Abstract

We study $n$-string scattering amplitudes in three-dimensional Anti-de Sitter space ($\text{AdS}_3$). We focus our attention on the processes in which the winding number conservation is violated maximally; that is, those processes in which it is violated in $n - 2$ units. A worldsheet conformal field theory calculation leads us to confirm a previous conjecture about the functional form of these observables.
1 Introduction

String theory in AdS$_3$ has served as a model to explore AdS/CFT correspondence beyond the supergravity approximation. What makes this possible is that in the three-dimensional case one has access to the worldsheet conformal field theory formulation in terms of the $SL(2, \mathbb{R})$ Wess-Zumino-Witten model (WZW) [1][2], and thus several observables of the theory, like three-point functions, can be solved exactly. This, together with the existence of a non-renormalization argument [3], has led the authors of [4][5][6] to perform explicit checks of the matching between bulk and boundary correlators at the string theory level (see also [7][8][9][10]). The agreement found was exact, and this represents one of the few examples in which one sees the bulk-boundary correspondence to hold beyond the field theory approximation.

Besides its correlators being solvable, string theory in AdS$_3$ presents several interesting aspects. In particular, its spectrum is very rich and exhibits intriguing properties. As observed in [1][2], in order to completely parameterize the spectrum of string theory in AdS$_3$, it is necessary to consider spectrally flowed sectors of the space of representation of the $sl(2)_k$ affine algebra. These sectors are labeled by an integer number $\omega$, whose physical interpretation is that of specifying the winding number of the string states. This winding number is a dynamical degree of freedom associated to the presence of the $B$-field in the background. Not being a topological quantity, this winding number can in principle be violated if a string scattering process takes place. However, such a violation is not totally arbitrary, and it happens to be bounded from above following a curious pattern: In a scattering process that involves $n$ strings, the total winding number $\Delta \omega = \sum_{i=1}^{n} \omega_i$ is restricted to obey the bound $|\Delta \omega| \leq n - 2$; see [2]. In this paper, we will focus on the case where this bound is saturated; namely we will analyze $n$-string interaction processes satisfying $|\Delta \omega| = n - 2$.

$n$-string amplitudes in AdS$_3$ space admit to be written in terms of Liouville theory correlation functions. This was explicitly shown in [11] for the case in which the winding number conservation is violated up to $n - 3$ units (i.e. $|\Delta \omega| < n - 2$.) A natural expression for the maximal case $|\Delta \omega| = n - 2$ was also proposed in [11] following an educated guess; however, in such special case the proof in [11], based on the analysis of modular differential equations [12][13], does not hold because the corresponding Liouville $n$-point correlators do not generically involve degenerate primaries (see also [14]). Therefore, when the winding number conservation is violated maximally, the formula in [11] that expresses $n$-string amplitudes in AdS$_3$ in terms
of $n$-point Liouville correlators remains a conjecture. The aim of this paper is to show that a free field computation in the worldsheet conformal field theory actually confirms that formula. Proving so, amounts to review the free field formalism introduced in references \cite{15, 16}, which is particularly useful to compute worldsheet correlation functions that violate the winding number conservation. The formalism is based on the Dotsenko conjugate representations introduced for the $SU(2)$ case in references \cite{17, 18} and extended to the $SL(2, \mathbb{R})$ case in references \cite{15, 16, 19}.

\section{Worldsheet conformal field theory in AdS$_3$}

Let us begin by briefly reviewing string theory in AdS$_3$. The theory is described by the level-$k$ $SL(2, \mathbb{R})$ WZW model, where $k$ is given by $k = l^2/\alpha'$, being $-l^{-2}$ the curvature of AdS$_3$. The string spectrum is given by a subset of the direct sum of unitary $SL(2, \mathbb{R})$ representations \cite{1}; while discrete representations correspond to short string states, the continuous series correspond to long string states, for which we do have an S-matrix interpretation. The string scattering amplitudes in AdS$_3$ are then given by integrating the $SL(2, \mathbb{R})$ WZW correlation functions over the worldsheet \cite{2}.

Correlation functions in the $SL(2, \mathbb{R})$ WZW model are defined by analytic continuation of correlation functions in the model formulated on $\mathbb{H}^3_+$, which corresponds to Euclidean AdS$_3$. It is convenient to start by discussing the model on $\mathbb{H}^3_+$ first. More specifically, we should actually start by considering the model on $\mathbb{H}^3_+/U(1) \times \mathbb{R}$, which, as suggested in \cite{1} and shown in \cite{15, 16, 19}, is the adequate construction to describe winding string states. To describe the model on $\mathbb{H}^3_+/U(1) \times \mathbb{R}$, one may use Wakimoto free field representation \cite{20} with the addition of extra fields: First, one adds a spacelike $U(1)$ free boson $X(z)$ to realize the coset $\mathbb{H}^3_+/U(1)$, as in \cite{21, 22}, and then adds an extra timelike free boson $T(z)$ to represent the $\mathbb{R}$ time direction. The piece $\mathbb{H}^3_+$ is realized by the standard Wakimoto representation, which consists of a $\beta$-$\gamma$ ghost system and a boson $\phi$ with background charge.

Being described by the WZW model, the theory exhibits $SL(2, \mathbb{R})_k \times SL(2, \mathbb{R})_k$ affine Kac-Moody symmetry, whose holomorphic part can be expressed in terms of the following operator
product expansion (OPE)

\[ J^3(z)J^\pm(w) \simeq \pm \frac{J^\pm(w)}{(z-w)} + \mathcal{O}(1) \quad (1) \]

\[ J^+(z)J^-(w) \simeq \frac{k}{(z-w)^2} + 2\frac{J^3(w)}{(z-w)} + \mathcal{O}(1) \quad (2) \]

\[ J^3(z)J^3(w) \simeq \frac{-k/2}{(z-w)^2} + \mathcal{O}(1) \quad (3) \]

where the \( \mathcal{O}(1) \) stand for regular terms. Analogous OPE holds for the anti-holomorphic piece.

The double poles in the OPE above encode the contribution of the central element of the \( sl(2)_k \) affine algebra.

Using the free field representation mentioned above, the \( sl(2)_k \) currents may be realized as follows

\[ J^+(z) = \beta(z)e^{i\sqrt{2k}(X(z)+T(z))}, \]

\[ J^3(z) = -\beta(z)\gamma(z) - \sqrt{\frac{k-2}{2}}\partial\phi(z) - i\sqrt{\frac{k}{2}}\partial X(z) - i\sqrt{\frac{k}{2}}\partial T(z), \]

\[ J^-(z) = (\beta(z)\gamma^2(z) + \sqrt{2k-4}\gamma(z)\partial\phi(z) + k\partial\gamma(z)) e^{-i\sqrt{2k}(X(z)+T(z))}. \]

with the free field propagators

\[ \langle \phi(z)\phi(w) \rangle = \langle X(z)X(w) \rangle = -\langle T(z)T(w) \rangle = -\log(z-w), \quad \langle \beta(z)\gamma(w) \rangle = \frac{1}{(z-w)}; \]

and analogously for the anti-holomorphic contributions.

The states of the theory are labeled by indices \( j \) and \( m \), as it is usual when classifying representations of \( SL(2, \mathbb{R}) \). It is also necessary to introduce an integer index \( \omega \) to specify which spectral flow sector of the \( sl(2)_k \) algebra the states are Kac-Moody primary with respect to. Then, we denote the states by kets \( |j, m, \omega\rangle \).

The vertex operators that create these states are

\[ \Phi^\omega_{j,m,\overline{m}}(z) = c_0 \gamma^{j-m}_z e^{i\sqrt{2k}j\phi(z)} e^{i\sqrt{2k}mX(z)} e^{i\sqrt{2k}(m+\frac{\omega}{2})T(z)} \times \text{h.c.} \]

where h.c. stands for Hermitian conjugate, which is actually a misnomer as it involves the contributions that depend on \( \overline{m} \). The factor \( c_0 \) is a normalization constant, independent of \( j \) and \( m \).
Operators (8) create the in-states from the \( SL(2, \mathbb{R}) \) invariant vacuum \(|0\rangle\); namely

\[
\lim_{z \to 0} \Phi^\omega_{j,m,\overline{m}}(z) |0\rangle = |j, m, \overline{m}, \omega\rangle \tag{9}
\]
as well as the out-states

\[
\langle j, m, \overline{m}, \omega = \lim_{z \to \infty} z^{2h_j^\omega} z^{2h_{\overline{m}}^\omega} \langle 0 | \Phi^\omega_{-1-j, m, \overline{m}}(z), \tag{10}
\]

where \( h_j^\omega \) is the conformal dimension of the operators,

\[
h_j^\omega = -\frac{j(j+1)}{k-2} - m\omega - \frac{k}{4} \omega^2. \tag{11}
\]

It is worth noticing that the formula for the conformal dimension remains unchanged under the Weyl reflection \( j \to -1-j \). That is, the states created by the operator \( \Phi^\pm_{j,m,\overline{m}} \) have the same conformal dimension than those created by \( \Phi^\omega_{j,m,\overline{m}} \).

Operators (8) have the following OPE with the \( sl(2)_k \) Kac-Moody currents

\[
J^3(z) \Phi^\omega_{j,m,\overline{m}}(w) \simeq \frac{(m + k\omega/2)}{(z-w)} \Phi^\omega_{j,m,\overline{m}}(w) + \mathcal{O}(1) \tag{12}
\]

\[
J^\pm(z) \Phi^\omega_{j,m,\overline{m}}(w) \simeq \frac{(\pm j - m)}{(z-w)^{1+\omega}} \Phi^\omega_{j,\pm 1, m}(w) + \mathcal{O}((z-w)\overline{\omega}) \tag{13}
\]

The theory also admits conjugate representations of the vertex operators. These are important ingredients in our discussion. Such conjugate representations are defined by operators

\[
\tilde{\Phi}^\omega_{j,m,\overline{m}}(z) = \frac{1}{Z_{j,m}} \beta^{j+m} e^{-\sqrt{k} \sqrt{|j+\frac{k}{2}|} \phi(z)} e^{i \sqrt{2} (m-\frac{k}{2}) X(z)} e^{i \sqrt{2} (m+\frac{k}{2}) \overline{X}(z)} \times \text{h.c.} \tag{14}
\]

which create conjugate in-states

\[
\lim_{z \to 0} \tilde{\Phi}^\omega_{j,m,\overline{m}}(z) |0\rangle = |j_n, m_n, \overline{m}_n, \omega_n\rangle. \tag{15}
\]

In (14) \( Z_{j,m}^{-1} \) stands for a normalization factor, which gets fixed once one requires the two-point function between an operator (8) and its conjugate (14) to be normalized to one; namely \( \langle j, m, \overline{m}, \omega | j, -m, -\overline{m}, -\omega \rangle \equiv 1 \). This yields

\[
Z_{j,m} = (-1)^{j+m} c_0 \Gamma(j + m + 1). \tag{16}
\]
Conjugate representation (14) was introduced in [19]. These operators can be thought of as a twisted version of the operators proposed in [21] to describe discrete states in the two-dimensional black hole background. Operators (14) create states in a conjugate representations $|j_n, m_n, \bar{m}_n, \omega_n \rangle$. This is analogous to the $SU(2)$ case studied in [17].

It is easy to verify that operators $\Phi^\omega_{j,m,\bar{m}}$ and $\tilde{\Phi}^\omega_{j,m,\bar{m}}$ create states with the same conformal dimension (11). Besides, one can also verify that (14) obeys the following OPE with the currents

$$J^3(z)\tilde{\Phi}^\omega_{j,m,\bar{m}}(w) \simeq \frac{(m + k\omega/2)}{(z - w)} \tilde{\Phi}^\omega_{j,m,\bar{m}}(w) + O(1)$$

(17)

$$J^{\pm}(z)\tilde{\Phi}^\omega_{j,m,\bar{m}}(w) \simeq \frac{(\mp 1 \mp j - m)}{(z - w)^{1\pm\omega}} \tilde{\Phi}^\omega_{j,m,\bar{m}}(w) + O((z - w)^{\mp\omega});$$

(18)

that is, conjugate operators $\tilde{\Phi}^\omega_{j,m,\bar{m}}$ have exactly the same properties that the Weyl-reflected operator $\Phi^{-1}_{-j,m,\bar{m}}$. In fact, as pointed out in [19], Weyl reflection can also be thought of as a conjugation operation associated to the zero-dimension field $\Phi^{-1}_{0,0,0}(z) = \gamma(z) e^{-\sqrt{\frac{2}{k}} \phi(z)} \times h.c.$

Important ingredients of the Coulomb gas realization that the free field approach leads to are the screening operators. These are given by

$$\tilde{\Phi}^{-1}_{1,\frac{1}{2},\frac{1}{2}}(z) = \beta(z) e^{-\sqrt{\frac{\pi}{2}} \phi(z)} \times h.c.$$  

(19)

These operators have conformal dimension one and regular OPE with the Kac-Moody currents.

Another special case of operators (14) is the conjugate representation of the identity operator. This is given by the zero-dimension field

$$\tilde{\Phi}^0_{0,0,0}(z) = \Phi^1_{-\frac{1}{2},-\frac{1}{2},-\frac{1}{2}}(z) = e^{-\sqrt{\frac{\pi}{2}} \phi(z)} e^{-i \sqrt{\pi} \chi(z)} \times h.c.$$  

(20)

Operator (20) was first introduced by Fateev and the brothers Zamolodchikov in their renowned FZZ unpublished paper [23], and in reference [2] it was dubbed spectral flow operator. Representation (20) is important to define the charge asymmetry conditions; see [17] for the details.

### 3 String scattering amplitudes in AdS3

In references [15, 16, 19], conjugate representations were considered to describe string scattering amplitudes in AdS3 in the case where the winding number is taken into account. Based on an
adaptation of Dotsenko works \cite{17, 18}, a prescription was proposed to calculate the correlators on $\mathbb{H}^3_1 / U(1) \times \mathbb{R}$. According to such prescription, the string scattering amplitudes of $n$-strings in AdS$_3$ are obtained by integrating over the worldsheet the following correlation function

$$X_n^{\Delta \omega} = \langle j_1, m_1, \overline{m}_1, \omega_1 | \prod_{i=2}^{p} \Phi_{j_i, m_i, \overline{m}_i} (z_i) \prod_{l=p+1}^{n-1} \tilde{\Phi}_{j_l, m_l, \overline{m}_l} (z_l) | j_n, m_n, \overline{m}_n, \omega_n \rangle$$ \hspace{1cm} (21)

where $\Delta \omega = \sum_{i=1}^{n} \omega_i = p + 1 - n$ (notice that $p \geq 1$). That is, the tree-level string amplitude is given by

$$A_{\text{string}}^{\Delta \omega} = \int \prod_{i=3}^{n-1} d^2 z_i \ X_n^{\Delta \omega},$$ \hspace{1cm} (22)

integrating over $n - 3$ vertex insertions on the sphere.

Here we are concerned with the amplitudes of processes in which the total winding number is violated in $n - 2$ units; namely, we will consider correlation functions

$$X_n^{2-n} = \langle j_1, m_1, \overline{m}_1, \omega_1 | \prod_{i=2}^{n-1} \tilde{\Phi}_{j_i, m_i, \overline{m}_i} (z_i) | j_n, m_n, \overline{m}_n, \omega_n \rangle.$$ \hspace{1cm} (23)

For this correlator not to vanish, it is necessary to insert a precise amount $s$ of screening operators \cite{19}. $s$ is determined by the charge asymmetry condition corresponding to the field $\phi(z)$, which yields $s = -1 - \sum_{i=1}^{n} j_i - (n - 2)k/2$. On the other hand, the charge asymmetry conditions corresponding to the fields $X(z)$ and $T(z)$ demand $\sum_{i=1}^{n} m_i = \sum_{i=1}^{n} \overline{m}_i = (n - 2)k/2$ and $\sum_{i=1}^{n} \omega_i = 2 - n$.

For further purpose it will be necessary to renormalize the vertex operators $\tilde{\Phi}_{j_i, m_i, \overline{m}_i}$ of the $n - 2$ intermediate states, $i = 2, 3, 4, ... n - 1$. To do so, first we rewrite $Z_{j, \overline{m}}$ as follows

$$Z_{j, \overline{m}} = (-1)^{j+m} c_0 \Gamma(j + \overline{m} + 1) = \lim_{\epsilon \to 0} c_0 \ Z_{j, \overline{m}}^{(e)} \ \text{with} \ Z_{j, \overline{m}}^{(e)} = \frac{\Gamma(\epsilon)}{\Gamma(\epsilon - j - \overline{m})},$$

and then introduce a regularization factor to extract the divergence by renormalizing $c_0$; namely

$$\prod_{l=2}^{n-1} \frac{1}{Z_{j_l, \overline{m}_l}} = \lim_{\epsilon \to 0} \epsilon^{2-n} (c_0/\epsilon)^{2-n} \prod_{l=2}^{n-1} \frac{1}{Z_{j_l, \overline{m}_l}^{(e)}} = c^{2-n} \prod_{l=2}^{n-1} (-1)^{-j_l-m_l} \frac{\Gamma(-j_l-\overline{m}_l)}{\Gamma(1+j_l+m_l)}.$$ \hspace{1cm} (24)

The amplitudes of a scattering process of $n$ strings in which the winding number conservation is violated in $n - 2$ units is then given by integrating the correlation function

$$X_n^{2-n} = \frac{(1-s)2^{j_n-m_n-\overline{m}_n} \Gamma(-s) c^{2-n} \prod_{l=2}^{n-1} (-1)^{-j_l-m_l} \Gamma(-j_l-\overline{m}_l)}{\Gamma(1+j_n+m_n) \Gamma(1+j_n+\overline{m}_n)} \int \prod_{r=1}^{s} d^2 y_r \langle \gamma_{(z_1)}^{-1-j_1-m_1} \prod_{l=2}^{n} \beta_{(z_l)}^{j_l+m_l} \prod_{r=1}^{s} \beta_{(y_r)}^{r} \rangle.$$\hspace{1cm} (25)
where the integrals over \( y_r \) come from the insertion of \( s \) screening operators, with \( s = -1 - \sum_{i=1}^{n} j_i - (n - 2)k/2 \); and where we set \( z_1 = \infty \), \( z_2 = 1 \), and \( z_n = 0 \).

Expanding the Wick contractions, and considering the free field propagators (31), one finds the integral expression

\[
X_n^{2-n} = e^{2-n} \sum_{i=1}^{n} \frac{1}{\Gamma(1 + j_i + m_i)} \prod_{i<j} (z_i - z_j)^{-2\alpha_i \alpha_j} \Gamma(-\alpha_i) \Gamma(-\alpha_j) \prod_{i=1}^{n-1} s_{i-1}^{n} |z_i - y_i|^{-2\alpha_i} |y_i - y_{i+1}|^{-2b^2},
\]

where we introduced the notation \( \alpha_i = b(j_i + 1 + b^{-2}/2) \) with \( b^{-2} = k - 2 \), and \( \beta_{ij} = k/2 - m_i + m_j - k\omega_i\omega_j/2 - m_i\omega_j - m_j\omega_i \), and analogously for \( \overline{\beta}_{ij} \) changing \( m_i \) and \( \omega_i \) for \( \overline{m}_i \) and \( \overline{\omega}_i \), respectively. Notice that, in terms of \( \alpha_i \), we have \( s = b^{-1} \sum_{i=1}^{n} \alpha_i + 1 + b^{-2} \).

In finding an expression like (24), the rapid way of dealing with the contraction of the \( \beta\gamma \) system is that of first assuming the case of \( j_1 - m_1 \) being a positive integer and then extending the resulting expressions. Also, it was used in (24) that the product of the multiplicity factor coming from the Wick contraction of the \( \beta\gamma \) contribution and the normalization of the \( n^{th} \) vertex can be rewritten as

\[
\frac{\Gamma(-j_1 - m_1) \Gamma(-j_1 - \overline{m}_1)}{\Gamma(1 + j_1 + m_1) \Gamma(1 + j_1 + \overline{m}_1)} = \frac{\Gamma(-j_n - \overline{m}_n)}{\Gamma(1 + j_n + m_n) \Gamma(1 + j_n + \overline{m}_n)} (-1)^{\sum_{i=1}^{n} \alpha_i + 1 + b^{-2}}.
\]

The \( z_i \)-dependent factor in the first line of (24) comes from the Wick contraction of the fields \( X(z) \) and \( T(z) \). In the second line of (24), on the other hand, one already sees the \( n \)-point Liouville correlation function appearing. In fact, Liouville correlation functions of primary operators \( V_{\alpha_i}(z_i) = e^{2\alpha_i \phi(z_i)} \) are given by

\[
\langle \prod_{i=1}^{n} V_{\alpha_i}(z_i) \rangle_L = \int \mathcal{D} \varphi \ e^{-\frac{1}{2b} \int d^2 w ((\partial \varphi)^2 + (b+1/b)R \varphi + 4\pi e^{2\varphi})} \prod_{i=1}^{n} e^{2\alpha_i \varphi(z_i)} =
\]

\[
= \frac{\Gamma(-s)}{b^{n-1}} \prod_{i<j} (z_i - z_j)^{-2\alpha_i \alpha_j} \prod_{i=1}^{n} s_{i-1}^{n} |z_i - y_i|^{-2\alpha_i} |y_i - y_{i+1}|^{-2b^2}
\]

with \( s = -b^{-1} \sum_{i=1}^{n} \alpha_i + 1 + b^{-2} \). This means that, after absorbing an irrelevant factor, we can write correlation functions (23) as follows

\[
X_n^{2-n} = e^{2-n} \sum_{i=1}^{n} \frac{1}{\Gamma(1 + j_i + m_i)} \prod_{i<j} (z_i - z_j)^{-2\alpha_i \alpha_j} \prod_{i=1}^{n} \langle \prod_{i=1}^{n} V_{\alpha_i}(z_i) \rangle_L,
\]

(25)
recalling $\beta_l = k/2 - m_l - m_l - k \omega_1/2 - m_l \omega_1 - m_l \omega_1$, $\alpha_i = b(j_i + 1 + b^{-2}/2)$, and $b^{-2} = k - 2$.

4 Conclusions

Expression (25) is exactly the expression conjectured in [11] for the case $|\Delta \omega| = n - 2$, and this is what we wanted to prove. The worldsheet conformal field theory calculation in terms of free fields actually confirms that formula. It is worth pointing out that resorting to the prescription of [15, 16, 19] in terms of conjugate representations was crucial to find (25); a free field calculation in terms of the standard Wakimoto representation for the vertices (c.f. [22]) would never lead to such a direct computation, in particular because it is not clear in that case how to implement the winding number violation. Therefore, the result obtained here can be interpreted as a non-trivial test passed by the prescription of [15, 16, 19], which seems to be powerful enough to yield an expression like (25) even in a case in which the modular differential equations are not at hand. Of course, even when convincing, a computation based on a free field realization can hardly be considered a rigorous proof; in particular, it strongly relies on analytic continuation of the integral formulas involved. However, it is still interesting that formula (25) is confirmed by these means. It has already been argued in [11] that free field computations in the FZZ dual theory done by Fateev in an unpublished paper [24] gave further evidence in favor of the validity of (25).

This work was supported by ANPCyT, CONICET, and UBA.

5 Addendum

Let us revisit the computation of maximally winding violating string amplitudes in three-dimensional Anti-de Sitter space discussed above. Here, we give an alternative derivation of these observables. This derivation, the simplest to the best of our knowledge, follows from identities between spectrally flowed representations of $\hat{sl}(2)_k$ Kac-Moody algebra and, in contrast to the one described above, it does not resort to conjugate representations with auxiliary fields, but it rather involves the standard Wakimoto free field representation.
The generators of the Kac-Moody $\hat{sl}(2)_k$ algebra satisfy the Lie products

$$[J^3_n, J^\pm_m] = \pm J^\pm_{n+m} , \quad [J^3_n, J^3_m] = \frac{k}{2} m \delta_{n+m,0} , \quad [J^+_n, J^-_m] = -2J^3_{n+m} + k n \delta_{n+m,0} .$$  \hfill (26)

with $a = 3, \pm$. These brackets, and its complex conjugate counterpart, are realized by defining the local currents

$$J^a(z) = \sum_{n \in \mathbb{Z}} J_n z^{-1-n} , \quad \bar{J}^a(\bar{z}) = \sum_{n \in \mathbb{Z}} \bar{J}_n \bar{z}^{-1-n}$$  \hfill (27)

and computing the operator product expansion (OPE) among them. A useful representation of these local currents has been given by Wakimoto \cite{20}, who proposed

$$J^+(z) = \beta(z) ,$$  \hfill (28)

$$J^3(z) = -\beta(z)\gamma(z) - \sqrt{\frac{k-2}{2}} \partial\phi(z) ,$$  \hfill (29)

$$J^-(z) = \beta(z)\gamma^2(z) + \sqrt{2k-4}\gamma(z)\partial\phi(z) + k\partial\gamma(z) .$$  \hfill (30)

with the free field propagators

$$\langle \phi(z)\phi(w) \rangle = -\log(z-w) , \quad \langle \beta(z)\gamma(w) \rangle = \frac{1}{(z-w)} ;$$  \hfill (31)

and analogously for the anti-holomorphic contributions.

Algebra \cite{20} is invariant under the spectral flow operation

$$J^3_n \to J^3_n + \frac{k}{2} \omega \delta_{n,0} , \quad J^\pm_n \to J^\pm_{n+\omega} .$$  \hfill (32)

This generates a whole family of new representations, usually denoted $C^\omega_j$ and $D^\pm_j$, and hereafter called spectrally flowed representations. More precisely, for $|\omega| > 1$, automorphism \cite{32} does generate new representations; however, the cases $\omega = \pm 1$ are special in the sense that the highest (and lowest) weight representations of the sector $\omega = 0$ coincide with lowest (resp. highest) weight representations of the sector $\omega = -1$ (resp. $\omega = +1$). This results in the identification of the discrete representations

$$D^\pm_{\frac{\omega}{2}-j} \leftrightarrow D^\pm_{\omega=\pm 1} ,$$  \hfill (33)

which will be crucial for the argument herein.
The new Kac-Moody primaries $|j, m, \omega\rangle$, which are annihilated by the positive modes of the new (spectrally flowed) currents, are essential to construct the string spectrum [1]. Algebraically, these states are defined as those that obey

$$J_3^0 |j, m, \omega\rangle = \left( m + \frac{k}{2} \omega \right) |j, m, \omega\rangle,$$

$$\bar{J}_3^0 |j, \bar{m}, \omega\rangle = \left( \bar{m} + \frac{k}{2} \omega \right) |j, \bar{m}, \omega\rangle,$$

(34)

together with

$$J_\pm^\pm |j, m, \omega\rangle = 0,$$

$$\bar{J}_\pm^\pm |j, \bar{m}, \omega\rangle = 0.$$

(35)

In the case of long strings, corresponding to states of the continuous representations $C_j^{\alpha, \omega}$, the parameter $\omega$ of the spectral flow transformation is interpreted as the winding number of the asymptotic states, associated to the presence of a non-vanishing $B$-field in the background. In the case short strings, those described by states of the discrete representations $D_j^{\pm, \omega}$, the geometrical interpretation of $\omega$ is less clear, but it still contributes to the mass-shell condition in a way that resembles a winding number.

Due to the duality among different representations (33), it will be enough for our purpose to consider the spectral flow sector $\omega = 0$. In terms of the Wakimoto fields, the vertex operators that create the states of this sector take the form

$$\Phi_{j, m, \bar{m}}^{\omega=0}(z) = c_0 \gamma^{j-m}(z) \gamma^{\bar{j}-\bar{m}}(\bar{z}) e^{\sqrt{2} k \phi(z, \bar{z})},$$

(36)

where $c_0$ is a normalization constant that here we will set to 1 for convention. It can be easily checked that operators (36) of the spectral flow sector $\omega = 0$ have the following OPE with the $sl(2)$ Kac-Moody currents

$$J_3(z) \Phi_{j, m, \bar{m}}^0 (w) \simeq \frac{m}{(z-w)} \Phi_{j, m, \bar{m}}^0 (w) + \ldots$$

(37)

$$J_\pm^\pm (z) \Phi_{j, m, \bar{m}}^0 (w) \simeq \left( \frac{\pm j - m}{(z-w)} \right) \Phi_{j, m+1, \bar{m}}^0 (w) + \ldots$$

(38)

which realize (34)-(35) for $\omega = 0$.

Vertex operators $\Phi_{j, m, \bar{m}}^\omega$ are the objects that create the states $|j, m, \omega\rangle \times |j, \bar{m}, \omega\rangle$ out of the $SL(2, \mathbb{R}) \times SL(2, \mathbb{R})$ invariant vacuum $|0\rangle$; namely

$$\lim_{z \to 0} \Phi_{j, m, \bar{m}}^\omega (z, \bar{z}) |0\rangle = |j, m, \omega\rangle \times |j, \bar{m}, \omega\rangle.$$

(39)
The conformal dimension of these states is given by

\[ h_{j,m}^\omega = -\frac{j(j+1)}{k-2} - m\omega - \frac{k}{4}\omega^2, \quad h_{j,m}^{-\omega} = -\frac{j(j+1)}{k-2} - m\omega - \frac{k}{4}\omega^2 \tag{40} \]

Notice that, indeed, the states \(|j, \pm j, 0\rangle\) and \(|-k/2-j, \pm k/2 \pm j, \mp 1\rangle\) have the same quantum numbers, in accordance to (33). That is, they have the same eigenvalue under the conformal weight \(h_{j,m}^\omega\), and the same conformal weight \(h_{j, \pm j}^\omega = h_{-k/2-j, \pm k/2 \pm j}^\omega\). The formula for the conformal weight \(h_{j, \pm j}^\omega\) also remains unchanged under the Weyl reflection \(j \rightarrow -1 - j\). That is, the states \(|j, m, \omega\rangle\) and \(|-1 - j, m, \omega\rangle\) have the same quantum numbers, and in particular \(h_{j,m}^\omega = h_{-1-j, \pm m}^{-\omega}\).

Consider now the maximally winding violating correlation function

\[ X_{n}^{2-n} = \prod_{a=1}^{2} \Phi_{-j, a, m_a, m_a}^0(z_a, \bar{z}_a) \prod_{i=3}^{n} \Phi_{j, i, j_i}^0(z_i, \bar{z}_i) \tag{41} \]

which involves \(n-2\) highest-weight states of the spectral flow sector \(\omega = 1\) (the argument works for \(\omega = -1\) as well). In virtue of (33) we can equal this correlator to the following one

\[ X_{n}^{2-n} = c^{2-n} \prod_{a=1}^{2} \Phi_{-j, a, m_a, m_a}^0(z_a, \bar{z}_a) \prod_{i=3}^{n} \Phi_{-\frac{1}{2}j, \frac{1}{2}j+i, \frac{1}{2}j+i}^0(z_i, \bar{z}_i) \tag{42} \]

which only involves vertices \(\frac{1}{2}\), of the sector \(\omega = 0\). This is different to the computation done above, where the presence of vertices with \(\omega \neq 0\) demands the inclusion of extra fields.

The factor \(c^{2-n}\) in (42) stands for the relative normalization between the operators \(\Phi_{j, \pm j, \pm j}^0\) and \(\Phi_{-\frac{1}{2}j, \frac{1}{2}j+i, \frac{1}{2}j+i}^0\), which remains unspecified [11].

Involving only operators of the unflowed sector, correlator (42) admits to be computed by using the Wakimoto representation [36], straightforwardly applying the techniques described in reference [22], with no need of auxiliary fields cf. [15] [16]. This results in

\[ X_{n}^{2-n} = c^{2-n} \prod_{a=1}^{2} \Gamma(-j_a - m_a) \prod_{i=1}^{n} |z_i - z_j|^{-\frac{1}{2}(j_i+j_j)} \prod_{r=1}^{s} d^2 w_r \prod_{r=1}^{s} \prod_{i=1}^{n} |z_i - w_r|^{-\frac{1}{2}(j_i+j_r)} \prod_{r<t}^{s} |w_t - w_r|^{-\frac{1}{2}}, \tag{43} \]

where

\[ s = -1 - \sum_{i=1}^{n} j_i - k(2-n) \tag{44} \]

\[ f = -1 - \sum_{i=1}^{n} j_i - k(2-n) \]
and $b_{ij} = 0$ for $i, j > 3, 4, \ldots n; b_{ai} = j_a$ for $a = 1, 2$ and $i > 2; b_{ab} = j_a + j_b - 2b^2$ for $a, b = 1, 2$.

The integrand in (43) follows from the operator product expansions

$$\gamma(z_a)^{j_a-m_a} \bar{\gamma}(\bar{z}_a)^{j_a-m_a} \prod_{r=1}^{s} \beta(w_r) \bar{\beta}(\bar{w}_r) \simeq \frac{\Gamma^2(1 + j_a + m_a + s)}{\Gamma^2(1 + j_a + m_a)} \prod_{r=1}^{s} |z_a - w_r|^2 + \ldots$$

and

$$e^{-\sqrt{\frac{4}{\pi}} \phi(w, \bar{w})} \prod_{r=1}^{s} e^{-\sqrt{\frac{4}{\pi}} \phi(w_r, \bar{w}_r)} \simeq \prod_{r=1}^{s} |z_a - w_r|^{-\frac{4}{\pi} (j_a+1)} + \ldots,$$

where the ellipses stand for subleading contributions with less Wick contractions. Recall that the $\beta$-dependent operators

$$\int d^2 w \ \beta(w) \bar{\beta}(\bar{w}) e^{-\sqrt{\frac{4}{\pi}} \phi(w, \bar{w})}$$

(45)
come from the interaction term of the $SL(2, \mathbb{R})$ WZW action when written in the Wakimoto representation [22] and, in the Coulomb gas approach, they act as certain amount $(s)$ of screening operators needed to compensate the dilatonic background charge.

The integral on the right hand side of (43) can also be identified as a correlation function in Liouville field theory. More precisely, the $n$-point function of exponential primary operators in Liouville theory takes the form [25]

$$\left< \prod_{i=1}^{n} V_{\alpha_i}(z_i, \bar{z}_i) \right>_{L} = \Gamma(-s) \prod_{i<j}^{n} |z_i - z_j|^{-4\alpha_i \alpha_j} \int \prod_{r=1}^{s} d^2 w_r \prod_{i=1}^{n} \prod_{i<j}^{n} |z_i - w_r|^{-4\alpha_i} \prod_{r<t}^{s} |w_t - w_r|^{-4b^2}$$

(46)

with

$$bs + \sum_{i=1}^{n} \alpha_i = Q, \quad Q = b + \frac{1}{b}.$$  (47)

In these variables, the Liouville central charge reads $c = 1 + 6Q^2$. Then, the dictionary between (43) and (46) is simple and is the one of [11]; namely

$$\alpha_i = b \left( j_i + \frac{b^2}{2} + 1 \right), \quad b^2 = \frac{1}{k - 2}.$$  (48)

In conclusion, we arrive to the formula

$$X_{n}^{2-n} = e^{2-n} \prod_{i=1}^{2} \frac{\Gamma(\alpha_i - m_i)}{\Gamma(1 + j_i + m_i)} \prod_{i<j}^{n} |z_i - z_j|^{2b_{ij}} \left< \prod_{i=1}^{n} V_{\alpha_i}(z_i, \bar{z}_i) \right>_{L}. \quad (49)$$
which is analogous to the one conjectured in [11] and what we actually wanted to prove.

In conclusion: We have derived formula (49), which expresses the $n$-point function of maximally winding violating processes in $\text{AdS}_3$ in terms of $n$-point correlation functions of Liouville field theory. This is analogous to the expressions proposed in [11], here obtained in a remarkably succinct way without resorting to nothing but well-known dualities among spectrally flowed representations and to the standard Wakimoto fields, with no need of auxiliary fields cf. [15] [16].

Despite its simplicity, the derivation presented here has to be regarded as complementary to that presented in the previous sections, and by no means as its generalization. This is because the one here has its limitations as well: it only involves states with winding numbers $\omega = 0, \pm 1$ and deals with the cases in which the $n - 2$ states with $\omega \neq 0$ belong to the highest or lowest weight representations. Still, this is the simplest derivation of winding violating processes in $\text{AdS}_3$ and the simplest example of WZW-Liouville correspondence given so far.
