $\gamma > \beta - 1$, we may apply the $b = 0$ case of part (ii), assuming $\beta > 3/2$ so that $\cot(\pi\beta) < 0$. We observe that $\kappa_2(2\beta - 3) = 0$, so $\nu^* = 2\beta - 3$. This gives part (i).

Finally, if $\gamma < \beta - 1$ and $b < 0$ we get from (5.8) that $D_2(x) = \nu|x|^{\nu-\gamma-1}(b + o(1))$ for $\nu \in (0, \beta)$, and following the argument in the proof of Theorem 2.3(iii) gives the existence-of-moments result. For the non-existence result, the argument for Lemma 5.1 works with minor modifications: the big jump being taken in the other direction. □

Finally, we turn to the balanced case. In essence, the results follow from the fact that the three leading order terms of $D_1$ and $D_2$ appearing in Lemma 4.5 are the obvious combination of the terms of $D_1$ and $D_2$ appearing in Lemmas 4.3 and 4.4: namely, a drift term (common to both Lemmas 4.3 and 4.4), an outwards-tail term (as in Lemma 4.3), and an inwards-tail term (as in Lemma 4.4 but with $\beta$ replaced by $a$).

Proof of Theorem 2.11. We give a sketch of the argument in the critical case where $\gamma = \alpha - 1$. For transience and recurrence, we use $f_2$ and get from Lemma 4.5 that the sign of $D_2(x)$ for $\nu \approx 0$ and large $|x|$ is determined by

$$b + c(\kappa_0(0) + \kappa_2(0)) = b + c\pi(\cosec(\pi\alpha) + \cot(\pi\alpha)) = b + c\pi\cot(\frac{\pi\alpha}{2}).$$

In the critical case transience is again oscillatory, since in $D_1(x)$ the key quantity is $\nu(b + c\kappa_0(0)) + \kappa_1(0)$ which is $-1 + O(\nu)$. We omit the details, as they are similar to the previous proofs. □

Proof of Theorem 2.12. We give a brief sketch of the argument; it is again similar to previous proofs. For the critical case $\gamma = \alpha - 1$ and $b + c\pi\cot(\frac{\pi\alpha}{2}) < 0$, we get from Lemma 4.5 that $D_2(x) = \nu|x|^{\nu-\alpha}(b + c(\kappa_0(\nu) + \kappa_2(\nu)) + o(1))$, and part (ii) follows in a similar fashion to previous proofs, in this case because $\kappa_0 + \kappa_2$ is increasing on $(0, \alpha)$, with $b + c(\kappa_0(0) + \kappa_2(0)) < 0$ and $\kappa_0(\nu) + \kappa_2(\nu) \to +\infty$ as $\nu \to \alpha$.

For $\gamma > \alpha - 1$ we apply the $b = 0$ case of part (ii) noting that $\kappa_0(\alpha - 1) + \kappa_2(\alpha - 1) = 0$, so $\nu^* = \alpha - 1$, which yields part (i).

Finally, for the case $\gamma < \alpha - 1$ and $b < 0$, part (iii) follows as in previous proofs, the argument for Lemma 5.1 also working in the balanced case. □

5.3 Example in the plane

Proof of Theorem 2.14. For $\nu \in R$ we define the Lyapunov function $g : \mathbb{R}^2 \to \mathbb{R}_+$ by

$$g(x) := \begin{cases} ||x||^\nu & \text{for } ||x|| \geq 1, \\ 1 & \text{for } ||x|| < 1. \end{cases}$$

Suppose throughout that $||x|| \geq 1$. Using assumption (A), we can write

$$E[g(\xi_{n+1}) - g(\xi_n) | \xi_n = x] = p^R E_x[g(x + u_x\theta^R) - g(x)] + p^T E_x[g(x + v_x\theta^T) - g(x)].$$

Considering first the case of a radial jump, since $x = ||x||u_x$, we have

$$E_x[g(x + u_x\theta^R) - g(x)] = E_x[||x|| + \theta^R]^\nu - ||x||^\nu].$$

In the same way that Lemma 4.3 follows from the assumptions (T_{out}^{\alpha,\beta,c}) and (D_{out}^{\alpha,\beta,b}) of Section 2.3, here assumptions (B), (C), and (D) imply that for any $\nu \in (\alpha - \beta, \alpha)$,

$$E_x[g(x + u_x\theta^R) - g(x)] = e^{C\nu||x||^{\nu-\alpha}}\kappa_0(\alpha, \nu) + o(||x||^{\nu-\alpha}), \text{ as } ||x|| \to \infty.$$

(Not that the process $||\xi_n||$ does not itself satisfy assumptions (T_{out}^{\alpha,\beta,c}) and (D_{out}^{\alpha,\beta,b}) of Section 2.3, as the law of its increments is not sufficiently uniform in $x$.)

EJP 24 (2019), paper 62. http://www.imstat.org/ejp/

Page 23/28
We turn to the transverse jumps. Let \( \varepsilon \in (0, 2 - \alpha) \). Since \( \|x + v_x \theta^T\|^2 = \|x\|^2 + \|\theta^T\|^2 \),
\[
|g(x + v_x \theta^T) - g(x)| \leq \|x\|^\alpha \left( 1 + \|x\|^{-2\alpha} |\theta^T|^2 \right)^{\|\theta^T\|^2 - 1} 1\{ |\theta^T|^2 \leq \|x\|^\varepsilon \},
\]
which is bounded by a constant times \( \|x\|^\varepsilon - 2 \) for all \( \|x\| \geq 1 \). Thus, by our choice of \( \varepsilon \),
\[
E_x[|g(x + v_x \theta^T) - g(x)| 1\{ |\theta^T|^2 \leq \|x\|^\varepsilon \}] = o(\|x\|^{\varepsilon - \alpha}).
\] (5.10)
The function \( g_x : \mathbb{R} \to \mathbb{R} \) defined by \( g_x(y) = (\|x\|^2 + y)^{\nu/2} - \|x\|^\nu \) is differentiable and monotone on \( \mathbb{R}_+ \) with \( g_x(x^2) = g(x + v_x y) - g(x) \), so Lemma A.1 implies that
\[
E_x[(g(x + v_x \theta^T) - g(x)) 1\{ |\theta^T|^2 > \|x\|^\varepsilon \}]
= g_x(\|x\|^\varepsilon) P_x[|\theta^T|^2 > \|x\|^\varepsilon] + \int_0^\infty \nu (\|x\|^\varepsilon + y)^{(\nu/2) - 1} P_x[|\theta^T|^2 > y] dy. 
\] (5.11)
Similarly to (5.10), we have \( g_x(\|x\|^\varepsilon) = o(\|x\|^{\varepsilon - \alpha}) \). For the above integral, assumption (E) and the substitution \( y = \|x\|^\varepsilon u \) shows that (5.11) equals
\[
c^T \nu \|x\|^{\varepsilon - \alpha} \int_0^\infty (1 + u)^{(\nu/2) - 1} u^{-\alpha/2} du + o(\|x\|^{\varepsilon - \alpha}),
\]
provided that \( \alpha \in (1, 2) \) and \( \nu < \alpha \) so that the latter integral is convergent. Using the substitution \( t = (1 + u)^{-1} \), and combining the result with (5.10), gives
\[
E_x[|g(x + v_x \theta^T) - g(x)|] = c^T \nu \|x\|^{\varepsilon - \alpha}(1 + o(1)) \int_0^1 t^{2\nu - 1} (1 - t)^{-\alpha/2} dt.
\]
Therefore, recalling the beta integral and the definition of \( \kappa_0 \) from (4.2), we obtain
\[
E[g(\xi_{n+1}) - g(\xi_n) | \xi_n = x] = \nu \|x\|^{\varepsilon - \alpha} \left( p^R c^R \kappa_0(\alpha, \nu) + p^T c^T \kappa_0(\alpha/2, \nu/2) + o(1) \right).
\]
We saw in the proof of Theorem 2.1 that \( \kappa_0(\alpha, 0) = \pi \csc(\pi \alpha) \), and using the fact that \( \csc(\alpha) = 2 \csc(2\alpha) \cos(\alpha) \), we get that the leading order coefficient is
\[
\nu \nu \csc(\pi \alpha) \left( p^R c^R + 2p^T c^T \cos\left(\frac{\pi \alpha}{2}\right) \right) + o(\nu), \quad \text{as } \nu \to 0.
\]
Since \( \csc(\pi \alpha) < 0 \) for \( \alpha \in (1, 2) \), if \( p^R c^R + 2p^T c^T \cos(\pi \alpha/2) > 0 \) then there exists a \( \nu > 0 \) for which \( E[g(\xi_{n+1}) - g(\xi_n) | \xi_n = x] \leq 0 \) for all large enough \( \|x\| \), and we get the recurrence in part (i) of the theorem by Lemma 3.1 applied to \( X_n = \|\xi_n\| \) with \( f(x) = f_0(x) \) (which tends to \( \infty \)). On the other hand, if \( p^R c^R + 2p^T c^T \cos(\pi \alpha/2) < 0 \), then there exists a \( \nu < 0 \) for which again \( E[g(\xi_{n+1}) - g(\xi_n) | \xi_n = x] \leq 0 \) for all \( \|x\| \) large enough, and we get the transience in part (ii) of the theorem by Lemma 3.2 applied to \( X_n = \|\xi_n\| \) with \( f(x) = f_0(x) \) (which now tends to 0).
Finally, existence and non-existence of moments in the recurrent case follow by a similar argument to that in the proof of Theorem 2.3 in Section 5.1: indeed, further analysis of \( \frac{d}{d\nu} \kappa_0(\alpha, \nu) \) shows that it is positive for \( \nu \in [0, \alpha) \) and \( \alpha \in (0, 1) \cup (1, 2) \), and therefore for any \( \alpha \in (1, 2) \) the functions \( \nu \mapsto \kappa_0(\alpha, \nu) \) and \( \nu \mapsto \kappa_0(\alpha/2, \nu/2) \) are continuously increasing on \( [0, \alpha) \). Then, the expression
\[
p^R c^R \kappa_0(\alpha, \nu) + p^T c^T \kappa_0(\alpha/2, \nu/2)
\]
is finite and continuously increasing in \( \nu \) on \( [0, \alpha) \), by assumption it is negative for \( \nu = 0 \), and it is clearly positive for \( \nu = 1 \). Hence there is a unique \( \nu^* \in (0, 1) \) that solves (2.5). Applying Lemmas 3.9 and 3.10, it is possible to show that \( E_x[\tau_0^q] < \infty \) for \( q < \nu^*/\alpha \), and \( E_x[\tau_0^q] = \infty \) for \( q > \nu^*/\alpha \). In particular, \( E_x[\tau_n] = \infty \) and \( \Xi \) is null recurrent.
Applying the partial integration formula to the middle term above, we obtain

$$E[g(X)1\{X > a\}] = g(a)P[X > a] + \int_a^\infty g'(x)P[X > x]dx,$$

where both sides converge or diverge simultaneously.

**Proof.** By assumption, for each $i = 0, \ldots, k - 1$, the function $g$ is continuous on $[a_i, a_{i+1}]$ and $E[g(X)1\{a_i < X \leq a_{i+1}\}]$ is finite and, using e.g. Theorem 2.9.3 of [6], is equal to

$$\int_{a_i}^{a_{i+1}} g(x) dF_X(x) = g(a_{i+1})F_X(a_{i+1}) - g(a_i)F_X(a_i) - \int_{a_i}^{a_{i+1}} F_X(x)g'(x)dx$$

$$= g(a_i)P[X > a_i] - g(a_{i+1})P[X > a_{i+1}] + \int_{a_i}^{a_{i+1}} g'(x)P[X > x]dx.$$

If $a < a_k$ then $a \in [a_j, a_{j+1})$ for some $j < k$, and similar reasoning gives

$$E[g(X)1\{a < X \leq a_{j+1}\}] = g(a)P[X > a] - g(a_{j+1})P[X > a_{j+1}] + \int_{a}^{a_{j+1}} g'(x)P[X > x]dx.$$

Consequently, the result follows if

$$E[g(X)1\{X > a_k\}] = g(a_k)P[X > a_k] + \int_a^{a_k} g'(x)P[X > x]dx$$

and both sides converge or diverge simultaneously. In other words, without loss of generality, we may assume that $a \geq a_k$.

Under this assumption, we may also assume that $g$ is non-negative and non-decreasing on $[a, \infty)$, by passing to $\pm(g(x) - g(a))$ as necessary, and therefore for all $b > a$,

$$E[g(X)1\{X > a\}] \geq E[g(X)1\{a < X \leq b\}] + g(b)P[X > b] \geq E[g(X)1\{a < X \leq b\}].$$

Applying the partial integration formula to the middle term above, we obtain

$$E[g(X)1\{X > a\}] \geq \int_a^b g'(x)P[X > x]dx + g(a)P[X > a] \geq E[g(X)1\{a < X \leq b\}].$$

and the result follows by taking the limit $b \to \infty$, since the right hand side tends to the (possibly infinite) limit $E[g(X)1\{X > a\}]$ by monotone convergence.

**B Some useful integrals**

Recall that the beta function $B(p, q)$ is given by

$$B(p, q) = \frac{\Gamma(p)\Gamma(q)}{\Gamma(p+q)} = B(q, p).$$

The incomplete beta function $B_x(p, q)$, defined for $0 \leq x \leq 1$ by the integral

$$B_x(p, q) := \int_0^x u^{p-1}(1-u)^{q-1}du,$$  \hspace{1cm} (B.1)
is usually only defined for \( p, q > 0 \), in which case \( B_1(p, q) = B(p, q) \). However, the integral in (B.1) is finite for any \( q \in \mathbb{R} \) provided that \( x < 1 \) and \( p > 0 \), so we extend the definition of \( B_x(p, q) \) to this full range of the parameters. Note that then

\[
\lim_{x \uparrow 1} B_x(p, q) = \begin{cases} 
B(p, q) & \text{if } q > 0, \\
\infty & \text{if } q \leq 0.
\end{cases} \tag{B.2}
\]

The following recurrence relation is well known, but since it is usually assumed that \( q > 0 \), we repeat the proof here.

**Lemma B.1.** For \( 0 \leq x < 1 \), \( p > 0 \), and \( q \in \mathbb{R} \),

\[
qB_x(p, q) = (p + q)B_x(p, q + 1) - x^p(1 - x)^q.
\]

**Proof.** Since \( p > 0 \), we can write \( B_x(p, q) = B_x(p, q + 1) + B_x(p + 1, q) \), where all three terms are finite. Evaluating \( qB_x(p + 1, q) \) using integration by parts, yields

\[
qB_x(p + 1, q) = -x^p(1 - x)^q + pB_x(p, q + 1),
\]

which when combined with the previous identity gives the result.

**Lemma B.2.** For \( 0 \leq x < 1 \), \( p > -1 \), and \( q \in \mathbb{R} \),

\[
p\int_0^x u^{p-1}((1 - u)^q - 1)du = (p + q)B_x(p + 1, q) + x^p((1 - x)^q - 1).
\]

Moreover, for \( p > -1 \), \( p \neq 0 \), and \( q > 0 \),

\[
\lim_{x \uparrow 1} \int_0^x u^{p-1}((1 - u)^q - 1)du = (p + q) \frac{\Gamma(p)\Gamma(q)}{\Gamma(p + q + 1)} - \frac{1}{p}. \tag{B.3}
\]

**Remark B.3.** The identity (B.3) is easily proved when \( p > 0 \) and \( q > 0 \) (direct evaluation with the beta integral) or when \( p > -1 \), \( p \neq 0 \) and \( q > 1 \) (integration by parts); however, the region \(-1 < p < 0 \) and \( 0 < q < 1 \) is not covered by either of these cases.

**Proof.** Let \( \phi(u) = u^{p-1}(1 - u)^q - 1 \). Taylor’s theorem around \( u = 0 \) gives an \( \varepsilon \in (0, x) \) such that \( |\phi(u)| \) is bounded by a constant times \( u^p \) for \( u \in [0, \varepsilon] \), while, as \( x < 1 \), \( |\phi(u)| \) is uniformly bounded for \( u \in [\varepsilon, x] \). Thus, since \( p > -1 \), the integral is finite. Integrating by parts, noting that \( \lim_{u \to 0} u^p((1 - u)^q - 1) = 0 \) since \( p > -1 \), we get

\[
p\int_0^x u^{p-1}((1 - u)^q - 1)du = x^p((1 - x)^q - 1) + (q - 1)B_x(p + 1, q - 1),
\]

and applying Lemma B.1 yields the claimed identity. When \( q > 0 \), by the first part of the lemma and (B.2), the integral \( \int_0^x q\phi(u)du \) converges as \( x \to 1 \) to a finite limit, which equals \( \frac{x^p}{p}B(p + 1, q) - 1/p \), and gives the claimed expression since \( p\Gamma(p) = \Gamma(p + 1) \).

**Lemma B.4.** For \( 0 \leq x < 1 \), \( p > -1 \), and \( q \in \mathbb{R} \),

\[
p(p - 1) \int_0^x u^{p-2}((1 - u)^q + qu - 1)du = (p + q)(p + q + 1)B_x(p + 1, q + 1) + x^{p-1}((1 - x)^q + (p + q)x) + (p - 1)qx - p.
\]

Moreover, for \( p > -1 \), \( p \notin \{0, 1\} \), and \( q < 0 \),

\[
\lim_{x \uparrow 1} \int_0^x u^{p-2}((1 - u)^q + qu - 1)du = (p + q)(p + q + 1) \frac{\Gamma(p - 1)\Gamma(q + 1)}{\Gamma(p + q + 2)} + \frac{q}{p} - \frac{1}{p - 1}. \tag{B.4}
\]
Markov chains with heavy-tailed increments and asymptotically zero drift

Proof. The integral in the first display is finite for \( x < 1 \) and \( p > -1 \), by a similar argument to that in the proof of the Lemma B.2, since the integrand behaves like \( u^p \) as \( u \to 0 \). Then, integrating by parts yields

\[
(p-1) \int_0^x u^{p-2}(1-u)^q + qu - 1)du = x^{p-1}((1-x)^q + qx - 1) + q \int_0^x u^{p-1}((1-u)^{q-1} - 1)du,
\]

and the required identity follows after applying Lemma B.2 and then Lemma B.1. When \( q > -1 \) and \( p \notin \{0, 1\} \), using the first part of the lemma and (B.2), the integral \( \int_0^x u^{p-2}((1-u)^q + qu - 1)du \) converges as \( x \to 1 \) to

\[
\frac{(p+q)(p+q+1)}{p(p-1)} B(p+1,q+1) + \frac{q}{p} \frac{1}{p-1}.
\]

and the result follows since \( p(p-1)\Gamma(p-1) = \Gamma(p+1) \).

We can now collect the statements that we will need in the body of the paper. The first, Corollary B.5, is for \( q > 0 \) no stronger than the identity (B.3) above, but for \( q \in (-1,0) \) it quantifies the rate of divergence of the integral as \( x \to \infty \).

**Corollary B.5.** Let \( p \leq -1 \), \( p \neq 0 \) and \( q > -1 \), \( q \neq 0 \). As \( x \to \infty \),

\[
\int_0^{1-x^{-1}} u^{p-1}((1-u)^{q-1} - 1)du = -\frac{x^{-q}}{q} + (p+q)(p+q+1) \frac{\Gamma(p)\Gamma(q)}{\Gamma(p+q+2)} - \frac{1}{p} + o(1).
\]

**Proof.** The case \( p = 1 \) follows by a direct evaluation of the integral. Otherwise, for any \( q \in \mathbb{R} \), and \( p > -1 \), \( p \notin \{0,1\} \), integration by parts yields

\[
-q \int_0^{1-x^{-1}} u^{p-1}((1-u)^{q-1} - 1)du = (1-x^{-1})^{p-1}(x^{-q} + q(1-x^{-1}) - 1)
\]

\[
- (p-1) \int_0^{1-x^{-1}} u^{p-2}((1-u)^q + qu - 1)du,
\]

which is valid for any \( x > 0 \), since \( p > -1 \). For \( q > -1 \),

\[
(1-x^{-1})^{p-1}(x^{-q} + q(1-x^{-1}) - 1) = x^{-q} + q - 1 + o(1),
\]

and the claimed identity follows from (B.4). \( \square \)

The remaining two results are more straightforward.

**Lemma B.6.** For \( p,q \in \mathbb{R} \) with \( q > -1 \), \( q \neq 0 \), and \( p + q < 1 \), as \( x \to \infty \),

\[
\int_{1+x^{-1}}^{\infty} u^{p-1}((u-1)^{q-1} du = -\frac{x^{-q}}{q} + (1-p) \frac{\Gamma(1-p-q)\Gamma(q)}{\Gamma(2-p)} + o(1).
\]

**Proof.** Integrating by parts, we find

\[
q \int_{1+x^{-1}}^{\infty} u^{p-1}((u-1)^{q-1} du = -(1+x^{-1})^{p-1}x^{-q} - (p-1) \int_{1+x^{-1}}^{\infty} u^{p-2}(u-1)^q du,
\]

which is valid for any \( x > 0 \), since \( p + q < 1 \). The change of variable \( v = u^{-1} \) yields

\[
\int_{1+x^{-1}}^{\infty} u^{p-2}(u-1)^q du = \int_0^{\frac{1}{x+1}} v^{-p-q}(1-v)^q dv = B(1-p-q,q+1) + o(1),
\]

by (B.2), provided \( q > -1 \). Now note that \( -(1+x^{-1})^{p-1}x^{-q} = -x^{-q} + o(1) \) for \( q > -1 \). \( \square \)
Lemma B.7. For $p, q \in \mathbb{R}$ with $-1 < p < 0$ and $p + q < 1$,
\[
\int_0^\infty u^{p-1}((1 + u)^{q-1} - 1)\,du = (1 - q)\frac{\Gamma(1 - p - q)\Gamma(p)}{\Gamma(2 - q)}.
\]
Proof. Integrating by parts, we find
\[
p\int_0^\infty u^{p-1}((1 + u)^{q-1} - 1)\,du = -(q - 1)\int_0^\infty u^p(1 + u)^{q-2}\,du,
\]
which is valid since $-1 < p < 0$ and $p + q < 1$. Setting $v = (1 + u)^{-1}$ yields
\[
\int_0^\infty u^p(1 + u)^{q-2}\,du = \int_0^1 v^{-p-q}(1 - v)^p\,dv = B(1 - p - q, p + 1),
\]
and the identity follows using the fact that $p\Gamma(p) = \Gamma(p + 1)$.
