Abstract

The resolvent convergence of self-adjoint operators via the technique of $\Gamma$-convergence of quadratic forms is adapted to incorporate complex Hilbert spaces. As an application, we find effective operators to the Dirichlet Laplacian with magnetic fields in very thin bounded tubular regions in space built along smooth closed curves; the convergence is in the norm resolvent sense as the cross sections of the tubes go uniformly to zero.

1 Introduction

Consider a family of (lower bounded) self-adjoint operators $T_\varepsilon$ ($\varepsilon > 0$) with domain $\text{dom } T_\varepsilon$ in a complex separable Hilbert space $H$, and the corresponding closed sesquilinear forms $b_\varepsilon$. We want to study the limit $T$ (resp. $b$) of $T_\varepsilon$ (resp. $b_\varepsilon$) as $\varepsilon \to 0$. We can relate this study to the concept of $\Gamma$-convergence; but when addressing sesquilinear forms these variational problems are usually formulated in real Hilbert spaces and the theory has been developed under this condition; see, for instance, some important monographs in the field as [3, 2]. However, in quantum mechanics the Hilbert spaces are usually complex, and here we have the first aim of this work, that is, to shortly explain the ideas involved in the $\Gamma$-convergence of quadratic forms and then describe the modifications needed to generalize the pertinent results to complex Hilbert spaces. It must be underlined that this adaptation to complex Hilbert spaces do not make things easier, but it is necessary to properly accommodate quantum mechanics, in particular if magnetic fields are present. As an application we study the effective operator obtained from the Dirichlet Laplacian with magnetic field restricted to closed bounded tubes in $\mathbb{R}^3$ that shrinks to a smooth curve. We emphasize that the presence of magnetic field doesn’t allow the restriction of this application to real Hilbert spaces; hence the importance of such generalization to complex Hilbert spaces.

There are several papers on the Dirichlet Laplacian without magnetic fields restricted to tubes in $\mathbb{R}^3$; see, for instance, [1, 8, 6, 7, 5]. In particular, the variational technique of $\Gamma$-convergence in real Hilbert spaces was invoked in [1, 5]. One of the first works in which a magnetic field was added to this kind of problem is the paper [10], where the author has obtained an asymptotic expansion of the eigenvalues; but special particularities about the field were imposed. In that work the problem was restricted to a sequence of bounded tubes $\Lambda_\varepsilon$ of the space that shrinks to a closed curve of $\mathbb{R}^2$ as $\varepsilon \to 0$. Recently, considering now that the tubes $\Lambda_\varepsilon$ are unbounded, it was proven...
in [12] the norm resolvent convergence under the condition that the vector field \( \mathbf{A} \) depends on a parameter, more precisely, it is of form \( b \mathbf{A} \) where \( b \) is positive and depends on \( \varepsilon \). Other variation of this problem was studied in [13], where the authors have considered the Dirichlet Laplacian between two parallel hypersurfaces in Euclidean space in the presence of a magnetic field. When the distance between them tends to zero, it was shown a norm resolvent convergence of the associated operators.

Let \( S \) be a circle of length \( l > 0 \) and \( r : S \to \mathbb{R}^3 \) a closed and simple curve of class \( C^3 \) in \( \mathbb{R}^3 \) parameterized by its arc length \( s \). Denote by \( k(s) \) and \( \tau(s) \) its curvature and torsion at the point \( r(s) \), respectively. Let \( Q \) be a smooth open, bounded, simply connected, and nonempty subset of \( \mathbb{R}^3 \). We build a tube \( \Omega \) in \( \mathbb{R}^3 \) by moving the region \( Q \) along \( r(s) \). At each point the region may present a rotation angle which is denoted by \( \alpha(s) \). Suppose that the functions \( k, (\tau + \alpha') \in L^\infty(S) \) and the Dirichlet condition at the boundary \( \partial\Omega \). We take a vector magnetic potential field \( \mathbf{A} = (A_1, A_2, A_3) \), where \( A_j : \Omega \to \mathbb{R}, j = 1, 2, 3, \) are real functions and we consider the family of operators

\[
(H_\varepsilon \psi)(x) := \left[ (-i\partial - \mathbf{A})^2 \psi \right](x) \quad (0 < \varepsilon < 1),
\]

\( \text{dom } H_\varepsilon = \mathcal{H}^2(\Omega_\varepsilon) \cap \mathcal{H}^1_0(\Omega_\varepsilon) \) (\( \Omega_\varepsilon \) is the region obtained by moving the \( \varepsilon Q \) along \( r(s) \) and, for each \( 0 < \varepsilon < 1 \), we consider \( \mathbf{A} \) restricted to \( \Omega_\varepsilon \)). We study the sequence \( H_\varepsilon \) in the limit \( \varepsilon \to 0 \). For this it is necessary to make some renormalization, for example, we need to control the transverse oscillations as \( \varepsilon \to 0 \). An interesting point is that even in the presence of a vector potential we are going to control these oscillations by subtracting \( \lambda_0/\varepsilon^2 \) from \( H_\varepsilon \), where \( \lambda_0 \) is the first (i.e., the lowest) eigenvalue of the Dirichlet Laplacian (no magnetic field) restricted to \( Q \). Namely,

\[
-\Delta u_0 = \lambda_0 u_0, \quad u_0 \in \mathcal{H}^1_0(Q), \quad u_0 \geq 0, \quad \int_Q |u_0|^2 dy = 1. \tag{1}
\]

\( u_0 \) denotes the normalized eigenfunction associated with \( \lambda_0 \). Recall that \( \lambda_0 > 0 \) and it is a simple eigenvalue.

Now, consider the one-dimensional operator

\[
(G_0 w)(s) := ( - i \partial_s - \langle \mathbf{A}(r(s)), T(s) \rangle )^2 w(s) + \left[ C(Q)(\tau + \alpha')^2(s) - \frac{k^2(s)}{4} \right] w(s),
\]

\( \text{dom } G_0 = \mathcal{H}^2(S) \), where \( C(Q) \) is a number that depends only on the region \( Q \) and \( T(s) \) is the tangent vector to the curve \( r \) at the position \( r(s) \); \( \langle \cdot, \cdot \rangle \) denotes the usual scalar product in \( \mathbb{R}^3 \). Our main application here says that

\[
H_\varepsilon - \frac{\lambda_0}{\varepsilon^2} \mathbf{1} \xrightarrow{\varepsilon \to 0} G_0 \tag{2}
\]

in a norm-resolvent sense; see Theorem 4 for a precise formulation. To prove this convergence we use the variational technique of \( \Gamma \)-convergence of quadratic forms in complex Hilbert spaces. Thus, in Section 2 we make the necessary generalizations to complex spaces in order to combine the corresponding strong and weak \( \Gamma \)-convergences with the operator convergence (2). In Section 3 we show some steps of the construction of the region where the problem is considered, the quadratic forms, and appropriate change of variables and renormalization. We also comment about a suitable gauge transform related to the magnetic potential \( \mathbf{A} \). In Section 4 we present the main results and the Section 5 is intended to prove them.
As usual in the context of (Dirichlet) reduction of dimension, we subtract the diverging coefficient in (2), but we would like to point that another renormalization (maybe more natural) can be performed. Hence, in Section 6 we discuss the possibility of a “magnetic renormalization” and show, under additional hypotheses, that the same effective operator is reached in the limit \( \varepsilon \to 0 \).

2 \( \Gamma \)-convergence in complex Hilbert spaces

As already mentioned in the Introduction, we consider a family of (uniformly) lower bounded self-adjoint operators \( T_\varepsilon \) \((\varepsilon > 0)\) with domain \( \text{dom} \ T_\varepsilon \) in a complex separable Hilbert space \( (\mathcal{H}, \langle \cdot , \cdot \rangle) \). We denote by \( b_\varepsilon \) the corresponding closed sesquilinear forms, and want to study the limit \( T \) (resp. \( b \)) of \( T_\varepsilon \) (resp. \( b_\varepsilon \)) as \( \varepsilon \to 0 \). The domain of \( T \) will not be supposed to be dense in \( \mathcal{H} \) and its closure will be denoted by \( \mathcal{H}_0 = \overline{\text{dom} \ T} \) (with \( \text{rng} \ T \subset \mathcal{H}_0 \)); usually this is indicated by simply saying that “\( T \) is self-adjoint in \( \mathcal{H}_0 \).”

As usual, the real-valued function \( \zeta \mapsto b(\zeta, \zeta) \) will be simply denoted by \( b(\zeta) \) and called the associated quadratic form with \( b(\zeta, \eta) \). It will be assumed that \( b \) is positive (or lower bounded in general) and \( b(\zeta) = \infty \) if \( \zeta \) does not belong to its domain \( \text{dom} \ b \); this is important in order to guarantee that in some cases \( b \) is lower semicontinuous, which is equivalent to \( b \) be the sesquilinear form generated by a positive self-adjoint operator \( T \), that is,

\[
b(\zeta, \eta) = \langle T^{1/2} \zeta, T^{1/2} \eta \rangle, \quad \zeta, \eta \in \text{dom} \ b = \text{dom} \ T^{1/2};
\]

see Theorem 9.3.11 in [4]. By allowing \( b(\zeta) = \infty \) one has a handy way to work in the larger space \( \mathcal{H} \) instead of only in \( \mathcal{H}_0 = \overline{\text{dom} \ T} \).

**Definition 1.** The sequence \( f_\varepsilon : \mathcal{H} \to \mathbb{R} \) strongly \( \Gamma \)-converges to \( f \) (that is, \( f_\varepsilon \xrightarrow{\text{SF}} f \)) iff the following two conditions are satisfied:

i) For every \( \zeta \in \mathcal{H} \) and every \( \zeta_\varepsilon \to \zeta \) in \( \mathcal{H} \) one has

\[
f(\zeta) \leq \liminf_{\varepsilon \to 0} f_\varepsilon(\zeta_\varepsilon).
\]

ii) For every \( \zeta \in \mathcal{H} \) there exists a sequence \( \zeta_\varepsilon \to \zeta \) in \( \mathcal{H} \) such that

\[
f(\zeta) = \lim_{\varepsilon \to 0} f_\varepsilon(\zeta_\varepsilon).
\]

**Remark 1.** If instead of strong convergence \( \zeta_\varepsilon \to \zeta \) one considers weak convergence \( \zeta_\varepsilon \rightharpoonup \zeta \) in Definition 1, then one has a characterization of \( f_\varepsilon \xrightarrow{\text{WF}} f \), that is, \( f_\varepsilon \) weakly \( \Gamma \)-converges to \( f \).

Now we state, in an appropriate form, the main result relating strong resolvent convergence of self-adjoint operators and \( \Gamma \)-convergence of the associated sesquilinear forms.

**Theorem 1.** Let \( b_\varepsilon, b \) be positive (or uniformly lower bounded) closed sesquilinear forms in the complex Hilbert space \( \mathcal{H} \), and \( T_\varepsilon, T \) the corresponding associated positive self-adjoint operators. Then the following statements are equivalent:
i) \( b_\varepsilon \underrightarrow{SF} b \) and, for each \( \zeta \in \mathcal{H} \), \( b(\zeta) \leq \liminf_{\varepsilon \to 0} b_\varepsilon(\zeta) \), \( \forall \zeta \to \zeta \) in \( \mathcal{H} \).

ii) \( b_\varepsilon \underrightarrow{SF} b \) and \( b_\varepsilon \underrightarrow{WT} b \).

iii) \( b_\varepsilon + \lambda \underrightarrow{SF} b + \lambda \) and \( b_\varepsilon + \lambda \underrightarrow{WT} b + \lambda \), for some \( \lambda > 0 \) (and so for all \( \lambda \geq 0 \)).

iv) \( T_\varepsilon \) converges to \( T \) in the strong resolvent sense in \( \mathcal{H}_0 = \overline{\text{dom} \ T} \subset \mathcal{H} \), that is,

\[
\lim_{\varepsilon \to 0} R_{-\lambda}(T_\varepsilon) \zeta = R_{-\lambda}(T)P_0 \zeta, \quad \forall \zeta \in \mathcal{H}, \forall \lambda > 0.
\]

where \( P_0 \) is the orthogonal projection onto \( \mathcal{H}_0 \).

Now we provide the necessary modifications so that the proofs of Theorem 13.6 and Corollary 13.7 in [3] can be replicated in order to include the case of complex Hilbert spaces, and so to conclude Theorem \[ \square \] above. There are two main points to regard. The first one is the replacement, in many instances, of terms of the form \( 2\langle \eta, \cdot \rangle \) in real-space functionals by \( \langle \eta, \cdot \rangle + \langle \cdot, \eta \rangle \); although this substitution is quite natural, there are few nuances in the proofs (see Proposition \[ \square \] ahead). Further, the proofs also help to elucidate the connection between forms, operator actions and domains on the one hand, and minimalization of suitable functionals on the other hand; this sheds some light on the role played by \( \Gamma \)-convergence in the convergence of self-adjoint operators.

**Proposition 1.** Let \( b \geq 0 \) be a closed sesquilinear form in the complex Hilbert space \( \mathcal{H} \), \( T \geq 0 \) the self-adjoint operator associated with \( b \) and \( P_0 \) be the orthogonal projection onto \( \mathcal{H}_0 = \overline{\text{dom} \ T} \subset \mathcal{H} \). Then \( \zeta \in \text{dom} \ T \) and \( T\zeta = P_0 \eta \) iff \( \zeta \) is a minimum point (also called minimizer) of the functional

\[ g: \mathcal{H} \to \mathbb{R}, \quad g(\zeta) = b(\zeta) - \langle \eta, \zeta \rangle - \langle \zeta, \eta \rangle. \]

**Proof.** Assume that \( \zeta \in \text{dom} \ T \) and \( T\zeta = P_0 \eta \). Note that \( g(0) = 0 \), so that the minimum of \( g \) is \( < \infty \). If \( \varrho \in \mathcal{H} \setminus \text{dom} \ b \), then \( g(\varrho) = \infty \) so that we can assume that \( \varrho \in \text{dom} \ b \); thus \( \varphi = \varrho - \zeta \in \text{dom} \ b \subset \mathcal{H}_0 \) and

\[
b(\varrho) = b(\zeta + (\varrho - \zeta)) = b(\zeta) + b(\varphi) + b(\zeta, \varphi) + b(\varphi, \zeta)
\geq b(\zeta) + \langle T\zeta, \varphi \rangle + \langle \varphi, T\zeta \rangle
= b(\zeta) + \langle P_0 \eta, \varphi \rangle + \langle \varphi, P_0 \eta \rangle
= b(\zeta) + \langle \eta, \varphi \rangle + \langle \varphi, \eta \rangle
= b(\zeta) + \langle \eta, \varrho - \zeta \rangle + \langle \varrho - \zeta, \eta \rangle.
\]

Hence \( b(\zeta) - \langle \eta, \zeta \rangle - \langle \zeta, \eta \rangle \leq b(\varrho) - \langle \eta, \varrho \rangle - \langle \varrho, \eta \rangle \), which is equivalent to \( g(\zeta) \leq g(\varrho) \). Since \( \varrho \) was arbitrary, \( \zeta \) is a minimum point of \( g \). Suppose now that \( g(\zeta) \leq g(\varrho) \), for all \( \varrho \in \mathcal{H} \), that is, \( \zeta \) is a minimum point of \( g \). Since \( g(\zeta) \leq g(0) = 0 \), it follows that \( 0 \leq b(\zeta) \leq \langle \eta, \zeta \rangle + \langle \zeta, \eta \rangle < \infty \) and so \( \zeta \in \text{dom} \ b \). The hypothesis \( g(\zeta) \leq g(\varrho) \) amounts to

\[
b(\varrho) \geq b(\zeta) + \langle \eta, \varrho - \zeta \rangle + \langle \varrho - \zeta, \eta \rangle, \quad \forall \varrho.
\]

Now for \( \varphi \in \text{dom} \ b \) and \( z \in \mathbb{C} \) fixed, this inequality implies

\[
b(\zeta) + |z|^2 b(\varphi) + zb(\zeta, \varphi) + \overline{z} b(\varphi, \zeta) = b(\zeta + z\varphi)
\geq b(\zeta) + z\langle \eta, \varphi \rangle + \overline{z} \langle \varphi, \eta \rangle.
\]
Choosing \( z = t > 0 \) yields

\[
tb(\varphi) + b(\zeta, \varphi) + b(\varphi, \zeta) \geq \langle \eta, \varphi \rangle + \langle \varphi, \eta \rangle,
\]
and taking \( t \to 0 \) one finds

\[
b(\zeta, \varphi) + b(\varphi, \zeta) \geq \langle \eta, \varphi \rangle + \langle \varphi, \eta \rangle.
\]

By considering \( z = t < 0 \) and then \( t \to 0 \) one gets the opposite inequality, and so the first relation

\[
b(\zeta, \varphi) + b(\varphi, \zeta) = \langle \eta, \varphi \rangle + \langle \varphi, \eta \rangle.
\]

By taking successively \( z = it \) with \( t > 0 \) and \( t < 0 \), then \( t \to 0 \) in both cases, one gets

\[
b(\zeta, \varphi) - b(\varphi, \zeta) = \langle \eta, \varphi \rangle - \langle \varphi, \eta \rangle.
\]

Add these two relations to obtain

\[
b(\zeta, \varphi) = \langle \eta, \varphi \rangle = \langle P_0 \eta, \varphi \rangle, \quad \forall \varphi \in \text{dom} \ b,
\]
and so conclude that \( \zeta \in \text{dom} \ T \) and \( T \zeta = P_0 \eta \) (see page 101 in [4]). This finishes the proof of the proposition.

The second main technical point we need to prove Theorem [4] in the case of complex Hilbert spaces is the following complex version of Proposition 11.9 in [3].

**Proposition 2.** Let \( \mathcal{H} \) be a complex Hilbert space and \( F : \mathcal{H} \to [0, \infty] \). If this functional \( F \) satisfies

\begin{itemize}
  
  \item [a)] \( F(0) = 0 \),
  
  \item [b)] \( F(t\zeta) \leq t^2 F(\zeta) \), for all \( \zeta \in \mathcal{H} \) and all \( t \geq 0 \),
  
  \item [c)] \( F(\zeta + \eta) + F(\zeta - \eta) \leq 2F(\zeta) + 2F(\eta) \), for all \( \zeta, \eta \in \mathcal{H} \),
  
  \item [d)] \( F(i\zeta) = F(\zeta) \), for all \( \zeta \in \mathcal{H} \),
\end{itemize}

then \( F \) is a quadratic form on \( \mathcal{H} \). Conversely, if \( F : \mathcal{H} \to [0, \infty] \) is a quadratic form, then it satisfies \( a), b), c), d) \) and, in addition,

\begin{itemize}
  
  \item [e)] \( F(z\zeta) = |z|^2 F(\zeta) \), for all \( \zeta \in \mathcal{H} \) and all \( z \in \mathbb{C} \),
  
  \item [f)] \( F(\zeta + \eta) + F(\zeta - \eta) = 2F(\zeta) + 2F(\eta) \), for all \( \zeta, \eta \in \mathcal{H} \).
\end{itemize}

**Proof.** If we first restrict \( F \) to real scalars and keep the notation \( F \) (so \( d) \) becomes meaningless), then by Proposition 11.9 of [3] (since \( a), b), c) \) hold true) this restriction is the quadratic form associated with a real sesquilinear form \( B : Y \times Y \to \mathbb{R}, Y = \{ \zeta \in \mathcal{H} : F(\zeta) < \infty \} \), given by

\[
B(\zeta, \eta) = \frac{1}{4} (F(\zeta + \eta) - F(\zeta - \eta)).
\]

Note that \( B(\zeta) := B(\zeta, \zeta) = F(\zeta) \) and, in particular, \( B(\zeta, \eta) = B(\eta, \zeta) \), \( B(t\zeta, s\eta) = tsB(\zeta, \eta) \), for all \( \zeta, \eta \in Y \), for all \( t, s \in \mathbb{R} \). Further, except \( d) \), \( B(\zeta) \) satisfies all items \( a), \cdots, f) \) but with the restriction \( z \in \mathbb{R} \) in \( e) \).
Our task now is to introduce an appropriate complex version of $B$, also defined on $Y$. To this end first extend $B$ by considering the original $F$ (i.e., without the restriction to real scalars) in the above expression, then define

$$b(\zeta, \eta) := B(\zeta, \eta) - iB(\zeta, i\eta),$$

and we will check that it works, that is, that $b$ is a (complex) sesquilinear form and $b(\zeta) = F(\zeta)$, for all $\zeta$. The motivation for this expression for $b$ comes from the following remark: if $u : Y \to \mathbb{C}$ is a linear functional, then $u(i\zeta) = \text{Re} \ u(i\zeta) + i\text{Im} \ u(i\zeta) = i\text{Re} \ u(\zeta) - \text{Im} \ u(\zeta)$, that is, the relation $\text{Im} \ u(\zeta) = -\text{Re} \ u(i\zeta)$ is valid (recall that $b$ must be linear in the second variable). By d) and the definitions of $B$ and $b$ it follows that

- $B(i\zeta, i\eta) = B(\zeta, \eta)$ and $b(i\zeta, i\eta) = b(\zeta, \eta), \forall \zeta, \eta \in Y$. In particular item d) holds for $b$.

- For all $\zeta, \eta$:
  $$b(\zeta, i\eta) = B(\zeta, i\eta) - iB(\zeta, -\eta) = B(\zeta, i\eta) + iB(\zeta, \eta)$$
  $$= i[b(\zeta, \eta) - iB(\zeta, i\eta)] = ib(\zeta, \eta)$$

- For all $\zeta, \eta$:
  $$b(\eta, \zeta) = B(\eta, \zeta) - iB(\eta, i\zeta) = B(\zeta, \eta) - iB(i\zeta, \eta)$$
  $$= B(\zeta, \eta) - iB(-\zeta, i\eta) = B(\zeta, \eta) + iB(\zeta, i\eta) = b(\zeta, \eta).$$

- For all $t, s \in \mathbb{R}$ and $\zeta, \eta \in Y$:
  $$b(\zeta, (t + is)\eta) = b(\zeta, t\eta) + b(\zeta, is\eta)$$
  $$= tb(\zeta, \eta) + isb(\zeta, \eta) = (t + is)b(\zeta, \eta).$$

Together with the above relations this also implies $b(z\zeta) = |z|^2b(\zeta), \forall z \in \mathbb{C}$, that is, item e) holds for $b$.

Finally, for $\zeta \in Y$ and $z \in \mathbb{C}$, $b(z\zeta) = b(z\zeta, z\zeta) = B(z\zeta, z\zeta) - iB(z\zeta, iz\zeta)$, and by selecting $z = i$ together with item d), it follows that

$$b(i\zeta) = b(\zeta),$$
$$B(i\zeta, i\zeta) - iB(i\zeta, -i\zeta) = B(\zeta, i\zeta) - iB(\zeta, i\zeta),$$
$$B(i\zeta, i\zeta) + iB(\zeta, i\zeta) = B(\zeta, i\zeta) - iB(\zeta, i\zeta),$$

so that $2iB(\zeta, i\zeta) = B(\zeta, i\zeta) - B(i\zeta, i\zeta)$. Since $B(\cdot) \text{ is real}$, it is found that $B(\zeta, i\zeta) = 0$ and so

$$b(\zeta) = B(\zeta, \zeta) - iB(\zeta, i\zeta) = B(\zeta, \zeta) = F(\zeta).$$

This implies that $b$ satisfies $a), b), c), f)$ since $F$ does, and the proof of the proposition is completed. \(\square\)

The above results allow us to prove the following complex versions of important results previously proven for real Hilbert spaces and presented in Dal Maso’s book. By taking into account the above propositions, the proofs are simple variations of their counterparts in the real case, and so they will be omitted.
Proposition 3. Let \( T : \text{dom} \ T \to \mathcal{H} \) be a positive self-adjoint operator, \( \text{dom} \ T = \mathcal{H}_0 \), and \( b^T : \mathcal{H} \to \mathbb{R} \) the quadratic form generated by \( T \). Then

\[
b^T(\zeta) = \sup_{\eta \in \text{dom} \ T} \left[ \langle T\eta, \zeta \rangle + \langle \zeta, T\eta \rangle - 2 \langle T\eta, \eta \rangle \right],
\]

for all \( \zeta \in \mathcal{H}_0 \) and \( b^T(\zeta) = \infty \) if \( \zeta \in \mathcal{H} \setminus \mathcal{H}_0 \).

Remark 2. The main difference in the proof of Proposition 3 with respect to the real case (see Theorem 12.21 in \cite{3}) is the following. For \( \zeta \in \mathcal{H}_0 \) denote

\[
F(\zeta) = \sup_{\eta \in \text{dom} \ T} \left[ \langle T\eta, \zeta \rangle + \langle \zeta, T\eta \rangle - 2 \langle T\eta, \eta \rangle \right]
\]

and one needs to check that \( F \) is a quadratic form, and a way of doing this is to employ our Proposition 2 in particular to check

\[
F(i\zeta) = \sup_{\eta \in \text{dom} \ T} \left[ \langle T\eta, i\zeta \rangle + \langle i\zeta, T\eta \rangle - 2 \langle T\eta, \eta \rangle \right] = F(\zeta).
\]

By using the above proposition one gets the following complex version of Theorem 13.5 in \cite{3}:

**Theorem 2.** Let \( b_\varepsilon, b \geq \beta > 0 \) be sesquilinear forms on the complex \( \mathcal{H} \) and \( T_\varepsilon, T \geq \beta 1 \) the corresponding associated self-adjoint operators, and let \( \text{dom} \ T = \mathcal{H}_0 \subset \mathcal{H} \). Let \( P_0 \) denote the orthogonal projection onto \( \mathcal{H}_0 \). Then the following statements are equivalent:

i) \( b_\varepsilon \xrightarrow{\text{WT}} b \).

ii) \( R_0(T_\varepsilon) \) converges weakly to \( R_0(T)P_0 \).

With such “complex” tools at hand, the proof of Theorem 2 follows the same steps of the proof of its real counterpart, i.e., Theorem 13.6 and Corollary 13.7 in \cite{3}.

Now we state sufficient conditions to obtain norm resolvent convergence of operators from \( \Gamma \)-convergence. The following theorem was proven in \cite{5}, the proof for complex Hilbert spaces is similar and doesn’t require further comments.

**Proposition 4.** Let \( \mathcal{H} \) be a real or complex Hilbert space, \( b_\varepsilon, b \geq \beta > -\infty \) be closed sesquilinear forms and \( T_\varepsilon, T \geq \beta 1 \) the corresponding associated self-adjoint operators, and let \( \text{dom} \ T = \mathcal{H}_0 \subset \mathcal{H} \). Assume that the following three conditions hold:

a) \( b_\varepsilon \xrightarrow{\text{SF}} b \) and \( b_\varepsilon \xrightarrow{\text{WT}} b \).

b) The resolvent operator \( R_{-\lambda}(T) \) is compact in \( \mathcal{H}_0 \) for some real number \( \lambda > |\beta| \).

c) There exists a Hilbert space \( \mathcal{K} \), compactly embedded in \( \mathcal{H} \), so that if \( (\psi_\varepsilon) \) is bounded in \( \mathcal{H} \) and the sequence \( (b_\varepsilon(\psi_\varepsilon)) \) is also bounded, then \( (\psi_\varepsilon) \) is a bounded subset of \( \mathcal{K} \).

Then, \( T_\varepsilon \) converges in norm resolvent sense to \( T \) in \( \mathcal{H}_0 \) as \( \varepsilon \to 0 \).
2.1 Norm convergence of quadratic forms

In some situations the convergence of quadratic forms may also imply the norm resolvent convergence of the corresponding operators. This subject was discussed in [7] for real Hilbert spaces. In the following, we (re)state and prove a complex version of a result in [7] which will be useful in this work; we also correct an imprecision in the previous proof.

**Theorem 3.** Let \((b_\varepsilon)_\varepsilon\), \((m_\varepsilon)_\varepsilon\) be two sequences of positive and closed sesquilinear quadratic forms in a complex Hilbert space \(\mathcal{H}\) with \(\text{dom } b_\varepsilon = \text{dom } m_\varepsilon = \mathcal{D}\), for all \(\varepsilon > 0\), and \(B_\varepsilon, M_\varepsilon\) the self-adjoint operators associated with \((b_\varepsilon)_\varepsilon\) and \((m_\varepsilon)_\varepsilon\), respectively. Suppose that there is \(\lambda > 0\) so that \(b_\varepsilon, m_\varepsilon \geq \lambda\), for all \(\varepsilon > 0\), and

\[
|b_\varepsilon(\psi) - m_\varepsilon(\psi)| \leq q(\varepsilon) m_\varepsilon(\psi), \quad \forall \psi \in \mathcal{D},
\]

with \(q(\varepsilon) \to 0\) as \(\varepsilon \to 0\). Then, there exists \(C > 0\) so that, for \(\varepsilon > 0\) small enough,

\[
\|B_\varepsilon^{-1} - M_\varepsilon^{-1}\| \leq C q(\varepsilon).
\]

**Proof.** Let \(b_\varepsilon(u, \tilde{u})\) and \(r_\varepsilon(u, \tilde{u})\) the sesquilinear forms associated with \(b_\varepsilon(u)\) and \(m_\varepsilon(u)\), respectively. Recall the polarization identity

\[
b_\varepsilon(u, \tilde{u}) = \frac{1}{4} [b_\varepsilon(u + \tilde{u}) - b_\varepsilon(u - \tilde{u}) - i b_\varepsilon(u + i \tilde{u}) + i b_\varepsilon(u - i \tilde{u})],
\]

which will be used ahead.

Note that condition (3) implies

\[
(1 - q(\varepsilon))m_\varepsilon(\psi) \leq b_\varepsilon(\psi) \leq (1 + q(\varepsilon))m_\varepsilon(\psi), \quad \forall \psi \in \mathcal{D}.
\]

As \(q(\varepsilon) \to 0\), there exist \(\varepsilon_0 > 0\) and a number \(C_1 > 0\) so that \(m_\varepsilon(\psi) \leq C_1 b_\varepsilon(\psi)\), for all \(\varepsilon < \varepsilon_0\) and \(\psi \in \mathcal{D}\).

For \(u, \tilde{u} \in \mathcal{D}\), one has

\[
\left| \langle B_{\varepsilon}^{1/2} u, B_{\varepsilon}^{1/2} \tilde{u} \rangle - \langle M_{\varepsilon}^{1/2} u, M_{\varepsilon}^{1/2} \tilde{u} \rangle \right| = |b_\varepsilon(u, \tilde{u}) - m_\varepsilon(u, \tilde{u})|
\]

\[
= \left( \frac{1}{4} \right) |b_\varepsilon(u + \tilde{u}) - m_\varepsilon(u + \tilde{u}) - b_\varepsilon(u - \tilde{u}) + m_\varepsilon(u - \tilde{u})|
\]

\[
- i b_\varepsilon(u + i \tilde{u}) + i m_\varepsilon(u + i \tilde{u}) + i b_\varepsilon(u - i \tilde{u}) - i m_\varepsilon(u - i \tilde{u})|
\]

\[
\leq \left( \frac{1}{4} \right) q(\varepsilon) [m_\varepsilon(u + \tilde{u}) + m_\varepsilon(u - \tilde{u}) + m_\varepsilon(u + i \tilde{u}) + m_\varepsilon(u - i \tilde{u})]
\]

\[
= q(\varepsilon) [m_\varepsilon(u) + m_\varepsilon(\tilde{u})]
\]

\[
\leq q(\varepsilon) [C_1 b_\varepsilon(u) + m_\varepsilon(\tilde{u})].
\]

Taking \(u = B_{\varepsilon}^{-1} g\) and \(\tilde{u} = M_{\varepsilon}^{-1} \tilde{g}\), with \(g, \tilde{g} \in L^2(\mathcal{H})\), one has

\[
\left| \langle (B_{\varepsilon}^{-1} - M_{\varepsilon}^{-1}) g, \tilde{g} \rangle \right| \leq q(\varepsilon) \left[ C_1 \langle B_{\varepsilon}^{-1} g, \tilde{g} \rangle + \langle M_{\varepsilon}^{-1} \tilde{g}, \tilde{g} \rangle \right]
\]

\[
\leq q(\varepsilon) \left[ C_1 \|B_{\varepsilon}^{-1}\| \|g\|^2 + \|M_{\varepsilon}^{-1}\| \|	ilde{g}\|^2 \right].
\]

Thus,

\[
\|B_{\varepsilon}^{-1} - M_{\varepsilon}^{-1}\| = \sup_{\|g\|=1} \left| \langle (B_{\varepsilon}^{-1} - M_{\varepsilon}^{-1}) g, g \rangle \right| \leq q(\varepsilon) \left[ C_1 \|B_{\varepsilon}^{-1}\| + \|M_{\varepsilon}^{-1}\| \right] \leq C q(\varepsilon),
\]

for some \(C > 0\). \(\Box\)
3 The model

The geometry of the domain

Let $S$ be a circle of length $l > 0$ and $r : S \to \mathbb{R}^3$ a closed and simple curve of class $C^3$ in $\mathbb{R}^3$ parameterized by its arc length parameter $s$. Just as in [1, 6], we assume that $r(s)$ is endowed with the Frenet trihedron consisting of orthogonal unit vectors $\{T(s), N(s), B(s)\}$ satisfying the system of Frenet equations (as usual, we take the tangent, normal and binormal vectors). We denote by $k(s)$ and $\tau(s)$ the curvature and torsion, respectively, of the curve $r$ at the position $r(s)$, and also suppose that $k, \tau \in L^\infty(S)$.

Let $Q$ be a nonempty open, bounded, connected and simply connected subset of $\mathbb{R}^2$, and with a smooth boundary. The set

$$\Omega = \{ x \in \mathbb{R}^3 : x = r(s) + y_2 N(s) + y_3 B(s), s \in S, y = (y_2, y_3) \in Q \}$$

is obtained by putting the region $Q$ along the curve $r(s)$. In each point $r(s)$ one also allows a rotation angle $\alpha(s)$ of the cross-section $Q$, and such rotation function is supposed to be of class $C^2$. Thus, the new region is given by

$$\Omega^\alpha = \{ x \in \mathbb{R}^3 : x = r(s) + y_2 N_\alpha(s) + y_3 B_\alpha(s), s \in S, y = (y_2, y_3) \in Q \},$$

where

$$N_\alpha(s) := \cos \alpha(s) N(s) + \sin \alpha(s) B(s),$$

$$B_\alpha(s) := -\sin \alpha(s) N(s) + \cos \alpha(s) B(s).$$

Now, we add a small parameter $\varepsilon > 0$ to obtain the sequence of regions

$$\Omega^\varepsilon = \{ x \in \mathbb{R}^3 : x = r(s) + \varepsilon y_2 N_\alpha(s) + \varepsilon y_3 B_\alpha(s), s \in S, y = (y_2, y_3) \in Q \},$$

which is “squeezed” to the curve $r(s)$ as $\varepsilon \to 0$.

Quadratic forms

As mentioned in the introduction of this work, we consider the vector magnetic potential $A = (A_1, A_2, A_3)$, where $A_j : \Omega \to \mathbb{R}, j = 1, 2, 3$, are real functions, so that $B = \nabla \times A$ is the corresponding magnetic field, i.e., the rotational of $A$. Now, consider the family of self-adjoint magnetic Schrödinger operators

$$H^\varepsilon_\alpha \psi = (-i\partial_s - A)^2 \psi = (-i\partial_{x_1} - A_1)^2 \psi + (-i\partial_{x_2} - A_2)^2 \psi + (-i\partial_{x_3} - A_3)^2 \psi,$$

dom $H^\varepsilon_\alpha = H^2(\Omega^\varepsilon) \cap H^1_0(\Omega^\varepsilon)$. $\partial_{x_j}$ denotes the partial derivative with respect to the coordinate $x_j$, and so on.

For the vector field $A$ we suppose initially that

$$A_j \in C^2(\Omega) \cap L^\infty(\Omega), \quad j = 1, 2, 3.$$  \hfill (4)
The family of quadratic forms associated with the operators $H^\alpha_\varepsilon$ is given by

$$b^\alpha_\varepsilon(\psi) := \int_{\Omega^\alpha_\varepsilon} |(-i\partial_x - A_1)\psi|^2 \, dx$$

$$= \int_{\Omega^\alpha_\varepsilon} \left(|(-i\partial_x_1 - A_1)\psi|^2 + |(-i\partial_x_2 - A_2)\psi|^2 + |(-i\partial_x_3 - A_3)\psi|^2 \right) \, dx,$$

with dom $b^\alpha_\varepsilon = \mathcal{H}^1_0(\Omega^\alpha_\varepsilon)$.

**Change of variables**

Now we are going to perform a change of variables so that the integration region in $b^\alpha_\varepsilon$, and consequently their domains, don’t depend on the parameter $\varepsilon > 0$. The change ahead is usual and details will be omitted; see [1, 5, 6].

For each $\varepsilon > 0$ consider the function

$$f^\alpha_\varepsilon : S \times Q \rightarrow \Omega^\alpha_\varepsilon$$

$$(s, y_2, y_3) \mapsto r(s) + \varepsilon y_2 N_\alpha(s) + \varepsilon y_3 B_\alpha(s),$$

and the unitary operator

$$U^\alpha_\varepsilon : L^2(\Omega^\alpha_\varepsilon) \rightarrow L^2(S \times Q, \beta_\varepsilon)$$

$$\psi \mapsto \varepsilon \psi \circ f^\alpha_\varepsilon,$$

where $\beta_\varepsilon(s, y) := 1 - \varepsilon k(s)\langle z_\alpha, y \rangle$ and $z_\alpha := (\cos \alpha, \sin \alpha)$ ($\beta_\varepsilon$ comes from the Riemannian metric defined by $f^\alpha_\varepsilon$, which is a global diffeomorphism for $\varepsilon > 0$ small enough).

We denote

$$\left( \begin{array}{c} \tilde{A}_1^\alpha(s, y) \\ \tilde{A}_2^\alpha(s, y) \\ \tilde{A}_3^\alpha(s, y) \end{array} \right) := \left( \begin{array}{c} T(s) \\ N(s) \\ B(s) \end{array} \right) \left( \begin{array}{c} (A_1 \circ f^\alpha_\varepsilon)(s, y) \\ (A_2 \circ f^\alpha_\varepsilon)(s, y) \\ (A_3 \circ f^\alpha_\varepsilon)(s, y) \end{array} \right),$$

$$\tilde{A}_1^\alpha(s, y) := \varepsilon \cos \alpha(s) \tilde{A}_2^\alpha(s, y) + \varepsilon \sin \alpha(s) \tilde{A}_3^\alpha(s, y),$$

$$\tilde{A}_2^\alpha(s, y) := -\varepsilon \sin \alpha(s) \tilde{A}_2^\alpha(s, y) + \varepsilon \cos \alpha(s) \tilde{A}_3^\alpha(s, y),$$

and, for $\varphi \in \mathcal{H}^1_0(S \times Q),$

$$\tilde{\partial}_y \varphi := (-i\partial_y_2 - \tilde{A}_2^\alpha(s, y)) \varphi,$$

$$\tilde{\partial}_y \varphi := (-i\partial_y_3 - \tilde{A}_3^\alpha(s, y)) \varphi.$$

From now on we consider the sequence $b^\alpha_\varepsilon + c$, with $c > \|k^2/4\|_{\infty}$ (the reason for this choice will be clear ahead). Some calculations show that the quadratic form $b^\alpha_\varepsilon + c$, after of the change given by $U^\alpha_\varepsilon$, can be written as

$$\tilde{b}^{\alpha, c}_\varepsilon(\varphi) := \int_{S \times Q} \frac{1}{\beta_\varepsilon} \left| -i\partial_\varphi - \beta_\varepsilon \tilde{A}_1^\alpha(s, y) \varphi - (\nabla_y \varphi, R_y)(\tau + \alpha') \right|^2 \, ds dy$$

$$+ \int_{S \times Q} \left( \frac{\beta_\varepsilon}{\varepsilon^2} |\tilde{\partial}_y \varphi|^2 + c \beta_\varepsilon |\varphi|^2 \right) \, ds dy,$$

10
The domain of each \( \tilde{b}^{\alpha,c} \) is the subspace \( \mathcal{H}_0^1(S \times Q) \) of the Hilbert space \( L^2(S \times Q, \beta_\epsilon(s,y)) \). However, it is convenient to work in \( L^2(S \times Q) \), that is, with the usual Lebesgue measure. Thus, we consider the isometry \( V_\epsilon^\alpha : L^2(S \times Q) \to L^2(S \times Q, \beta_\epsilon)^{1/2} \) (5).

Now, for \( v \in \mathcal{H}_0^1(S \times Q) \), we denote
\[
\tilde{\partial}_s v := (\tilde{\partial}_y \psi, R_y)(\tau + \alpha'(s)),
\]
where
\[
\tilde{A}_\epsilon(t, y) := \beta_\epsilon(t, y) \hat{A}_\epsilon(t, y) - \frac{i}{2} \frac{\partial \beta_\epsilon}{\partial s} - \frac{1}{2} \langle \nabla_y \beta_\epsilon, R_y \rangle (\tau + \alpha')(s).
\]

Applying the change of variables (5) to the quadratic form \( \tilde{b}^{\alpha,c} \), it is found that
\[
\tilde{g}_\epsilon^{\alpha,c}(v) = \int_{S \times Q} (1/\beta_\epsilon^2) \left| \tilde{\partial}_s v - \langle \nabla_y \psi, R_y \rangle (\tau + \alpha')(s) \right|^2
\]
\[
+ \frac{1}{\epsilon^2} \int_{S \times Q} |\tilde{\partial}_y \psi|^2 ds dy - \int_{S \times Q} (1/\beta_\epsilon^2) \frac{k^2(s)}{4} |v|^2 ds dy
\]
\[
+ c \int_{S \times Q} |v|^2 ds dy,
\]
where \( \text{dom} \tilde{g}_\epsilon^{\alpha,c} = \mathcal{H}_0^1(S \times Q) \) is now a subspace of \( L^2(S \times Q) \).

Besides allowing us to working in the Hilbert space \( L^2(S \times Q) \) with the usual measure, the unitary transformation (5) makes the curvature appears in the expression of the quadratic form (note the penultimate integral in the definition of \( \tilde{g}_\epsilon^{\alpha,c} \)). Now it is clear the role played by the constant \( c > 0 \): for \( \epsilon > 0 \) small enough, the quadratic forms \( \tilde{g}_\epsilon^{\alpha,c}(v) \) become positive.

**Renormalization of \( \tilde{g}_\epsilon^{\alpha,c} \)**

When the sequence of tubes is “squeezed” to the curve \( r(s) \), there are divergent eigenvalues due to the factor
\[
\frac{1}{\epsilon^2} \int_{S \times Q} |\tilde{\partial}_y \psi|^2 ds dy,
\]
which is directly related with the magnetic Laplacian restricted to the cross section \( Q \).

We renormalize this divergence by subtracting
\[
\frac{\lambda_0}{\epsilon^2} \int_{S \times Q} |\psi|^2 ds dy \tag{6}
\]
from \( \tilde{g}_\epsilon^{\alpha,c}(\psi) \). Recall that \( \lambda_0 \) is the first eigenvalue of the Dirichlet Laplacian in \( Q \) (see (1) in the introduction of this work). Thus, we pass to consider the sequence of
renormalized quadratic forms

\[ g_{\varepsilon}^{\alpha,c}(v) := \tilde{g}_{\varepsilon}^{\alpha,c}(v) - \int_{S \times Q} \frac{\lambda_0}{\varepsilon^2} |v|^2 \, ds \, dy \]

\[ = \int_{S \times Q} \left( \frac{1}{\varepsilon^2} |\tilde{\partial}_s v - \langle \nabla_y v, R y \rangle (\tau + \alpha')(s) |^2 \right) \, ds \, dy \]

\[ + \frac{1}{\varepsilon^2} \int_{S \times Q} \left( |\tilde{\partial}_y v|^2 - \lambda_0 |v|^2 \right) \, ds \, dy - \int_{S \times Q} \frac{1}{\varepsilon^2} \frac{k^2(s)}{4} |v|^2 \, ds \, dy \]

\[ + c \int_{S \times Q} |v|^2 \, ds \, dy, \]

with \( \text{dom } g_{\varepsilon}^{\alpha,c} = \mathcal{H}_0^1(S \times Q) \).

**Gauge transform.**

For the magnetic field \( A \) we are going to suppose, without loss of generality, that

\[ \langle N(s), A(r(s)) \rangle = \langle B(s), A(r(s)) \rangle = 0, \quad \forall s \in S. \quad (7) \]

In fact, let \( \tilde{A}_\varepsilon := (\tilde{A}_1^\varepsilon, \tilde{A}_2^\varepsilon, \tilde{A}_3^\varepsilon) \), by using the gauge transform

\[ \tilde{\Phi}_\varepsilon \mapsto \tilde{A}_\varepsilon - \nabla \Phi_\varepsilon, \]

with \( \Phi_\varepsilon(s, y) = y_2 \tilde{A}_2^\varepsilon(s, 0) + y_3 \tilde{A}_3^\varepsilon(s, 0) \), we can suppose \( \tilde{A}_2^\varepsilon(s, 0) = \tilde{A}_3^\varepsilon(s, 0) = 0 \), for all \( s \in S \), which implies the condition \( \tilde{A}_1 \). Due the periodicity (recall that \( r(s) \) is a closed curve), usually the vector potential in one-dimensional effective operators can not be gauged away, as it happens in case of unbounded tubes \([12]\).

Our study, in the next sections, will be conducted with the quadratic forms \( g_{\varepsilon}^{\alpha,c}(v) \); thus, for simplicity, we shall omit the indices \( \alpha \) and \( c \) from the notations. For example, \( g_{\varepsilon}^{\alpha,c} \) will be simply denoted by \( g_{\varepsilon} \).

4 **The main theorem**

In this section we present our application of the complex \( \Gamma \)-convergence discussed in Section 2. Recall that

\[ g_{\varepsilon}(v) = +\infty \quad \text{for} \quad v \in L^2(S \times Q) \setminus \mathcal{H}_0^1(S \times Q), \]

put

\[ C(Q) := \int_Q |\langle \nabla_y u_0, R y \rangle|^2 \, dy, \]

and recall that \( u_0 \) is a normalized eigenfunction corresponding to the first eigenvalue \( \lambda_0 \) of the Dirichlet Laplacian in \( Q \). Note that \( C(Q) \) depends only on the cross section \( Q \).

Consider the one-dimensional quadratic form

\[ g_0(w) := \int_S |(-i \partial_s - \langle A(r(s)), T(s) \rangle) w(s)|^2 \, ds \]

\[ + \int_S \left[ C(Q)(\tau + \alpha')^2(s) - \frac{k^2(s)}{4} + c \right] |w(s)|^2 \, ds, \]
with \( \text{dom } g_0 = \mathcal{H}^1(S) \). From \( g_0(w) \) we define a quadratic form on \( L^2(S \times Q) \):

\[
g(v) = \begin{cases} g_0(w) & \text{if } v = wu_0 \quad \text{with } w \in \text{dom } g_0 \\ +\infty & \text{otherwise} \end{cases}
\]  

\( (8) \)

We denote by \( G_\varepsilon \) and \( G \) the respective self-adjoint operators associated with the quadratic forms \( g_\varepsilon \) and \( g \). Our application is the following theorem.

**Theorem 4.** Under condition \( (7) \), the sequence of operators \( G_\varepsilon \) converges to \( G \) in the norm convergence sense as \( \varepsilon \to 0 \). More exactly,

\[
\| (G_\varepsilon - iI)^{-1} - (G - iI)^{-1} \| \to 0
\]

as \( \varepsilon \to 0 \).

Through the unitary transformation \( v(x,y) = w(s)u_0(y) \mapsto w(s) \), \( G \) can be identified with the one-dimensional operator

\[
(G_0w)(s) := (-i\partial_s - \langle A(r(s)), T(s) \rangle)^2w(s) + \left[ C(Q)(r + \alpha')^2(s) - \frac{k^2(s)}{4} + c \right] w(s),
\]

with \( \text{dom } G_0 = \mathcal{H}^2(S) \). Due to this identification, we say that there was a “reduction of dimension” in the limit \( \varepsilon \to 0 \). We can also note the presence of a potential in \( G_0 \) that came from the original magnetic potential, as well as a term that depends on geometric effects of the original region, as habitually is the case in such kind of problems without magnetic fields.

## 5 Proof of Theorem 4

To prove Theorem 4 we are going to apply Proposition 4 of Section 2. The first step is to show that the sequence \( g_\varepsilon \) strongly \( \Gamma \)-converges to \( g \). Observe that in our case the strong and weak \( \Gamma \)-convergences are equivalent because the region \( S \times Q \) is bounded.

Some important properties that we will use ahead are as follows:

1. For all function \( v \in \mathcal{H}^1_0(S \times Q) \), we have

\[
\int_Q ((\nabla_y v(s,y))^2 - \lambda_0 |v(s,y)|^2) \, dy \geq 0, \quad \text{a.e.}[s],
\]

and

\[
\int_Q (|\partial_y v(s,y)|^2 - \lambda_0 |v(s,y)|^2) \, dy \geq 0, \quad \text{a.e.}[s].
\]  

The first inequality follows from the definition of \( \lambda_0 \) and the second one is a consequence of (9) combined with the Diamagnetic Inequality [11].

2. The Dirichlet condition on the boundary \( \partial Q \) implies \( \int_Q \nabla_y u_0^2 \, dy = 0 \), which, by its turn, implies that

\[
\int_Q \langle u_0 \nabla_y u_0, Ry \rangle \, dy = 0.
\]
To show the strong $\Gamma$-convergence of the sequence $g_\varepsilon$ we will make use of some lemmas.

**Lemma 1.** If $v_\varepsilon \rightharpoonup v$ in $L^2(S \times Q)$ and $(g_\varepsilon(v_\varepsilon))_\varepsilon$ is a bounded sequence in $L^2(S \times Q)$, then $(\partial_\varepsilon v_\varepsilon)_\varepsilon$ and $(\nabla_y v_\varepsilon)_\varepsilon$ are bounded sequences in $L^2(S \times Q)$. Furthermore, $\partial_\varepsilon v_\varepsilon \rightharpoonup \partial_y v, \nabla_y v_\varepsilon \rightharpoonup \nabla_y v$ in $L^2(S \times Q)$ and $v \in H^1_0(S \times Q)$.

**Proof.** As $(g_\varepsilon(v_\varepsilon))_\varepsilon$ is a bounded sequence, there exists a number $D > 0$ so that

$$\limsup_{\varepsilon \to 0} \int_{S \times Q} \frac{1}{\partial_y^2} \left| \partial_\varepsilon v_\varepsilon - \langle \nabla_y v_\varepsilon, Ry \rangle (\tau + \alpha')(s) \right|^2 \, ds \, dy$$

$$\leq \limsup_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) \leq D.$$

Now, since $(v_\varepsilon)_\varepsilon$ is also a bounded sequence, we have

$$\limsup_{\varepsilon \to 0} \int_{S \times Q} \left| \partial_y v_\varepsilon \right|^2 \, ds \, dy$$

$$= \limsup_{\varepsilon \to 0} \left( \int_{S \times Q} \left| \partial_y v_\varepsilon \right|^2 \, ds \, dy + \int_{S \times Q} \partial_0 |v_\varepsilon|^2 \, ds \, dy \right)$$

$$\leq \limsup_{\varepsilon \to 0} D \varepsilon^2 + \int_{S \times Q} \lambda_0 |v_\varepsilon|^2 \, ds \, dy < \infty.$$

We have shown above that $((-i \partial_y - \tilde{A}_y^2) v_\varepsilon)_\varepsilon$ and $((-i \partial_y - \tilde{A}_y^2) v_\varepsilon)_\varepsilon$ are bounded sequences in $L^2(S \times Q)$. Since $(\tilde{A}_y^2 v_\varepsilon)$ and $(\tilde{A}_y^2 v_\varepsilon)$ are also bounded sequences in $L^2(S \times Q)$, we conclude that $(\nabla_y v_\varepsilon)_\varepsilon$ is a bounded sequence in $L^2(S \times Q)$. Similarly, $(\partial_\varepsilon v_\varepsilon)_\varepsilon$ is a bounded sequence in $L^2(S \times Q)$. Therefore, $(v_\varepsilon)_\varepsilon$ is a bounded sequence in $H^1_0(S \times Q)$. Thus, there exist $\phi \in H^1_0(S \times Q)$ and a subsequence of $(v_\varepsilon)_\varepsilon$, also denoted by $(v_\varepsilon)_\varepsilon$, so that $v_\varepsilon \rightharpoonup \phi$ in $H^1_0(S \times Q)$ (recall that Hilbert spaces are reflexive). As $v_\varepsilon \rightharpoonup v$ in $L^2(S \times Q)$, it follows that $v = \phi$, $\partial_\varepsilon v_\varepsilon \rightharpoonup \partial_y v, \nabla_y v_\varepsilon \rightharpoonup \nabla_y v$ in $L^2(S \times Q)$ and $v \in H^1_0(S \times Q)$. \qed

**Lemma 2.** Let $v_\varepsilon \rightharpoonup v$ be in $L^2(S \times Q)$ so that there exists $\limsup_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) < \infty$. Then, we can write $v(s, y) = w(s)u_0(y)$ with $w \in H^1(S)$.

**Proof.** In fact, by previous lemma, $\nabla_y v_\varepsilon \rightharpoonup \nabla_y v$ weakly in $L^2(S \times Q)$. Observe that also $\tilde{A}_y^2 v_\varepsilon \rightharpoonup 0$ and $\tilde{A}_y^2 v_\varepsilon \to 0$ weakly. Thus, $\partial_y v_\varepsilon \rightharpoonup \nabla_y v$ weakly in $L^2(S \times Q)$.

From the strong convergence of $(v_\varepsilon)_\varepsilon$ we have

$$\int_{S \times Q} |\nabla_y v|^2 \, ds \, dy \leq \liminf_{\varepsilon \to 0} \int_{S \times Q} |\partial_y v_\varepsilon|^2 \, ds \, dy$$

$$\leq \limsup_{\varepsilon \to 0} \int_{S \times Q} \lambda_0 |v_\varepsilon|^2 \, ds \, dy$$

$$= \lambda_0 \int_{S \times Q} |v|^2 \, ds \, dy.$$

This fact, combined with (3) above, tell us that

$$\int_{S \times Q} \left( |\nabla_y v|^2 - \lambda_0 |v|^2 \right) \, ds \, dy = 0.$$
Consider $f(s) := \int_Q \left( |\nabla_y v(s,y)|^2 - \lambda_0 |v(s,y)|^2 \right) \, dy$. Since $f(s) \geq 0$, the inequality above implies that $f = 0$ a.e.[$\mathcal{H}$]. Therefore, $v(s,y)$ is an eigenfunction associated with $\lambda_0$. As $\lambda_0$ is a simple eigenvalue, $v(s,y)$ is proportional to $u_0$. Thus, we can write $v(s,y) = w(s)u_0(y)$ with $w \in \mathcal{H}_1(S)$ (since $v \in \mathcal{H}_0^1(S \times Q)$).

**Proof of Theorem 4:** Let $v \in L^2(S \times Q)$ and $v_\varepsilon \to v$ in $L^2(S \times Q)$. We are going to show that $\lim_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) \geq g(v)$. If $\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) = \infty$, then $\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) \geq g(v)$.

Suppose now that $\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) < \infty$. Passing to a subsequence, if necessary, we can suppose $\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) = \lim_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) < \infty$.

Lemma 4 ensures that $\partial_s v_\varepsilon \to \partial_s v$ and $\nabla_y v_\varepsilon \to \nabla_y v$ weakly in $L^2(S \times Q)$. As $\tilde{A}_1^\varepsilon(s,y) \to (A(r(s)), T(s))$ uniformly, we have

$$\tilde{\partial}_s v_\varepsilon \to (-i \partial_s - \langle A(r(s)), T(s) \rangle) v$$

weakly in $L^2(S \times Q)$. By recalling that $(\tau + \alpha') \in L^\infty(S)$, we have

$$\partial_s v_\varepsilon - \langle \nabla_y v_\varepsilon, Ry \rangle (\tau + \alpha')(s) \to (-i \partial_s - \langle A(r(s)), T(s) \rangle) v - \langle \nabla_y v, Ry \rangle (\tau + \alpha')(s)$$

in $L^2(S \times Q)$. By Lemma 1 $v \in H_0^1(S \times Q)$ and we can write $v(s,y) = w(s)u_0(y)$ with $w \in \mathcal{H}_1(S)$.

The above remarks, together with properties (1) and (2), show that

$$\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) \geq \liminf_{\varepsilon \to 0} \int_{S \times Q} \frac{1}{\beta_\varepsilon^2} \left| \partial_s v_\varepsilon - \langle \nabla_y v_\varepsilon, Ry \rangle (\tau + \alpha')(s) \right|^2 \, ds \, dy$$

$$+ \liminf_{\varepsilon \to 0} \int_{S \times Q} \frac{k_\varepsilon^2(s)}{4\beta_\varepsilon^2} |v_\varepsilon|^2 \, ds \, dy + \liminf_{\varepsilon \to 0} \int_{S \times Q} c |v_\varepsilon|^2 \, ds \, dy$$

$$\geq \int_{S \times Q} \left| (-i \partial_s - \langle A(r(s)), T(s) \rangle) v - \langle \nabla_y v, Ry \rangle (\tau + \alpha')(s) \right|^2 \, ds \, dy$$

$$+ \int_{S \times Q} \left( c - \frac{k_\varepsilon^2(s)}{4} \right) |v|^2 \, ds \, dy$$

$$= \int_S \left\{ (-i \partial_s - \langle A(r(s)), T(s) \rangle )w^2 + C(Q)(\tau + \alpha')^2(s) - \frac{k_\varepsilon^2(s)}{4} + c \right\} |w|^2 \, ds$$

$$= g_0(\omega) = g(v).$$

Now we are going to show that for each $v \in L^2(S \times Q)$ there exists a sequence $(v_\varepsilon)_\varepsilon$ in $L^2(S \times Q)$ so that $v_\varepsilon \to v$ in $L^2(S \times Q)$ and $\lim_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) = g(v)$. First we consider the particular case of $v = wu_0$ with $w \in \mathcal{H}_1(S)$. In this situation we take the sequence $(v_\varepsilon)_\varepsilon$ with, for each $\varepsilon > 0$, $v_\varepsilon := wu_0$. We have $v_\varepsilon \to v$ in $L^2(S \times Q)$ and we see that

$$\lim_{\varepsilon \to 0} \int_{S \times Q} \left( 1/\beta_\varepsilon^2 \right) \left| \partial_s (wu_0) - w \langle \nabla_y u_0, Ry \rangle (\tau + \alpha')(s) \right|^2 \, ds \, dy$$

$$= \int_S \left\{ (-i \partial_s - \langle A(r(s)), T(s) \rangle )w^2 + C(Q)(\tau + \alpha')^2(s) |w|^2 \right\} \, ds$$
In this section we perform a different renormalization of the quadratic forms $\tilde{\mathcal{A}}^3$. A different renormalization operator is reached in the limit $\varepsilon \to 0$. We underline that the renormalization ahead would be the first choice for the magnetic reduction of dimension, since it takes into account the presence of the magnetic field in the cross section, in contrast with the renormalization we took in previous sections.

Recalling the definitions of $\tilde{\mathcal{A}}^3$, $\tilde{\mathcal{A}}^3$ and condition (7), we obtain

$$
\lim_{\varepsilon \to 0} \frac{1}{\varepsilon^2} \int_{S \times Q} \left( |iw\partial_y u_0 - \tilde{\mathcal{A}}_\varepsilon^3 u_0|^2 + |iw\partial_y u_0 - \tilde{\mathcal{A}}_\varepsilon^3 w_0|^2 - \lambda_0 |w_0|^2 \right) ds dy
$$

$$
= \lim_{\varepsilon \to 0} \frac{1}{\varepsilon^2} \int_{S \times Q} \left( |\tilde{\mathcal{A}}^3_\varepsilon|^2 + |\tilde{\mathcal{A}}^3_\varepsilon|^2 \right) |w|^2 |u_0|^2 ds dy
$$

$$
= \int_S \left( |(N(s), A(r(s)))|^2 + |(B(s), A(r(s)))|^2 \right) |w|^2 ds = 0.
$$

Thus, $\lim_{\varepsilon \to 0} g_\varepsilon(v) = g(wu_0)$.

Now, consider the case $v \in L^2(S \times Q) \setminus \{wu_0 : w \in \mathcal{H}^1(S)\}$. By definition $g(v) = \infty$. Let $\varepsilon_n$ be a sequence so that $v \varepsilon_n \to v$ in $L^2(S \times Q)$. In this case, $\lim_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) = \infty$. In fact, if we suppose that $\lim_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) < \infty$, by Lemmas 1 and 2 we should have $v = wu_0$, with $w \in \mathcal{H}^1(S)$, which does not occur. Therefore, $\lim_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) = \infty = g(v)$.

We have shown above that the sequence of quadratic forms $g_\varepsilon$ Γ-converges to $g$ in the strong sense. To conclude the weak Γ-convergence we need only to show the following: if $v_\varepsilon \to v$ in $L^2(S \times Q)$, then $\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) \geq g(v)$. If $\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) = \infty$, there is nothing to prove. If $\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) < \infty$, we can suppose that

$$
\liminf_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) = \lim_{\varepsilon \to 0} g_\varepsilon(v_\varepsilon) < \infty.
$$

Lemma 1 ensures that $(v_\varepsilon)_\varepsilon$ is bounded in $\mathcal{H}^1_0(S \times Q)$. By Rellich-Kondrachov Theorem, the space $\mathcal{H}^1_0(S \times Q)$ is compactly embedded in $L^2(S \times Q)$ and so there is a subsequence of $(v_\varepsilon)_\varepsilon$, also denoted by $(v_\varepsilon)_\varepsilon$, so that $v_\varepsilon \to v$. Now, the proof follows the same steps of strong Γ-convergence.

The sequence $g_\varepsilon$ Γ-converges to $g$ in the strong and weak sense, and so the condition a) of Proposition 3 in Section 2 is satisfied. Since $S \times Q$ is bounded, the operator $G$ have compact resolvent in $L^2(S \times Q)$ and item b) holds true as well. Again, by the Rellich-Kondrachov Theorem, but now combined with Lemma 1, ensure the validity of item c). By applying Proposition 3 we conclude the proof of Theorem 4.

6 A different renormalization

In this section we perform a different renormalization of the quadratic forms $\tilde{\mathcal{A}}^{\alpha,c}(v)$ and show, again via Γ-convergence and under additional conditions, that the same effective operator is reached in the limit $\varepsilon \to 0$. We underline that the renormalization ahead would be the first choice for the magnetic reduction of dimension, since it takes into account the presence of the magnetic field in the cross section, in contrast with the renormalization we took in previous sections.
First we have a closer look at the term $\int_{S \times Q} |\bar{\partial}_y v|^2 ds dy$ that appears in the quadratic form $\tilde{g}_\epsilon^{\alpha, \epsilon}(v)$. More precisely,

$$
\int_{S \times Q} \left( \left| (-i \partial_{y_2} - \tilde{A}_2^\epsilon(s, y)) u \right|^2 + \left| (-i \partial_{y_3} - \tilde{A}_3^\epsilon(s, y)) u \right|^2 \right) ds dy.
$$

Note that in $\tilde{g}_\epsilon^{\alpha, \epsilon}(v)$ this expression is multiplied by $\epsilon^{-2}$.

Consider the family of operators

$$
T_\epsilon^s u := \left[ (-i \partial_{y_2} - \tilde{A}_2^\epsilon(s, y))^2 + (-i \partial_{y_3} - \tilde{A}_3^\epsilon(s, y))^2 \right] u,
$$

$\text{dom } T_\epsilon^s = \mathcal{H}^2(Q) \cap \mathcal{H}^1_0(Q)$, and the operator

$$
Tu := [(-i \partial_{y_2})^2 + (-i \partial_{y_3})^2] u, \quad \text{dom } T = \mathcal{H}^2(Q) \cap \mathcal{H}^1_0(Q).
$$

$T_\epsilon^s$ and $T$ are positive self-adjoint operators. Given $\xi > 0$, we have $-\xi \in \rho(T_\epsilon^s)$ and $\xi \in \rho(T)$, i.e., $-\xi$ belongs to resolvent set these operators.

**Theorem 5.** There are $\epsilon_0 > 0$ and a number $E > 0$ so that

$$
\left\| (T_\epsilon^s + \xi I)^{-1} - (T + \xi I)^{-1} \right\| \leq E \epsilon,
$$

for all $\epsilon < \epsilon_0$, all $\xi > 0$ and all $s \in S$.

**Proof.** Consider the family of quadratic forms

$$
t_\epsilon^s(u) := \int_Q \left( \left| (-i \partial_{y_2} - \tilde{A}_2^\epsilon(s, y)) u \right|^2 + \left| (-i \partial_{y_3} - \tilde{A}_3^\epsilon(s, y)) u \right|^2 \right) dy,
$$

$\text{dom } t_\epsilon^s = \mathcal{H}^1_0(Q)$, and

$$
t(u) := \int_Q |\nabla u|^2 dy, \quad \text{dom } t = \mathcal{H}^1_0(Q),
$$

associated with the operators $T_\epsilon^s$ and $T$, respectively.

Given $\xi > 0$, we have

$$(t_\epsilon^s + \xi)(u) \geq \xi \|u\|^2 \quad \text{and} \quad (t + \xi)(u) \geq \xi \|u\|^2, \quad \forall u \in \mathcal{H}^1_0(Q), \quad \forall s \in S.$$

From the definitions of $\tilde{A}_2^\epsilon$ and $\tilde{A}_3^\epsilon$, it follows that there exist numbers $\tilde{E}_1, \tilde{E}_2 > 0$ so that

$$
|\tilde{A}_2^\epsilon(s, y)| \leq \tilde{E}_1 \epsilon \quad \text{and} \quad |\tilde{A}_3^\epsilon(s, y)| \leq \tilde{E}_2 \epsilon, \quad \forall (s, y) \in S \times Q.
$$
Therefore, there exist $E_1$, $E_2 > 0$ so that
\[
| ( t_s^* + \xi )( u ) - ( t + \xi )( u ) |
= \left| \int_Q \left( i \tilde{A}_3 \vec{u} \partial y_2 u - i \tilde{A}_2 u \partial y_2 \vec{u} + ( \tilde{A}_2 )^2 | u |^2 + i \tilde{A}_3 u \partial y_3 u - i \tilde{A}_3 u \partial y_3 \vec{u} + ( \tilde{A}_3 )^2 | u |^2 \right) dy \right|
\leq E_1 \varepsilon \left[ \int_Q ( | \vec{u} || \partial y_2 | u | + | u || \partial y_2 | \vec{u} | + | \vec{u} || \partial y_3 | u | + | u || \partial y_3 | \vec{u} | ) dy \right] + E_2 \varepsilon^2 \int_Q | u |^2 dy
\leq E_1 \varepsilon \left[ \left( \int_Q | \vec{u} |^2 dy \right)^{1/2} \left( \int_Q | \partial y_2 | u |^2 dy \right)^{1/2} + \left( \int_Q | u |^2 dy \right)^{1/2} \left( \int_Q | \partial y_3 | \vec{u} |^2 dy \right)^{1/2} \right]
+ E_2 \varepsilon^2 \int_Q | u |^2 dy
= 2 E_1 \varepsilon \left[ \left( \int_Q | u |^2 dy \right)^{1/2} \left( \int_Q | \partial y_2 | u |^2 dy \right)^{1/2} + \left( \int_Q | u |^2 dy \right)^{1/2} \left( \int_Q | \partial y_3 | \vec{u} |^2 dy \right)^{1/2} \right]
+ E_2 \varepsilon^2 \int_Q | u |^2 dy
\leq 4 E_1 \varepsilon \left[ \int_Q | u |^2 dy \right]^{1/2} \left( \int_Q | \nabla u |^2 dy \right)^{1/2} + E_2 \varepsilon^2 \int_Q | u |^2 dy,
\]
for all $u \in \mathcal{H}_0^1( Q )$ and $s \in S$.

By Poincaré's inequality one has, for all $u \in \mathcal{H}_0^1( Q )$ and $s \in S$,
\[
| ( t_s^* + \xi )( u ) - ( t + \xi )( u ) | \leq E_3 \varepsilon \int_Q | \nabla u |^2 dy = E_3 \varepsilon t(u),
\]
and for some $E_3 > 0$. Now, the result follows by an application of Theorem 3.

We can estimate the first eigenvalue of $T$, that is, $\lambda_0$, by the Rayleigh quotient
\[
\lambda_0 = \inf_{u \neq 0} \frac{ t(u) }{ || u ||^2 },
\]
and, for each $s \in S$, it gives us the first eigenvalue of $T_s^*$, i.e.,
\[
\lambda_s( s ) := \inf_{u \neq 0} \frac{ t_s^* ( u ) }{ || u ||^2 }.
\]

We need information about the sequence of eigenvalues $\lambda_c(s)$; we have got the following result.

**Lemma 3.** As $\varepsilon \to 0$, $\lambda_c(s) \to \lambda_0$ uniformly in $S$.

**Proof.** Inequality (13), in the proof of the Theorem, implies that
\[
( 1 - C_3 \varepsilon ) \inf_{u \neq 0} \frac{ t(u) }{ || u ||^2 } \leq \inf_{u \neq 0} \frac{ t_s^* ( u ) }{ || u ||^2 } \leq ( 1 + C_3 \varepsilon ) \inf_{u \neq 0} \frac{ t(u) }{ || u ||^2 } \quad \forall s \in S,
\]
that is,
\[
( 1 - C_3 \varepsilon ) \lambda_0 \leq \lambda_c(s) \leq ( 1 + C_3 \varepsilon ) \lambda_0, \quad \forall s \in S.
\]
By taking $\varepsilon \to 0$, it is found that $\lambda_c(s) \to \lambda_0$ uniformly in $S$. 

\[18\]
As already mentioned, the goal of this section is to perform a “magnetic renormalization” by subtracting 
\[ \int_{S \times Q} \frac{\lambda_e(s)}{\varepsilon^2} |v|^2 \, ds \, dv \]
from \( \tilde{g}_e(v) \), and then we try to find additional conditions so that it would give a well-defined effective operator as \( \varepsilon \to 0 \). Thus, we pass to study a new sequence of quadratic forms

\[
l_\varepsilon(v) := \int_{S \times Q} \left( \frac{1}{\beta^2} |\tilde{\partial}_s v - (\nabla_y v, R_y)(\tau + \alpha')(s)|^2 \right) \, ds \, dy \\
+ \frac{1}{\varepsilon^2} \int_{S \times Q} \left( |\tilde{\partial}_y v|^2 - \lambda_e(s) |v|^2 \right) \, ds \, dy - \int_{S \times Q} \frac{1}{\beta^2} \frac{k^2(s)}{4} |v|^2 \, ds \, dy \\
+ c \int_{S \times Q} |v|^2 \, ds \, dy,
\]

dom \( l_\varepsilon = H^1_0(S \times Q) \), and \( l_\varepsilon(v) = +\infty \) for \( v \in L^2(S \times Q) \setminus H^1_0(S \times Q) \). We denote by \( L_\varepsilon \) the self-adjoint operator associated with \( l_\varepsilon \).

By the very definition of \( \lambda_e(s) \), for each \( v \in H^1_0(S \times Q) \), one has

\[
\int_Q \left( |\tilde{\partial}_y v(s,y)|^2 - \lambda_e(s) |v(s,y)|^2 \right) \, dy \geq 0, \quad \text{a.e.} [s],
\]
and we see that the quadratic forms \( l_\varepsilon \) are positive.

For each \( s \in S \), fix a normalized eigenfunction \( u_\varepsilon(s,y) \) corresponding to \( \lambda_e(s) \). By Theorem \ref{thm5}, we conclude that, for each \( s \in S \),

\[
u_\varepsilon(s,y) \to u_0(y) \quad \text{and} \quad \nabla_y u_\varepsilon(s,y) \to \nabla_y u_0(y) \quad \text{in} \quad L^2(Q).
\]

Such convergences can be properly extended, i.e., we also have

\[
w(s)u_\varepsilon(s,y) \to w(s)u_0(y) \quad \text{and} \quad w(s)\nabla_y u_\varepsilon(s,y) \to w(s)\nabla_y u_0(y) \quad \text{in} \quad L^2(S \times Q),
\]

for all function \( w \in L^2(S) \).

The first condition we require is that

\[
w(s)u_\varepsilon(s,y) \in H^1_0(S \times Q), \quad \text{for all} \quad w \in H^1(S).
\]

Given \( w \in H^1(S) \), we also will need some information about the sequence \( w(\partial u_\varepsilon/\partial s) \). The first convergence in (17) implies

\[
w \frac{\partial u_\varepsilon}{\partial s} \to 0 \quad \text{in} \quad L^2(S \times Q).
\]

However, we are going to add the hypothesis of strong convergence

\[
w \frac{\partial u_\varepsilon}{\partial s} \to 0 \quad \text{in} \quad L^2(S \times Q), \quad \text{(19)}
\]

for all function \( w \in H^1(S) \). We have then the following result.

**Theorem 6.** Under the conditions (18) and (19), the sequence of operators \( L_\varepsilon \) converges to \( G \) in the norm resolvent sense as \( \varepsilon \to 0 \).
Recall that $G$ is the operator associated with the quadratic form $S$. The proof of this theorem is very similar to that of Theorem 4 after taking into account some observations. As before, one shows that the sequence $l_ε$ $Γ$-converges to $g$ in the strong sense. We have the following lemmas.

**Lemma 4.** If $v_ε → v$ in $L^2(S × Q)$ and $(l_ε(v_ε))_ε$ is a bounded sequence in $L^2(S × Q)$, then $(∂_sv_ε)_ε$ and $(∇_yv_ε)_ε$ are bounded sequences in $L^2(S × Q)$. Furthermore, $∂_sv_ε → ∂_sv, ∇_yv_ε → ∇_yv$ in $L^2(S × Q)$ and $v ∈ H^1_0(S × Q)$.

**Lemma 5.** Let $v_ε → v$ in $L^2(S × Q)$ so that there exists $\lim_{ε→0} l_ε(v_ε) < ∞$. Then, we can write $v(s, y) = w(s)u_0(y)$ with $w ∈ H^1(S)$.

Taking also into account Lemma 3, the inequality (19), the proofs of Lemmas 4 and 5 are similar to the proofs of Lemmas 1 and 2 respectively, and so they will not be repeated here.

**Proof of Theorem 6.** First we need to show that given $v ∈ L^2(S × Q)$ and $v_ε → v$ in $L^2(S × Q)$ we have $\liminf_{ε→0} l_ε(v_ε) ≥ l(v)$. But this step is similar to the corresponding one in the proof of Theorem 4. Just take into consideration inequality (19) and Lemmas 4 and 5.

Now we are going to show that for each $v ∈ L^2(S × Q)$ there exists a sequence $v_ε → v$ in $L^2(S × Q)$ so that $\lim_{ε→0} l_ε(v_ε) = g(v)$. First consider the case $v = wu_0$ with $w ∈ H^1(S)$. For each $ε > 0$, write $v_ε(s, y) = w(s)u_ε(s, y)$. We have $v_ε → wu_0$ in $L^2(S × Q)$. Under (18) and (19), it follows that

$$\lim_{ε→0} l_ε(v_ε) = \lim_{ε→0} \int_{S×Q} \left\{ \frac{1}{β_ε^2} \left| ∂_sv_ε - (\nabla_yv_ε, R_y)(τ + α')(s) \right|^2 \right. - \frac{1}{β_ε^2} \frac{k^2(s)}{4} |v_ε|^2 \left. + c|v_ε|^2 \right\} dyds$$

$$= \int_{S×Q} \left\{ \left| (-i∂_s - \langle A(r(s)), T(s) \rangle)v - ∫\nabla_yv, R_y)(τ + α')(s) \right|^2 + \left( c - \frac{k^2(s)}{4} \right) |v|^2 \right\} dyds$$

$$= g(ω) = g(wu_0).$$

If $v ∈ L^2(S × Q) \setminus \{wu_0 : w ∈ H^1(S)\}$ we have $g(v) = ∞$. Let $v_ε$ be a sequence so that $v_ε → v$ in $L^2(S × Q)$. In this case, $\lim_{ε→0} l_ε(v_ε) = ∞$. In fact, we suppose $\lim_{ε→0} l_ε(v_ε) < ∞$. By Lemmas 1 and 2 we should have $v = wu_0$, with $w ∈ H^1(S)$, which does not occur. Therefore, $\lim_{ε→0} l_ε(v_ε) = ∞ = g(v)$.

We have shown above that the sequence $l_ε$ $Γ$-converges to $g$ in the strong sense (and, consequently, in the weak sense). By applying Proposition 4 of Section 2 we conclude the proof of theorem.
