The Determinants of Profitability in Listed Enterprises: A Study from Vietnamese Stock Exchange

Thi Ngoc Lan NGUYEN¹, Van Cong NGUYEN²

Received: September 10, 2019 Revised: November 01, 2019 Accepted: November 15, 2019

Abstract

The research aims to investigate the determinants of the financial performance of 1343 Vietnamese companies categorized into six different industries listed on the Vietnamese Stock Exchange over a four-year period from 2014 to 2017 using STATA software. Those determinants include firm size, liquidity, solvency, financial leverage, and financial adequacy while the financial performance is evaluated by three different ratios: return on assets (ROA), return on equity (ROE), and return on sales (ROS). The research results from these companies during the given period indicate that: (1) Firm size has a positive impact on both ROA and ROS, especially ROA but it has the opposite effect on ROE, (2) Adequacy ratio impacts positively on ROA and ROS but negatively on ROE, (3) Financial leverage considerably negative influences on ROE and ROS but positively impacts on ROA, (4) Liquidity has a positive effect on both ROA and ROE but a negative one on ROS and (5) Solvency has a positive impact on ROA and ROS but the negative impact on ROE. Furthermore, agriculture accounted for the highest percentage of profitability at the beginning, which was replaced by service for ROA from 2016 to 2017 as opposed to the least in transportation.

Keywords: Profitability Determinants, Vietnamese Listed Enterprises, Vietnam Stock Exchange

JEL Classification Code: G31, G32, L25

1. Introduction

Profitability is one of the vital elements for performance evaluation, showing the proportion of profit in comparison with asset investment, equity, or sales. Improving profitability is one of the key tasks for enterprises, especially in the context of international economic integration today in Vietnam. Because only a stable economy with high profitability can provide enough financial resources for sustainable development, therefore, can attract attention and investment from internal and international investors. Not only being a reliable basis for evaluating business performance, profitability also is a useful tool for forecasting the performance of businesses in the future. Profitability reflects shareholders’ wealth, and accordingly, appeals to investors. This is the reason why identifying different factors affecting directly or indirectly to profitability is an essential research theme in economics, strategic management, accounting and finance.

Over time, many researchers have paid attention to an optimal capital structure that progresses the enterprises’ profitability (Bradley, Jarrell, & Kim, 1984; DeAngelo & Masulis, 1980; Miao, 2005). Besides, it is also necessary to classify other factors influencing directly to profitability such as financial leverage, solvency, liquidity, and financial adequacy. Many authors indicated eight different factors affecting the profitability in the enterprises, which are FIRM SIZE, capital structure, liquidity, solvency, sensitivity, the overhead cost to revenue ratio, and economic growth (Grau, & Reig, 2018; Blažková, 2018; Fareed, Ali, Shahzad, Nazir, & Ullah, 2016; Szymańska, 2017; Jumono, Sugiyanto, & Mala, 2019; Mohanty & Krishnankutty, 2018; Pattitoni, Petracci, & Spisni, 2014; Yüksel, Mukhtarov, Mammadov,
However, these findings are mostly established in developed countries with a significant economics gap comparing to Vietnam, leading to misappropriation in applying concepts. Additionally, these researchers mainly narrow their focus on a specific area of only one industry instead of tackling a vast array of fields. Therefore, the aim of this study is to carry out a broader empirical test, using both quantitative and qualitative methodology, to compare profitability in different industries, and to determine firm-specific determinants.

In order to overcome some of the above problems, this article will solve these problems by examining five internal factors include size, liquidity, solvency, financial leverage, and capital adequacy, which affect the profitability of the listed companies in Vietnamese stock exchange. Although other macro factors, which are economic growth, employment, innovation, and technological change, can explain the variation in profitability of a firm, these factors are assumed remaining stable in the given period, and therefore, can be ignored in this case.

Research data was collected from financial statements of 1343 companies listed on the Vietnamese stock exchange provided by the State Securities Commission of Vietnam. These companies were selected based on the availability of their annual reports between 2014 and 2017. To ensure the representativeness, completeness, and reliability of the collected samples, data was collected based on the following criteria:

**Time period:** The study period is between 2014 and 2017, when the Vietnam stock market witnessed positive changes in comparison with a downward trend in VN-index between 2008 and 2012. This is because 2017 marked the beginning of unexpected success of Vietnam's economy when GDP accounted for 6.8%, showing approximately 1% higher than the figure for the period of 2011-2016 with 5.96% on average. Moreover, despite significant GDP growth, inflation is under control as a result of the Vietnamese Government's policy on prioritizing inflation management. The average CPI in 2017 increased only by 3.53% compared to 2016. This is a tremendous improvement in comparison with the crisis in 2008, when GDP increased to 8.48% and CPI rose to 8.3%, leading to the transformation in listed companies in Vietnam.

**The industries:** Observations are based on the financial statements collected from 1343 listed companies in Vietnam stock exchange, categorized into six different industries: Wholesale and retail, manufacture, mining, agriculture, transportation, and service. The classification is based on the documents that Ho Chi Minh Stock Exchange announced.

**The sources:** Research data is collected from secondary data published publicly by the State Securities Commission and securities companies. Therefore, this data ensures the reliability, transparency and accuracy (Cafef, 2018; Cophieu68.vn, 2018; Hanoi Stock Exchange, 2018; Ho Chi Minh Stock Exchange, 2018; VietstockFinance, 2018).

**The number of observations:** With 1343 surveys (accounting for 100% of the sample size), 5372 observations are conducted to get the best estimate. On that basis, a regression model is established for analysis and verification with the help of specialized software STATA version 2015.

  - Cyclical output
2. Literature Review

Many studies examining the determinants of profitability have been done in listed enterprises, especially in a particular industry such as banking, insurance, manufacture, or real estate. The findings indicate that there are three different categories that those determinants can be classified into: Intentional firm variables, industry variables, and economics environment variables in accordance with several theoretical perspectives. The most famous five theories which can be applied for finding the factors affecting the profitability as well as business performance are: Market-based view (MBV), the resource-based view (RBV), the structure-conduct-performance (SCP) and the organization environment structure performance (OESP).

In MBV, many authors believe that the competitive advantages of a firm are generated mostly by the industrial organization economics, taking benefits from external market to achieve higher returns which are measured by the profitability and the firm values (Chamberlain, 1962; Gilbert, 1989; Molloy & Barney, 2015; Zheng, Liu, & Huang, 2019). In contrast - in RBV - it can be said that the profitability is provided as a result of the distinct of different resources such as human resources, machines, and technology, leading to a significant difference in the research results (Bromiley & Rau, 2016; Grant, 1991; Hitt, Xu, & Carnes, 2015; Peteraf, 1993; Wernerfelt, 1984). Researchers with SSP view, think that a firm’s strategy, created in consideration of external environmental factors, drives the development of organizational structure and processes, then helps the firm with better performance than competitors who lack the same degree of strategic fit (Defee & Stank, 2005; Galbraith & Nathanson, 1978; Galunic & Eisenhardt, 2000; Miles, Snow, Meyer, & Coleman, Jr., 1978). The research results of the SSP theory illustrate that the market environment can influence directly and considerably on the market structure, resulting in the significant impact on the firm’s value (Chamberlain, 1962; Edward, 1933; Kuenne, 1967; Robinson, 1933). Furthermore, many external factors including legal political interventions affect the market framework and, by extensionally, the structure, conduct and performance of the market.

Finally, developed Child (1972) OESP states that for all businesses, the super-ordinated goals which are evaluated by shared values mainly rely on six different organizational environmental factors (6S): Strategy, structure, systems, staff, style, and skills. Similarly, Cosh, Fu, and Hughes (2012), Lenz (1980) indicated that performance of enterprises is varied in accordance with a combination of environment, strategy, and organization structure; and the reason why some organizations achieved higher performance than the others is due to the differences in these four factors. They ensured that such combinations differ, the achieved performances of different enterprises are varied. Additionally, they found many statistic evidence to ensure that those four factors are “norms held by managers of competing institutions and are the nature of the relationship between organizations and populations served to influence the vigour and form of interfirm and, in turn, organization performance” (Lenz, 1980).

Empirical studies also classified the different factors responsible for the profitability into two major groups. The first group contains internal factors such as financial leverage, financial solvency, financial adequacy, financial independence, liquidity, firm size, growth, capital structure, firm ages, and other management decisions (Anbar & Alper, 2011; Aburime, 2009; Blažková, 2018; Capon, Farley, & Hoenig, 1990; Grau & Reig, 2018; Huang & Song, 2006). The second group takes concentration on the external factors classified into two different indicators: industrial-level indicators and macro-level indicators. While industrial-level indicators include market concentration, sector growth rate, and growth rate of imports, macro-level indicators contain the growth rate of Gross Domestic Product, inflation, interest rate, financial market returns (Grau & Reig, 2018; Pattitoni, Petracci, & Spisni, 2014).

According to Szymańska (2017), the ROE of pork manufacturing companies is determined by the high fragmentation of the industry, limited specialization, and customer confidence. Particularly, the author used the detailed annual financial statements of 86 meat companies in Poland from 2008 to 2012, then calculated the profitability through five different ratios, which are the ROA, ROE, ROS, assets turnover ratio, and equity multiplier before making a comparison among the given enterprises. She concluded that the most important internal factors affecting the profitability of these companies are the company’s assets value and structure, liquidity, sale development, capital structure, working capital management efficiency, production process organization, and employee quality. Nevertheless, the external factors shaping the profitability of meat enterprises are climate, policy, legal systems, business cycle, interest rate, and inflation rate. Likewise, Sivathaasan, Tharanika, Sinthuja and Hanitha (2013) study the factors affecting the profitability of all manufacturing companies listed on the Colombian and Sri Lankan stock exchanges from 2008 to 2012. The independent variables (influencing factors) used for the research are capital structure, asset structure, company size, and growth rate, while dependent variables representing the profitability are ROA and ROE. In which, only capital structure has a positive impact on the profitability of companies, while the structure of assets, company size and growth rate have no effect on ROA and ROE.

Lazaridis and Tryfonidis (2006) collected data from 131 companies listed on the Athens Stock Exchange in the period 2001 - 2004 to find out the relationship between capital structure and profitability. The research results show that the cash conversion cycle and debt ratio have the opposite effect on the profitability of the business, as opposed to the positive impact of firm size and the ratio of fixed assets to total assets. Alshatti (2015) conducted research on 13 commercial banks in Jordanian in the eight-
year period from 2005 to 2012 in order to evaluate the relationship between solvency and profitability. Findings show that the quick solvency ratio and investment ratio have a positive impact on the profitability of banks, while the equity ratio and instant solvency ratio are, on the other hand, negative factors. Evaluating the relationship between working capital management and profitability, Gill, Biger, and Mathur (2010) studied 88 companies listed on the New York Stock Exchange between 2005 and 2007. The results show that the average collection period, debt ratio, and fixed assets ratio negatively affect the profitability of the business whereas the revenue growth is on the reverse pattern.

In Vietnam, the number of researches investigating the determinants of profitability is very small. Research by Dong and Su (2010) focused on the influence of fixed asset ratio, cash conversion cycle, average collection period and inventory turnover on the profitability of listed companies in Vietnam's stock exchanges in the period from 2006 to 2008. They concluded that the cash transfer cycle has a negative impact on the profitability of enterprises in comparison with positive impact generated from fixed asset ratio, and average collection period. Tu and Nguyen (2014) used regression analysis of panel data collected from 208 listed companies on both Ho Chi Minh City Stock Exchanges and Hanoi Stock Exchanges to examine the relationship between working capital and profit management in the period from 2006 to 2012. Research results found that the cash conversion cycle plays a significant role in influencing the profitability of businesses.

In summary, the results of the literature review above have shown that most studies took concentration dominantly on a specific industry and on some specific factors affecting profitability. However, profitability is subjected to simultaneous effects of many factors and profitability is varied across sectors. This has led to a lack of extensive and comprehensive research on the economy as a whole and a specific comparison among different industries' profitability. In fact, both practical and theoretical researches conducted in developed countries indicate that the relationship between the internal factors and profitability has existed, but the researching methods and conclusions of different researches are still conflicted. Furthermore, since Vietnamese listed companies represent distinct characteristics with noticeable differences in comparison with international markets, it is necessary to have a new theoretical and practical concept for determining the profitability determinants. Therefore, this research will solve the contraries in previous researches and create a new model focusing on the impact of internal factors on profitability in different industries. These factors are size, liquidity, solvency, financial leverage, and capital adequacy collected based on financial statements published in Vietnam stock exchanges. We pay special attention to make a comparison among different Vietnamese industries' profitability through ROA, ROE, and ROS ratio.

3. Hypothesis, Empirical Model and Research Methods

3.1. Hypothesis

H1: Firm size is positively correlated with profitability.

In their research, Nanda and Panda (2018) have focused on finding the firm-specific and macroeconomic determinants of profitability in manufacturing companies by gathering the information collected on the Indian stock market between 2000 and 2015. The empirical models showed that: The firm size enhances the financial performance according to the significant increase in ROA as well as net profit margin. Similarly, Babalola (2013), Baumol (1985), Blundell, Griffith, and Reenen (1999), Doğan (2013) agree with this hypothesis since they believe that an increase and upgrade in the financial capital can help the enterprise with capacity improvement, then market share extension before taking the competitive advantages to achieve higher profitability. Furthermore, it can be clearly seen that a larger firm always has more resources than a smaller firm, leading to a higher production scale, therefore, the larger firm can expect a higher return rate.

H2: Capital adequacy has a positive impact on profitability.

According to Ebenezer, Oma, and Kamil (2017), the capital adequacy is positively correlated with the profitability in sixteen commercial banks selected in Nigeria between 2010 and 2015. Similarly, Sufian and Habibullah (2009) examined the impact of capital adequacy on the profitability in banking sectors with 220 observations during the period of 5 years from 2000 to 2005, then they found out that a positive correlation between the capital adequacy and the profitability has existed. Having the same idea with previous researchers, Athanasogloua, Brissimisa, and Delis (2008) used SCP hypothesis with the support of GMM technique in order to illustrate that the capital adequacy positively significant influences ROA in Chinese commercial banks. This is because a bank with a sound capital position is able to pursue business opportunities more effectively and it has more time as well as the flexibility to deal with problems arising from unexpected losses, and therefore it is enabled to achieve higher profitability.

H3: Liquidity is positively correlated with profitability.

The studies of Deloof (2003), Nickell and Nicolitisas (1999), Pattitoni, Petracci, and Spisni (2014), Serrasqueiro and Nunes (2008) all have the same idea of the positive correlation between the liquidity and the profitability of enterprises. Particularly, Pattitoni, Petracci, and Spisni (2014) based on the research results of Goddard, Tavakoli, and Willson (2006) to develop four models with data collected from multi-industries and multi-countries and found that all
four models illustrate a strong positive relationship between the independent variables measured by the liquidity ratio and the dependent variable measured by the ROE. This is because the “high level of liquidity can reduce the effects of adverse changes in the economic environment, the risk of being unable to repay short-term debts and the risk of losing profitable investment opportunities due to financial constraints” (Nickell & Nicolitsas, 1999).

H4: Financial leverage has a negative impact on profitability.

According to Pattitoni, Petracci, and Spisni (2014), the more debt used, the fewer returns on equity are achieved. In fact, if the companies acquire more debt, they have to pay out more interest expense, leading to cash constraints due to periodic debt payments, then faced with financial difficulties before witnessing a decline in operating performance. Likewise, Ahmad, Salman, and Shamsi (2015) indicated that financial leverage has a statistically significant inverse impact on profitability at 99% confidence interval. This is due to the fact that the more debts companies acquired to finance assets, the more financial expenses they have to pay for interest, leading to remaining profit reduction, thereby reducing profitability. This hypothesis is conducted as a result of many previous studies (Benito & Gertjan, 2000; Singapurwoko & El-Wahid, 2011; Vintilă & Duca, 2012).

H5: Solvency has a positive impact on profitability.

Based on the research findings of Alshatti (2015), it can be said that the solvency ratio positively affects profitability. This is because the higher the solvency would be, the greater the level of financial stability that enterprises could achieve, helping the enterprises with financial independence and financial security improvement. Thus, the enterprise would be able to progress productivity and efficiency, thereby achieving the goal of profitability enhancement.

3.2. Empirical Model

In this research, the authors will follow the method of quantitative research into regression models: firm size, capital adequacy, liquidity, financial leverage, and solvency are the independent variable, whereas three profitability ratios (ROA, ROE, and ROS) are dependent variables, with the assistance of STATA version 2015. After going through the literature reviews, the financial performance of the firm’s indicators has been identified, which are ROA, ROE, and ROS. This research use panel data to evaluate the impact of five different factors including firm size, adequacy ratio, liquidity ratio, financial leverage, and solvency ratio on the profitability, which is measured by the ROA, ROE, and ROS of six different industries in Vietnam between 2014 and 2017.

Model 1: \[ \text{ROA}_{i,t} = \alpha_0 + \alpha_1 \times \text{SIZ}_{i,t} + \alpha_2 \times \text{ADE}_{i,t} + \alpha_3 \times \text{LIQ}_{i,t} + \alpha_4 \times \text{LEV}_{i,t} + \alpha_5 \times \text{SOL}_{i,t} + \epsilon_{i,t}. \]

Model 2: \[ \text{ROE}_{i,t} = \alpha_0 + \alpha_1 \times \text{SIZ}_{i,t} + \alpha_2 \times \text{ADE}_{i,t} + \alpha_3 \times \text{LIQ}_{i,t} + \alpha_4 \times \text{LEV}_{i,t} + \alpha_5 \times \text{SOL}_{i,t} + \epsilon_{i,t}. \]

Model 3: \[ \text{ROS}_{i,t} = \alpha_0 + \alpha_1 \times \text{SIZ}_{i,t} + \alpha_2 \times \text{ADE}_{i,t} + \alpha_3 \times \text{LIQ}_{i,t} + \alpha_4 \times \text{LEV}_{i,t} + \alpha_5 \times \text{SOL}_{i,t} + \epsilon_{i,t}. \]

Where: \( \alpha_0, \alpha_1, \alpha_2, \alpha_3, \) and \( \alpha_4,\alpha_5 \) are correlation coefficients. \( \epsilon_{i,t} \) is error of company \( i \) in year \( t \).

ROA: is a dependent variable, reflecting the profitability of assets and is calculated by Profit after tax/Total assets.

ROE: is the dependent variable, reflecting the profitability of equity and is calculated by Profit after tax/Equity.

ROS: is the dependent variable, reflecting the profitability of sales and is calculated by Profit after tax/Sales.

SIZ (Firm size): is the independent variable, reflecting the firm’s size and is calculated by Log (Total asset).

ADE (Capital adequacy): is the independent variable, reflecting the equity ratio and is calculated by Equity/Total asset.

LIQ (Liquidity): is the independent variable, reflecting the liquidity and is calculated by Short-term assets/Short-term liability.

LEV (Financial leverage): is the independent variable, reflecting the financial leverage and is calculated by Total liabilities/Equity.

SOL (Solvency ratio): is the independent variable, reflecting the financial leverage and is calculated by (Equity + Total liabilities)/Total liabilities.

3.3. Research Method

Sample collection and processing process:

Step 1: Search the list of listed companies.

Get a full list of Vietnamese companies listed on HOSE and HNX until 31/12/2017. A total of 1343 companies listed with full names, stock codes and securities transactions. Classify all companies into six different industries according to HOSE’s criteria: (1) 204 wholesale and retail companies, (2) 433 service companies, (3) 91 agriculture companies, (4) 452 manufacture companies, (5) 85 transportation companies, and (6) 78 mining companies.

Step 2: Collect financial statements.

Search for audited annual financial statements and annual reports of all 1343 companies in the four years from 2014 to 2017. The total number of reports obtained by all 1343 companies is 5372 (total observation is 1343*4=5372 units).

Step 3: Calculate the value of the index and clean the data.

Calculate the profitability ratio (ROA, ROE, ROS) as dependent variables together with internal financial ratio such as firm size, liquidity, solvency, leverage, and financial adequate. This is followed by a checking step to remove specific data samples if ROA is greater than ROE or ROA cannot be calculated.

After this step, remaining observations for each industry are presented as Table 1.
4. Results

4.1. Descriptive Analysis

In order to make a comparison of performance among six different Vietnamese industries between 2014 and 2017, it is necessary to evaluate their sales, profit, and profitability during the given period. Overall, the amount of money collected from revenue in the wholesale and retail industry accounted for the highest number as opposed to the least recorded in agriculture during four given years. Furthermore, a significant increase was seen in the number of sales in mining, transportation, and service companies while a noticeable decline was witnessed in the other companies from 2014 to 2017. Specifically, started at the highest point at approximately 4,000,000 million Vietnam Dong in 2014, the number of sales in wholesale and retail declined remarkably by 1,000,000 million VND in 2015 before going to a low of 2,700,000 million VND in 2016. By contrast, a slight fluctuation in an upward trend was seen in the service and wholesale and retail respectively. By contrast, starting at the second-highest point of approximately 130,000 million VND in 2014, the agriculture’s profit suddenly declined twice to 60,000 million VND in 2015 before reaching a low of 761 million VND in 2016. For ROA of six industries (wholesale and retail, service, agriculture, manufacture, mining, and transportation) from 2014 to 2017, in general, significantly decreased in the range from 1.09% to 9.97%. Starting at the highest point of 6.8% in 2014, the ROA of agriculture reduced slightly by 0.3% in 2015, after which the figure witnessed a considerable decline of approximately 4.5% in the final year. While the figure for manufacture and transportation saw a strong fluctuation of from 5.64% to -4.33% and 3.49% to -1.11% respectively, the figures for the other enterprises remained stable with a minimal decline of approximately 1% during the given period.

Figure 2 shows the changes in ROE ratios in six different Vietnamese industries from 2014 to 2017. Units are measured in percent. What stands out from the chart is that stability was seen in ROE of all industries except for transportation which witnessed a strong fluctuation of approximately 60% during the given period. Moreover, manufacturing companies always made up the highest proportion of ROE with approximately 15% in 2017, showing twice higher than the figure for wholesale and retail enterprises. ROE of mining and service industries declined by 5% and 10% respectively in 2017 from the same proportion of 8% in 2014. The difference between ROA of transportation and agriculture was tremendous with 55% more ROE earned by agriculture.
Also during 2014-2017, ROS increased significantly in the number of wholesale and retail, and transportation industries as opposed to an enormous decline recorded in other industries. At the beginning, agriculture’s ROS made up the highest percentage of 12%, mining and transportation enterprises’ numbers accounted for the lowest at -11% and -6% respectively. 2015 witnessed a tremendous decrease in ROE for all enterprises in Vietnam except for manufacturing with an increase of 6% while 2016 marked a reverse pattern. In 2017, ROS in manufacture and service went down by 30% and 5% in comparison with 2% and 40% growth in the figure for wholesale and retail and mining respectively.

Due to the sample collection limitation and the profitability changes in six different industries in Vietnam between 2014 and 2017, this study takes concentration on evaluating and examining the profitability in two industries only: service (1516 observations with over 90% of representative), and manufacture (1236 samples with approximately 70% of representative).

4.2. Correlation Analysis

Table 2 illustrates the number of observations, median, standard deviation, min, and a max of three different independent variables (ROA, ROE, and ROS) as well as five different dependent variables (SIZ, ADE, LIQ, LEV, and SOV) in 1343 companies in Vietnam between 2014 and 2017. In general, while the mean of ROA is 0.01954, that of ROE and ROS are 0.05577 and -0.0711 respectively. Additionally, the profitability in these enterprises is tremendously different with the largest amount off standard deviation recorded in the figure for ROE.

Table 3 shows the correlation among variables in 1343 companies in Vietnam in the period from 2014 to 2017. What stands out from the table is that all independent variables have a low level of correlation with each other except for ADE and LEV with -0.6882. This would mean that it would hopefully no autocorrelation phenomenon among six different independent variables. Additionally, while SIZ, ADE, and LIQ have a positive correlation with all three profitability ratios, LEV impacts negatively on ROA, ROE, and ROS.

Table 2: Variable Summary

| Variable | Obs. | Mean  | Sd.   | Min    | Max     |
|----------|------|-------|-------|--------|---------|
| ROA      | 4330 | 0.01954 | 0.93957 | -55.316 | 1.3606  |
| ROE      | 4328 | 0.05577 | 1.50629 | -51.111 | 13.2099 |
| ROS      | 4315 | -0.0711 | 2.7938  | -126.96 | 18.6616 |
| SIZ      | 4354 | 5.55703 | 0.68446 | 2.70501 | 8.12699 |
| ADE      | 4350 | 0.4677  | 0.66247 | -18.521 | 1.25557 |
| LIQ      | 4349 | 4.8345  | 102.039 | 0.00016 | 6232.18 |
| LEV      | 4349 | 1.92659 | 12.6102 | -0.6882 | 667.969 |
| SOL      | 4349 | 6.54463 | 182.445 | -831.27 | 10653.6 |

Table 3: Variable Correlation

|          | ROA  | ROE  | ROS  | SIZ  | ADE  | LIQ  | LEV  | SOL  |
|----------|------|------|------|------|------|------|------|------|
| ROA      | 1    | 0.0033 | 0.1363 | 0.0811 | 0.4762 | 0.0129 | -0.2129 | -0.0022 |
| ROE      |      | 1    | 0.0144 | 0.0171 | 0.0079 | 0.0065 | -0.006 | 0.151 |
| ROS      |      |      | 1    | 0.0123 | 0.108  | -0.0209 | 0.0004 | 0.001 |
| SIZ      |      |      |      | 1    | -0.0209 | 0.0004 | -0.0404 | -0.018 |
| ADE      |      |      |      |      | -0.6882 | -0.0404 | 0.0703  | 0.0101 |
| LIQ      |      |      |      |      |      | 0.0703  | 1    | 0.009  |
| LEV      |      |      |      |      |      |      | 0.0177 | 1    |
| SOL      |      |      |      |      |      |      |      | 1    |

4.3. Regression Models

4.3.1. ROA Model
Table 4 shows the regression results for the ROA model in terms of Fixed Effects, Random Effects, and Generalize Method. In order to determine and evaluate the reliability and rationality of this model, it is necessary to use the following tests:

Hausman Test to choose between FEM or REM model
Because the $P_{value}$ (Hausman Test) = 0 < 0.05 $\Rightarrow$ $H_0$ is rejected $\Rightarrow$ REM model is not suitable
In conclusion, the FEM model is suitable for Model 1.
Test of changes in error variances
Because $P_{value}$ = 0 < 0.05 $\Rightarrow$ Model 1 has changes in error variances.
Test of autocorrelation
Because $P_{value}$ = 0.0047 < 0.05 $\Rightarrow$ Model 1 has autocorrelation.
Therefore, GMM is applied for Model 1.

Sargan test of overid. Restrictions
Because $P_{value}$ = 0.143 > 0.05 $\Rightarrow$ GMM model is suitable for Model 1.

Model 1: $ROA_{it} = 3.105 + 0.452 \times SIZ_{it} + 0.154 \times ADE_{it} + 0.00638 \times LIQ_{it} + 0.00323 \times LEV_{it} + 0.00185 \times SOL_{it} + 0.00325 \times LEV_{it} + 0.00116 \times ADE_{it}$

Table 4: ROA Model

| VARIABLES | (1) | (2) | (3) |
|-----------|-----|-----|-----|
| SIZ       | 0.118*** | 0.118*** | 0.452** |
| ADE       | 0.985*** | 0.985*** | 0.154*** |
| LIQ       | -0.000132 | -0.000132 | 0.00638 |
| LEV       | 0.0245*** | 0.0245*** | 0.00323 |
| SOL       | 4.65e-05 | 4.65e-05 | 0.00185 |
| L.SIZ     | 6.93e-05 | 6.93e-05 | 0.00146 |
| Constant  | -1.141*** | -1.141*** | -1.173 |
| R-squared | 0.135 | 0.135 |

4.3.2. ROE Model
Table 5 shows the regression results for the ROE model in terms of Fixed Effects, Random Effects, and the Adjusted Fixed Effect. In order to determine and evaluate the reliability and rationality of this model, it is necessary to use the following tests:

Hausman Test to choose between FEM or REM model
Because the $P_{value}$ (Hausman Test) = 0 < 0.05 $\Rightarrow$ $H_0$ is rejected $\Rightarrow$ REM model is not suitable
In conclusion, the FEM model is suitable for Model 2.

Test of changes in error variances
Because $P_{value}$ = 0 < 0.05 $\Rightarrow$ Model 2 has changes in error variances.
Test of autocorrelation
Because $P_{value}$ = 0.3030 > 0.05 $\Rightarrow$ Model 2 has no autocorrelation.

In order to fix the error variances problem in Model 2, it is necessary to apply for this model an adjusted REM as FEM* in Table 6.

Model 2: $ROE_{it} = 1.027 - 0.153 \times SIZ_{it} - 0.204 \times ADE_{it} + 0.00638 \times LIQ_{it} - 0.00640 \times LEV_{it} - 0.00122 \times SOL_{it} + 0.00122 \times LEV_{it}$

Table 5: ROE Model

| VARIABLES | (1) | (2) | (3) |
|-----------|-----|-----|-----|
| SIZ       | -0.153 | 0.0213 | -0.153 |
| ADE       | -0.204** | -0.0351 | -0.204** |
| LIQ       | 0.005059 | 0.000224 | 0.0161-05 |
| LEV       | -0.00640** | -0.00640** | 0.0332 |
| SOL       | -0.00122*** | -0.00122*** | -0.00215 |
| Constant  | -1.027 | -0.0514 | 1.027* |
| R-squared | 0.135 | 0.135 |

4.3.3. ROS Model
Table 6 shows the regression results for the ROS model in terms of Fixed Effects, Random Effects, and the Adjusted Fixed Effect. In order to determine and evaluate the reliability and rationality of this model, it is necessary to use the following tests:

Hausman Test to choose between FEM or REM model
Because the $P_{value}$ (Hausman Test) = 0.0732 > 0.05 $\Rightarrow$ $H_1$ is rejected $\Rightarrow$ FEM model is not suitable
In conclusion, the REM model is suitable for Model 3.

Test of autocorrelation
Because $P_{value}$ = 0.0047 < 0.05 $\Rightarrow$ Model 3 has autocorrelation.
In order to fix the autocorrelation problem in Model 3, it is necessary to apply for this model an adjusted REM as REM* in Table 7.

Model 3: $ROS_{it} = -0.949 + 0.117 \times SIZ_{it} + 0.154 \times ADE_{it} - 0.000899 \times LIQ_{it} - 0.00313 \times LEV_{it} + 5.14 \times 10^{-5} \times SOL_{it} + 0.00215 \times SOL_{it}$

In conclusion, the FEM model is suitable for Model 2.
Test of changes in error variances
Because $P_{value}$ = 0 < 0.05 $\Rightarrow$ Model 2 has changes in error variances.
Test of autocorrelation
Because $P_{value}$ = 0.3030 > 0.05 $\Rightarrow$ Model 2 has no autocorrelation.

In order to fix the error variances problem in Model 2, it is necessary to apply for this model an adjusted REM as FEM* in Table 6.
which is quite short. Moreover, during this time, the crisis of market development in Vietnam, this paper has just studied research result. However, due to the limited time of stock fluctuate greatly in order to produce a highly reliable recovery phase between 2014 and 2017. By contrast, many intended risks, leading to the bias in the research results.

5.1. Conclusion

From the above research results, it can be said that a significant difference can be seen in the impact of five different independent variables on ROA, ROE, and ROS. Specifically, although SIZ has a significant positive impact on ROA but the slight impact on ROS, it has a negative impact on ROE in these enterprises during the given period. Adequacy ratio, on the other hand, impacts positively on ROA and ROS but negatively on ROE. In contrast, liquidity is an indicator with positive effect in both ROA and ROE but a negative effect on the other profitability ratio. Next, financial leverage has a strong positive influence on ROA as opposed to a considerable negative impact on the others. Finally, solvency has a positive impact on ROA and ROS but the negative impact on ROE.

5.2. Limitations

The study is focused on the period of Vietnam’s economy recovery phase between 2014 and 2017. By contrast, many international famous papers require the research time to be relatively long, and during that time the factors should not fluctuate greatly in order to produce a highly reliable research result. However, due to the limited time of stock market development in Vietnam, this paper has just studied and examined the period of four years (from 2014 to 2017) which is quite short. Moreover, during this time, the crisis of global economic finance had a significant impact on the domestic market, resulting in the strong fluctuation in Vietnam economy. This would mean that data collected from Vietnamese enterprises during the given period contains many intended risks, leading to the bias in the research results.

Secondly, empirical data is taken from the financial statements of businesses. The published industry may not yet have absolute accuracy. This may result in the deviations in building and testing regression models that show the impact financial factors on the profitability.

Thirdly, there are very few research topics on the effects of financial factors on the profitability in Vietnamese enterprises. This would result in certain limitations to make verification and comparison between this paper with other empirical studies. Therefore, this research is currently stopping at assessing and explaining the impact of five different indicators on the profitability of 1343 Vietnamese enterprises. Finally, this paper has not taken into account the impact of macro factors such as GDP, inflation, interest rate, and tax rate nor specific industrial factors including competitors, customer preferences, the elasticity of demand by price, and the elasticity of supply by price to the profitability of 1343 companies listed in Vietnam stock market. Therefore, the research results presented have stronger influences on the internal of these enterprises than those of external users.

5.3. Recommendation

5.3.1. For the State

The State plays an important role in ensuring a stable business environment for Vietnamese enterprises, especially for published enterprises to take advantage of opportunities. This would help these enterprises to dominate the market, then promote the development of competitive advantage before improving financial performance. In order to do that, the State needs to promulgate policies with specific guidelines for using loan risks and credit strategy. It is because with high-interest rates, these enterprises will normally face with a high amount of interest expenses, leading to financial difficulties and even bankruptcy risks, especially in medium and small Vietnamese companies. Therefore, the State should implement the following actions to help domestic businesses achieve their goal of improving profitability:

Firstly, the State should regulate the economy and promote the development of Vietnamese enterprises by regulations and law enforcement relating to the use of loans at reasonable interest rates. This would hopefully help these enterprises with danger realization and potential risk prevention if they rely on debt to capital resources. Since these enterprises have not only to pay opportunity costs measured by interest expenses of using capital, but also witness a reduction in financial security because of the significant decline in liquidity and solvency.

Secondly, the State should support Vietnamese enterprises to expand production scale through labour education incentives, production and business premise sustenance, and input guarantee. This would enable Vietnamese businesses to have the ability to approach more customers and expand market shares, then tremendously increase in size before improving profitability.

| Table 6: ROS Model |
|-------------------|
| VARIABLES        | FEM | REM | REM* |
| SIZ              | 0.601*** | 0.148 | 0.117 |
|                  | (0.227) | (0.101) | (0.0914) |
| ADE              | 0.596*** | 0.507*** | 0.484*** |
|                  | (0.136) | (0.110) | (0.108) |
| LIQ              | -0.00130 | -0.00102 | -0.000899 |

|                  | (0.000523) | (0.000293) | (0.000272) |
| Constant         | -3.699*** | -1.139** | -0.949* |
|                  | (1.257) | (0.569) | (0.513) |
| Observations     | 4,304 | 4,304 | 4,304 |
| R-squared        | 0.168 |       |       |
| Number of STT    | 1,224 | 1,224 | 1,224 |
5.3.2. For listed Vietnamese Companies

For listed companies in Vietnam, it is extremely necessary to identify clearly different factors affecting profitability in operating the business since they cannot achieve their goals without profitable influencer recognition. Research results show that increasing the size of enterprises, is the key helping businesses increase profitability. This is because if enterprises expand their firms’ size, they would allow to progress competitive advantages and dominate the market shares.

In addition, Vietnamese businesses should not rely dominantly on debts to maintain their operating capital due to two reasons. The first reason responsible for debt reluctance in enterprises is that an increase in the proportion of debt leads to a rise in financial leverage which has a strong negative impact on both ROE and ROS. Secondly, if an increase in debt is witnessed, both liquidity and solvency of businesses will decrease, affecting directly in the profitability, even leading to financial insecurity and bankruptcy.
