Received: December 9, 2013; Revised: October 25, 2014; Accepted: November 10, 2014

Background: Recently, investigations have indicated that caring of a chronically ill family member strongly influences the health status and the quality of life (QOL) of the caregiving family members.

Objectives: The purpose of this study was to examine the relationship between health-related QOL of veterans with chronic spinal cord injury and their caregiving spouses.

Patients and Methods: We designed a cross-sectional study including two groups; veterans with chronic spinal cord injury and their caregiving wives who were living in the city of Mashhad, Iran. The patients with spinal cord injury were veterans from the Iran-Iraq war (1980-1988). All the participants filled out the short form 36 (SF-36) health survey questionnaire. A Pearson correlation coefficient was calculated for the scales of the two groups.

Results: The mean age and standard deviation of veterans and their spouses were 48.5 ± 5.9 and 44.8 ± 7.2, respectively and their number of children ranged between 0-6. Our data analysis showed that there was a significant difference between the two groups in some domains of the SF-36, including PF, MH, PCS, MCS, BP and GH (P < 0.05), but there was no significant difference in RP, VT, SF and RE between the two groups.

Conclusions: The results indicate that a decrease in health status level of veterans, physically and mentally, can affect the health-related QOL of their caregiving spouses.

Keywords: Spinal Cord Injury; Veterans; Caregiving; Quality of Life; Iran

1. Background
Quality of life (QOL) is defined as a multidimensional construct which includes health, functional, psychological, emotional and spiritual aspects, as well as socioeconomic and family status [1-4]. Many recent investigations have indicated that caring for a chronically ill family member strongly impacts the health status and QOL of the caregiving family member [1-8]; some factors such as education about patients with spinal cord injury and their psychological status affects their caregivers’ health status [9-13]. Spinal cord injury affects different aspects of a patient’s life, and hence, causes different physical and mental changes associated with the individual’s situation [14, 15]. In chronic diseases and disabilities, these conditions affect not only the QOL of those people with the morbidities, but also the family members who take care of them for a long time [1-8]. Some studies have claimed that there is a direct relationship between health and QOL of individuals with chronic disabilities and their caregivers [16, 17]. The main concern is that the physical and emotional health of family caregivers may impact the health status and welfare of their patients [1-6].

2. Objectives
The purpose of this study was to examine the relationship between health-related QOL in veterans with chronic spinal cord injury and their caregiving spouses.

3. Patients and Methods
We designed a cross-sectional study with two groups of people; veterans with chronic spinal cord injury and their caregiving wives. The study was performed at the Orthopedic Research Center, Mashhad University of Medical Sciences, Mashhad, Iran, in 2011. It was approved by the Committee of Ethical Affairs in Research of our institution. Fifty male veterans with long-standing war-related spinal cord injuries from the Iran-Iraq war (1980-88) and their wives, who were living in the city of Mashhad, Iran, were invited to participate in this survey. A total of 37 (74%) couples participated in this study in 2012. Before conducting the survey, all the individuals were informed about the nature of the study, and then, they all signed a consent form agreeing to participate in the study. Afterwards, we took the medical history of all the veterans and their caregiving wives and they were asked to fill out the related questioners. Although all the participants were literate, those who had difficulties with writing received assistance by a nurse to fill out the forms. We collected demographic data and medical his-
of the couples and conducted a physical examination on them.

3.1. Measurements

The medical outcomes study short form 36 (SF-36) was provided to the veterans and their spouses. The SF-36 health survey, which is called health-related QOL assesses mental and physical health in eight aspects: physical function (PF), social functioning (SF), role physical (RP), role emotional (RE), mental health (MH), vitality (VT), bodily pain (BP), and general health (GH). In addition to these items, it includes two general measures involved with physical and mental component summaries (PCS and MCS, respectively). Since its introduction in 1996, SF-36 has been used in numerous studies for evaluating the health status, QOL and clinical outcomes of treatment and health care around the world (18). The psychometric properties of SF-36 have been tested for many musculoskeletal disorders including spinal cord injury, assessing the patients and their caregivers (19-22). SF-36 has also been studied in terms of validity and reliability in many languages and cultures (23-25). The Persian translation of SF-36 has been reported as valid and reliable among the Farsi-speaking population in 2005 (26).

3.2. Statistical Analysis

To carry out a comparison between various dimensions of the SF-36 questionnaire among veterans and their caregiving wives; the Pearson correlation was applied. A P value of less than 0.05 was considered significant in all of our data analyses. We used SPSS software version 11.5, (SPSS, Inc., Chicago, IL, USA), for data analysis.

4. Results

4.1. Demographic Data of the Participants

A total of 37 couples participated in the study including 37 patients with spinal cord injury and their 37 spouses. The mean age of the veterans was 48.5 ± 5.9 and their wives 44.8 ± 7.2. The range of the number of children was from 0 to 6 with an average of 2.25 ± 1; 14 (37.8%) veterans had been married before and 23 (62.2%) had got married after their spinal cord injuries sustained. The education status in veterans and their spouses was high school and diploma (45.9%) and higher education levels (16.2%). Regarding their employment situations, 29 (78.4%) of the veterans and 33 (89.2%) of their caregiving wives were unemployed, meaning that less than 25% of both group were employed (Table 1).

4.2. The Study Short Form 36 Scores

The mean and SD of MCS in the veterans with spinal cord injury was 50.8 (11.8) and in their spouses 37.7 ± 14.5. However, the mean and SD for PCS were 31.7 ± 14.1 and 41.2 ± 13.3, respectively. These results are summarized in Table 1.

| Table 1. Demographic Variables of the Cohort Groups a,b |
|--------------------------------------------------------|
| Characteristics                                      | Values                      |
| Caregiving wives                                      |                             |

4.3. Comparison of Health-Related Quality of Life in Veterans With Spinal Cord Injury and Their Spouses

When the two groups were compared, data analysis demonstrated that there was a significant difference (P < 0.01) in some domains of the SF-36 health survey, including PF, MH, BP, GH, PCS and MCS, between veterans with spinal cord injury and their caregiving spouses. However, there was no significant difference between RE, VT and SF (Table 2 and Figure 1).

b Statistically significant at the 0.01 level.
c Statistically significant at the 0.05 level.
4.4. Correlation of the Quality of Life Between Veterans With Spinal Cord Injury and Their Caregiving Wives

Comparison of different items of the SF-36 between the veterans with spinal cord injury and their spouses illustrated that there was a significant positive correlation between PF of the caregiving wives and RE (P = 0.045) and MH (P = 0.046) of the veterans. The same results were observed between VT of the spouses and PF (P = 0.022) of the veterans. In addition, there was a significant negative correlation between SF of the spouses and BP of the veterans (P = 0.032), as well as a significant negative correlation between RE of the spouses and GH of the veterans (P = 0.041). There was also a significant positive correlation between MH of the spouses and PF of the veterans (P = 0.038) as well as a significant negative correlation between MH of the spouses and GH of the veterans (P = 0.042) (Table 3).

Table 3. Correlation of the Quality of Life Between the Veteran and Their Spouses a

5. Discussion

The influence of caregiving to patients with chronic spinal cord injury has not been well documented yet. Furthermore, there are a few reports on the relationship between the caregivers’ health status and the QOL of patients with chronic diseases; thus, the bilateral effects of health status of patients with chronic spinal cord injury and their caregiving spouses need to be investigated (3, 27, 28). Spinal cord injury can affect the health status and QOL both physically and emotionally. Therefore, in this study, we compared the health-related QOL between patients with chronic spinal cord injury and their caregiving spouses using the SF-36 health survey form. Spinal cord injury can cause important changes to physical, psychological, emotional and social health of a person. In fact, some of these physical changes involve sensory dysfunction and disability in bladder, bowel and sexual function (29). Evidences demonstrated that primary caregivers of a patient with chronic spinal cord injury will have a lower level of health-related QOL (7). Similar to these findings were achieved in our study, confirming the burden and effect of caregiving and nursing for husbands with chronic spinal cord injury on the health-related QOL of their spouses. The comparison of the averages of SF-36 domains indicated that PF in caregiving spouses was significantly higher than veterans; conversely, the MH scale was in a higher level in veterans compared to their wives ($p = 0.002$). These findings were similar to those of Setsuko et al. who examined health-related QOL among patients with chronic peritoneal dialysis and their caregiving family members in Japan. This study showed that a chronic illness affected the emotions and mental health status of caregiving family members more than those of the patients (30). In our survey, PCS was a competent of SF-36, which was significantly lower in veterans ($p = 0.004$) than their caregiving spouses. In fact, spinal cord injury can greatly reduce the physical health level; therefore, a reduction of QOL in veterans would be expectable. BP was another dimension of the physical health level; therefore, a reduction of QOL in veterans was a significant mutual correlation in comparison of some items of SF-36 in the two groups, and finally, there was a significant mutual correlation in comparison of the QOL of veterans and their loved families. Generally, the results confirmed that a lower health status level, physically and mentally, can affect the health-related QOL of their caregiving spouses.

Acknowledgements

This research was conducted in cooperation with veterans with spinal cord injury and their spouses in Khorasan Razavi province ( Mashhad, Iran). Without their assistance, we would not be able to do this study. We should thank the veterans and their spouses for their patience and cooperation. In addition, we would like to thank Mashhad University of Medical Sciences for their help to continue the survey.
