Abstract: In the multidimensional setting, we consider the errors-in-variables model. We aim at estimating the unknown nonparametric multivariate regression function with errors in the covariates. We devise an adaptive estimator based on projection kernels on wavelets and a deconvolution operator. We propose an automatic and fully data driven procedure to select the wavelet level resolution. We obtain an oracle inequality and optimal rates of convergence over anisotropic Hölder classes. Our theoretical results are illustrated by some simulations.

MSC 2010 subject classifications: Primary 62G08.
Keywords and phrases: Adaptive wavelet estimator, anisotropic regression, deconvolution, measurement errors.

Received January 2016.
1. Introduction

We consider the problem of multivariate nonparametric regression with errors in variables. We observe the i.i.d dataset

\[(W_1, Y_1), \ldots, (W_n, Y_n)\]

where

\[Y_i = m(X_i) + \varepsilon_i\]

and

\[W_i = X_i + \delta_i,\]

with \(Y_i \in \mathbb{R}\). The covariates errors \(\delta_i\) are i.i.d unobservable random variables having error density \(g\). We assume that \(g\) is known. The \(\delta_i\)'s are independent of the \(X_i\)'s and \(Y_i\)'s. The \(\varepsilon_i\)'s are i.i.d standard normal random variables, independent of the \(X_i\)'s with variance \(s^2\) which is assumed to be known. We wish to estimate the regression function \(m(x), x \in [0, 1]^d\), but direct observations of the covariates \(X_i\) are not available. Instead due to the measuring mechanism or the nature of the environment, the covariates \(X_i\) are measured with errors. Let us denote \(f_X\) the density of the \(X_i\)'s assumed to be positive and \(f_W\) the density of the \(W_i\)'s.

Use of errors-in-variables models appears in many areas of science such as medicine, econometry or astrostatistics and is appropriate in a lot of practical
experimental problems. For instance, in epidemiologic studies where risk factors are partially observed (see [23], [10]) or in environmental science where air quality is measured with errors ([6]).

In the error-free case, that is $\delta_l = 0$, one retrieves the classical multivariate nonparametric regression problem. Estimating a function in a nonparametric way from data measured with error is not an easy problem. Indeed, constructing a consistent estimator in this context is challenging as we have to face to a deconvolution step in the estimation procedure. Deconvolution problems arise in many fields where data are obtained with measurement errors and has attracted a lot of attention in the statistical literature, see [21] for an excellent source of references. The nonparametric regression with errors-in-variables model has been the object of a lot of attention as well, we may cite the works of [10], [11], [17], [19], [21], [5], [3], [8], [2], [6]. The literature has mainly to do with kernel-based approaches, based on the Fourier transform. All the works cited have tackled the univariate case except for [10] where the authors explored the asymptotic normality for mixing processes. In the one dimensional setting, [3] used Meyer wavelets in order to devise his statistical procedure but his assumptions on the model are strong since the corrupted observations $W_l$ follow a uniform density on $[0,1]$. [5] investigated the mean integrated squared error with a penalized estimator based on projection methods upon Shannon basis. But the authors do not give any clue about how to choose the resolution level of the Shannon basis. Furthermore, the constants in the penalized term are calibrated via intense simulations.

In the present article, our aim is to study the multidimensional setting and the pointwise risk. We would like to take into account the anisotropy for the function to estimate. Our approach relies on the use of projection kernels on wavelets bases combined with a deconvolution operator involving the noise in the covariates. When using wavelets, a crucial point lies in the choice of the resolution level. Actually, the main goal of the paper focuses on how to choose in a calibrated way the multiresolution analysis. It is well-known that theoretical results in adaptive estimation do not provide the way to choose the numerical constants in the resolution level and very often lead to conservative choices. We may cite the work of [12] which attempts to tackle this problem. For the density estimation problem and the sup-norm loss, the authors based their statistical procedure on Haar projection kernels and provide a way to choose locally the resolution level. Nonetheless, in practice, their procedure relies on heavy Monte Carlo simulations to calibrate the constants. In our paper the resolution level of our estimator is optimal, partially data-driven and varies by $x$. It is automatically selected by a method inspired from [14] to tackle anisotropy problems. This method has been used recently in various contexts (see [7], [4] and [1]). Furthermore, we do not resort to thresholding which is very popular when using wavelets and our selection rule is adaptive to the unknown regularity of the regression function. We obtain oracle inequalities and provide optimal rates of convergence for anisotropic Hölder classes. The performances of our adaptive estimator, the negative impact of the errors in the covariates, the effects of the design density are assessed by examples based on simulations.
Adaptive wavelet multivariate regression with errors in variables

The paper is organized as follows. In Section 2, we describe our estimation procedure. In Section 3, we provide an oracle inequality and rates of convergences of our estimator for the pointwise risk. Section 4 gives some numerical illustrations. Proofs of theorems, propositions and technical lemmas are to be found in Section 5.

Notation

Let \( \mathbb{N} = \{0, 1, 2, \ldots\} \) and \( j = (j_1, \ldots, j_d) \in \mathbb{N}^d \), we set \( S_j = \sum_{i=1}^d j_i \) and for any \( y \in \mathbb{R}^d \), we set, with a slight abuse of notation,
\[
2^j y := (2^{j_1} y_1, \ldots, 2^{j_d} y_d)
\]
and for any \( k = (k_1, \ldots, k_d) \in \mathbb{Z}^d \),
\[
h_{j,k}(y) := 2^{S_j} h(2^j y - k) = 2^{S_j} h(2^{j_1} y_1 - k_1, \ldots, 2^{j_d} y_d - k_d),
\]
for any function \( h : \mathbb{R}^d \to \mathbb{R} \). We denote by \( \mathcal{F} \) the Fourier transform of any Lebesgue integrable function \( f \in L_1(\mathbb{R}^d) \) by
\[
\mathcal{F}(f)(t) = \int_{\mathbb{R}^d} e^{-i <t, y>} f(y)dy, \quad t \in \mathbb{R}^d,
\]
where \( <.,.> \) denotes the usual scalar product.

For two integers \( a, b \), we denote \( a \wedge b := \min(a, b) \) and \( a \vee b := \max(a, b) \). And \( \lfloor y \rfloor \) denotes the largest integer smaller than \( y \): \( \lfloor y \rfloor \leq y < \lfloor y \rfloor + 1 \).

2. The estimation procedure

For estimating the regression function \( m \), the idea consists in writing \( m \) as the ratio
\[
m(x) = \frac{m(x) f_X(x)}{f_X(x)}, \quad x \in [0, 1]^d.
\]
In the sequel, we denote
\[
p(x) := m(x) \times f_X(x).
\]
First, we estimate \( p \), then \( f_X \). Since estimating \( f_X \) is a classical deconvolution problem, the main task consists in estimating \( p \). We propose a wavelet-based procedure with an automatic choice of the maximal resolution level. Section 2.2 describes the construction of the projection kernel on wavelet bases depending on a maximal resolution level. Section 2.3 describes the Goldenshluger-Lepski procedure to select the resolution level adaptively.

2.1. Technical conditions

To facilitate the presentation, we collect in this subsection all the conditions that we need throughout the paper.
First, some conditions are imposed on the regression function $m$ and the design density $f_X$. We suppose that

$$ m \in \mathcal{M}(m) = \{S : [0,1]^d \to \mathbb{R} : \|S\|_{\infty} \leq m\}, \quad m > 0, \quad (1) $$

and

$$ f_X \in \mathcal{M}(d) = \{f \text{ density on } [0,1]^d \text{ and } \|f\|_{\infty} \leq d\}, \quad d > 0. \quad (2) $$

Furthermore, there exists $C_1 > 0$ such that for any $x \in [0,1]^d$, $f_X(x) \geq C_1$.

To ensure the existence of all Fourier transforms, we also suppose that $m \cdot f_X$ and $\mathcal{F}(m \cdot f_X) \in L_1(\mathbb{R}^d)$.

To derive rates of convergence and lower bounds as we have to face a deconvolution step, we need some assumptions on the smoothness of the density of the errors covariates $g$. We suppose that

$$ \mathcal{F}(g)(t) = \prod_{l=1}^{d} \mathcal{F}(g_l)(t_l), $$

and there exist positive constants $c_g$ and $C_g$ such that

$$ c_g(1 + |t_l|)^{-\nu} \leq |\mathcal{F}(g_l)(t_l)| \leq C_g(1 + |t_l|)^{-\nu}, \quad \nu \geq 0, \quad t_l \in \mathbb{R}. \quad (3) $$

The left hand side of the above inequality is usual when proving upper bounds. But here as we use compactly supported wavelets, we also need the right hand side to prove upper bounds. This supplementary assumption has been already used in deconvolution density estimation problem (see [9]). The right hand side of inequality (3) also appears in the proofs of lower bounds.

We require another condition on the derivative of the Fourier transform of $g$ to prove lower bounds. There exists a positive constant $C_g$ such that

$$ |\mathcal{F}'(g_l)(t_l)| \leq C_g(1 + |t_l|)^{-\nu - 1}, \quad t_l \in \mathbb{R}. \quad (4) $$

Laplace and Gamma distributions satisfy the above Assumptions (3) and (4). Assumptions (3) and (4) control the decay of the Fourier transform of each components of $g$ at a polynomial rate controlled by the degree of ill-posedness $\nu$. Hence we deal with a midly ill-posed inverse problem.

We consider a father wavelet $\varphi$ on the real line satisfying the following conditions:

- (A1) The father wavelet $\varphi$ is compactly supported on $[-A,A]$, where $A$ is a positive integer.
- (A2) There exists a positive integer $N$, such that for any $x$

$$ \int \sum_{k \in \mathbb{Z}} \varphi(x-k)\varphi(y-k)(y-x)^\ell dy = \delta_{0\ell}, \quad \ell = 0, \ldots, N. $$

- (A3) $\varphi$ is of class $C^r$, where $r > \nu + 1$. 

Conditions (A1), (A2) and (A3) are satisfied for instance by Coiflets wavelets (see [15], Chapter 8). Condition (A3) has already been encountered in the literature (see condition (A2) in [9]). It ensures that our estimator is well-defined (more explanations about this are given in Section 2.2). Condition (A3) is also useful to prove Lemma 9.

Remark 1. Note that most of our results remain valid by using wavelets with compactly supported Fourier transform such as Meyer wavelets. However, in this case, the summation in (5) is not finite, which leads to some difficulties in practice. [9] also used compactly supported wavelets such as Daubechies ones when dealing with deconvolution density problem.

2.2. Approximation kernels and family of estimators for p

The associated projection kernel on the space

$$V_j := \text{span}\{\varphi_{jk}, k \in \mathbb{Z}^d\}, \quad j \in \mathbb{N}_d,$$

is given for any $x$ and $y$ by

$$K_j(x, y) = \sum_k \varphi_{jk}(x) \varphi_{jk}(y),$$

where for any $x$,

$$\varphi_{jk}(x) = \prod_{l=1}^d 2^{jl} \varphi(2^j x_l - k_l), \quad j \in \mathbb{N}_d, \quad k \in \mathbb{Z}^d.$$

Therefore, the projection of $p$ on $V_j$ can be written for any $z$,

$$p_j(z) := K_j(p)(z) := \int K_j(z, y)p(y)dy = \sum_k p_{jk} \varphi_{jk}(z)$$

with

$$p_{jk} = \int p(y) \varphi_{jk}(y)dy.$$

First we estimate unbiasedly projection $p_j$. Secondly to obtain the final estimate of $p$, it will remain to select a convenient value of $j$ which will be done in Section 2.3. The natural approach is based on unbiased estimation of the projection coefficients $p_{jk}$. To do so, we adapt the kernel approach proposed by [11] in our wavelets context. To this purpose, we set

$$\hat{p}_{jk} := \frac{1}{n} \sum_{u=1}^n Y_u \times (D_j \varphi)_{j,k}(W_u)$$

where

$$\frac{2^{sj}}{(2\pi)^d} \frac{1}{n} \sum_{u=1}^n Y_u \int e^{-i \langle t, 2^j W_u - k \rangle} \prod_{l=1}^d \frac{\mathcal{F}(\varphi)(t_l)}{\mathcal{F}(g_l)(2^n t_l)} dt_l,$$
then
\[ \hat{p}_j(x) = \frac{1}{n} \sum_{k} \sum_{u=1}^{n} Y_u \times (D_j \varphi)_{j,k}(W_u) \varphi_{jk}(x), \] (5)

where the deconvolution operator \( D_j \) is defined as follows for a function \( f \) defined on \( \mathbb{R}^d \):
\[ (D_j f)(w) = \frac{1}{(2\pi)^d} \int e^{-i \langle t, w \rangle} \prod_{l=1}^{d} \frac{\mathcal{F}(f)(t_l)}{\mathcal{F}(g_l)(2^n t_l)} dt, w \in \mathbb{R}^d. \] (6)

Lemma 3, proved in Section 5.2.1 states that \( E[\hat{p}_j(x)] = p_j(x) \) which justifies our approach. Note that as \( \varphi \) has compact support, the summation in \( k \) is finite for all \( x \) (see the expression of estimator \( \hat{p}_j(x) \) in (5)).

The deconvolution operator \( (D_j f)(w) \) in (6) is the multidimensional wavelet analogous of the operator \( K_n(x) \) defined in (2.4) in [11]: the Fourier transform of their kernel \( K \) has been replaced in our procedure by the Fourier transform of the wavelet \( \varphi_{jk} \) and their bandwidth \( h \) by \( 2^{-j} \). Eventually, our estimator is well-defined: using Lemma 8 and Assumption (3) we have that, for \( C \) a constant,
\[ \prod_{l=1}^{d} \left| \frac{\mathcal{F}(\varphi)(t_l)}{\mathcal{F}(g_l)(2^n t_l)} \right| \leq C \prod_{l=1}^{d} (1 + |t_l|)^{-r} (1 + 2^{2j} |t_l|)^{\nu} \leq C 2^{S_j \nu} \prod_{l=1}^{d} (1 + |t_l|)^{\nu-r}, \]
which is integrable using condition (A3).

The definition of the estimator \( \hat{p}_j(x) \) still makes sense when we do not have any noise on the variables \( X_l \) i.e \( g(x) = \delta_0(x) \) because in this case \( \mathcal{F}(g)(t) = 1 \).

2.3. Selection rule by using the Goldenshluger-Lepski methodology

The second and final step consists in selecting the multidimensional resolution level \( j \) depending on \( x \) thanks to a data-driven selection rule. This selection rule is a modification in the light of [14] of a method exposed in [18]. First we have to introduce some quantities which will intervene in the rule. In the sequel we denote for any \( w \in \mathbb{R}^d \),

\[ T_j(w) := \sum_{k} (D_j \varphi)_{j,k}(w) \varphi_{jk}(x) \]

and
\[ U_j(y, w) := y \sum_{k} (D_j \varphi)_{j,k}(w) \varphi_{jk}(x) = y \times T_j(w), \]
so we have
\[ \hat{p}_j(x) = \frac{1}{n} \sum_{u=1}^{n} U_j(Y_u, W_u). \]

Proposition 1 in Section 5.2.1 shows that \( \hat{p}_j(x) \) concentrates around \( p_j(x) \). So, the idea is to find a maximal resolution \( j \) that mimics the oracle index. The oracle
Adaptive wavelet multivariate regression with errors in variables

index minimizes a bias variance trade-off. So we have to find an estimation for the bias-variance decomposition of $\hat{p}_j(x)$. We denote $\sigma^2_j := \text{Var}(U_j(Y_1, W_1))$ and the variance of $\hat{p}_j$ is thus equal to $\frac{\sigma^2_j}{n}$. We set:

$$\hat{\sigma}^2_j := \frac{1}{n(n-1)} \sum_{l=2}^{n} \sum_{v=1}^{l-1} (U_j(Y_l, W_l) - U_j(Y_v, W_v))^2,$$

(7)

and since $E(\hat{\sigma}^2_j) = \sigma^2_j$, $\hat{\sigma}^2_j$ is a natural estimator of $\sigma^2_j$. To devise our procedure, we introduce a slightly overestimate of $\sigma^2_j$ given by:

$$\tilde{\sigma}^2_{j,\tilde{\gamma}} := \hat{\sigma}^2_j + 2C_j \sqrt{2\tilde{\gamma}\hat{\sigma}^2_j \log n \over n} + 8\tilde{\gamma}C_j^2 \log n \over n},$$

(8)

where $\tilde{\gamma}$ is a positive constant and

$$C_j := (m + s \sqrt{2\tilde{\gamma}\log n}) \|T_j\|_\infty.$$

Let $\gamma > 0$ and

$$\Gamma_\gamma(j) := \sqrt{2\gamma \tilde{\sigma}^2_{j,\tilde{\gamma}} \log n \over n} + c_j \gamma \log n \over n},$$

where

$$c_j := 16(2m + s) \|T_j\|_\infty.$$

Let

$$\Gamma_\gamma(j, j') := \Gamma_\gamma(j) + \Gamma_\gamma(j \wedge j'),$$

and

$$\Gamma^*_\gamma(j) := \sup_{j' \in J} \Gamma_\gamma(j, j').$$

(9)

We now define the selection rule for the resolution index. Let

$$\hat{R}_j := \sup_{j' \in J} \left\{ |\hat{p}_{j \wedge j'}(x) - \hat{p}_{j'}(x)| - \Gamma_\gamma(j', j) \right\} + \Gamma^*_\gamma(j).$$

(10)

Then $\hat{p}_j(x)$ is the final estimator of $p(x)$ with $\hat{j}$ such that

$$\hat{j} := \arg \min_{j \in J} \hat{R}_j,$$

(11)

where the set $J$ is defined as

$$J := \left\{ j \in \mathbb{N}^d : 2^{S_j} \leq \left\lfloor \frac{n}{\log^2 n} \right\rfloor \right\}.$$

(12)

Now, we shall highlight how the above quantities interplay in the estimation of the risk decomposition of $\hat{p}_j$. An inspection of the proof of Theorem 1 shows that a control of the bias of $\hat{p}_j$ is provided by:

$$\sup_{j' \in J} \left\{ |\hat{p}_{j \wedge j'}(x) - \hat{p}_{j'}(x)| - \Gamma_\gamma(j', j) \right\} + \Gamma^*_\gamma(j).$$
The term $|\hat{p}_{j\land j'}(x) - \hat{p}_{j'}|$ is classical when using the Goldenshluger Lepski method (see Sections 2.1 and 5.2 in [1]). Furthermore for technical reasons (see proof of Theorem 1), we do not estimate the variance of $\hat{p}_j(x)$ by $\hat{\sigma}_j^2$ but we replace it by $\Gamma_\gamma^2 (j)$. Note that we have the straightforward control

$$\Gamma_\gamma(j) \leq C \left( \tilde{\sigma}_j \sqrt{\frac{\log n}{n}} + (C_j + c_j) \frac{\log n}{\sqrt{n}} \right),$$

where $C$ is a constant depending on $\varepsilon$, $\tilde{\gamma}$ and $\gamma$. Actually we prove that $\Gamma_\gamma^2 (j)$ is of order $\frac{\log n}{n} \sigma_j^2$ (see Lemma 6 and 10). The dependence of $\tilde{\sigma}_j^2, \tilde{\gamma}$ in $m$ appears only in smaller order terms. In conclusion, up to the knowledge of $m$ and $s^2$ the procedure is completely data-driven. Next section explains how to choose the constants $\gamma$ and $\tilde{\gamma}$. Our approach is non asymptotic and based on sharp concentration inequalities.

3. Rates of convergence

3.1. Oracle inequality and rates of convergence for $p(\cdot)$

First, we state an oracle inequality which highlights the bias-variance decomposition of the risk.

**Theorem 1.** Let $q \geq 1$ be fixed and let $\hat{j}$ be the adaptive index defined as above. Then, it holds for any $\gamma > q(\nu + 1)$ and $\tilde{\gamma} > 2q(\nu + 2)$,

$$\mathbb{E} \left[ |\hat{p}_j(x) - p(x)|^q \right] \leq R_1 \left( \inf_{\eta} \mathbb{E} \left[ \left\{ B(\eta) + \Gamma_\gamma^*(\eta) \right\}^q \right] \right) + R'_1 n^{-q},$$

where

$$B(\eta) := \max \left( \sup_{j'} |\mathbb{E} [\hat{p}_{\eta \land j'}(x)] - \mathbb{E} [\hat{p}_j(x)]|, |\mathbb{E} [\hat{p}_{\eta}(x)] - p(x)| \right)$$

$R_1$ a constant depending only on $q$ and $R'_1$ a constant depending on $s$, $m$, $d$, $\varphi$, $c_g, C_g$.

The oracle inequality in Theorem 1 illustrates a bias-variance decomposition of the risk. The term $B(\eta)$ is a bias term. Indeed, one recognizes on the right side the classical bias term

$$|\mathbb{E} [\hat{p}_{\eta}(x)] - p(x)| = |p_{\eta}(x) - p(x)|.$$

Concerning $|\mathbb{E} [\hat{p}_{\eta \land j'}(x)] - \mathbb{E} [\hat{p}_j(x)]|$, for sake of clarity let us consider for instance the univariate case: if $j' \leq \eta$ this term is equal to zero. If $j' \geq \eta$, it turns to be

$$|\mathbb{E} [\hat{p}_{\eta}(x)] - \mathbb{E} [\hat{p}_j(x)]| = |p_{\eta}(x) - p_j(x)| \leq |p_{\eta}(x) - p(x)| + |p_j(x) - p(x)|.$$
As we have the following inclusion for the projection spaces $V_\eta \subset V_j'$, the term $p_j'$ is closer to $p$ than $p_\eta$ for the $L_2$-distance. Hence we expect a good control of $|p_j'(x) - p(x)|$ with respect to $|p_\eta(x) - p(x)|$. Finally, the third term is a remainder and is negligible.

We study the rates of convergence of the estimators over anisotropic Hölder classes which are adapted to local estimation. Let us define them.

**Definition 1** (Anisotropic Hölder Space). Let $\vec{\beta} = (\beta_1, \beta_2, \ldots, \beta_d) \in (\mathbb{R}_+)^d$ and $L > 0$. We say that $f : [0, 1]^d \to \mathbb{R}$ belongs to the anisotropic Hölder class $\mathbb{H}_d(\vec{\beta}, L)$ of functions if $f$ is bounded and for any $l = 1, \ldots, d$ and for all $z \in \mathbb{R}$

$$
\sup_{x \in [0, 1]^d} \frac{\partial^{\lfloor \beta_l \rfloor} f}{\partial x_l^{\lfloor \beta_l \rfloor}} (x_1, \ldots, x_l + z, \ldots, x_d) - \frac{\partial^{\lfloor \beta_l \rfloor} f}{\partial x_l^{\lfloor \beta_l \rfloor}} (x_1, \ldots, x_l, \ldots, x_d) \leq L |z|^{\beta_l - \lfloor \beta_l \rfloor}.
$$

The following theorem gives the rate of convergence of the estimator $\hat{p}_j(x)$ for the pointwise $L_q$ risk with $q \geq 1$. Of course, one gets the usual pointwise $L_2$ risk for $q = 2$.

**Theorem 2.** Let $q \geq 1$ be fixed and let $\hat{j}$ be the adaptive index defined in (11). Then, if for any $l$, $\lfloor \beta_l \rfloor \leq N$ and $L > 0$, it holds

$$
\sup_{p \in \mathbb{H}_d(\vec{\beta}, L)} \mathbb{E} \left| \hat{p}_{\hat{j}}(x) - p(x) \right|^q \leq L \frac{q(2s+1)}{2s+1} R_2 \left( \frac{\log n}{n} \right)^{q\tilde{\beta}/(2\tilde{\beta}+2s+1)},
$$

with $\tilde{\beta} = \frac{1}{\beta_1 + \cdots + \frac{1}{\beta_d}}$ and $R_2$ a constant depending on $\gamma, q, \tilde{\gamma}, \tilde{m}, \rho, s, \varphi, \epsilon_g, C_g, \vec{\beta}$.

**Remark 2.** The estimate $\hat{p}_{\hat{j}}(x)$ achieves the optimal rate of convergence up to a logarithmic term (see Section 3.3 in [4]). This logarithmic loss is due to adaptation.

The next section presents convergence rates for the estimator $\hat{m}(x)$ of the regression function $m$.

### 3.2. Rates of convergence for $m(\cdot)$

As mentioned above, the estimation of $m$ requires an adaptive estimate of $f_X$. This is due to kernel estimators, e.g. projection estimators do not need the additional estimate (see [1]). For this purpose, we use an estimate introduced by [4] (Section 3.4) denoted by $\hat{f}_X$. This estimate is constructed from a deconvolution kernel and the bandwidth is selected via a method described in [14]. We will not give the explicit expression of $\hat{f}_X$ for ease of exposition. Then, we define the estimate of $m$ for all $x \in [0, 1]^d$

$$
\hat{m}(x) = \frac{\hat{p}_{\hat{j}}(x)}{\hat{f}_X(x) \lor n^{-1/2}}.
$$

The term $n^{-1/2}$ is added to avoid the drawback when $\hat{f}_X$ is closed to 0.
Theorem 3. Let \( q \geq 1 \) be fixed and let \( \hat{m} \) defined as above. Then, if for any \( l, \lfloor \beta l \rfloor \leq N \) and \( L > 0 \), it holds

\[
\sup_{(m,f_X) \in \mathbb{H}_d(\vec{\beta},L) \times \mathbb{H}_d(\vec{\beta},L)} \mathbb{E} |\hat{m}(x) - m(x)|^q \leq L^{q(2\nu+1)/\beta + 2\nu + 1} R_3 \left( \frac{\log n}{n} \right)^{q\beta/(2\beta + 2\nu + 1)},
\]

with \( R_3 \) a constant depending on \( \gamma, q, \tilde{\gamma}, m, s, \varphi, c_g, C_g, \vec{\beta} \).

The following theorem gives a lower bound for the pointwise risk:

Theorem 4. Let \( q \geq 1, L > 0 \) and for any \( l, |\beta l| \leq N \). Then for any estimator \( \hat{m} \) of \( m \) and for \( n \) large enough we have

\[
\sup_{(m,f_X) \in \mathbb{H}_d(\vec{\beta},L) \times \mathbb{H}_d(\vec{\beta},L)} \mathbb{E} |\hat{m}(x) - m(x)|^q \geq R_4 n^{q\beta/(2\beta + 2\nu + 1)},
\]

with \( R_4 \) a positive constant depending on \( \vec{\beta}, L, s, C_g \) and \( C_g \).

Consequently, the estimate \( \hat{m} \) achieves the optimal rate of convergence up to a logarithmic term and oracle inequality derived in Theorem 1 is then optimal.

4. Numerical results

In this section, we implement some simulations to illustrate the theoretical results. We aim at estimating the Doppler regression function \( m \) at two points \( x_0 = 0.25 \) and \( x_0 = 0.90 \) (see Figure 1). We have \( n = 1024 \) observations and the regression errors \( \varepsilon_i \)'s follow a standard normal density with variance \( s^2 = 0.15^2 \). As for the design density of the \( X_i \)'s, we consider the Beta density and the uniform density on \([0, 1]\). The uniform distribution is quite classical in regression with random design. The \( \text{Beta}(2, 2) \) and \( \text{Beta}(0.5, 2) \) distributions reflect two very different behaviors on \([0, 1]\). Indeed, we recall that the Beta density with parameters \((a, b)\) (denoted here by \( \text{Beta}(a, b) \)) is proportional to \( x^{a-1}(1-x)^{b-1}1_{[0,1]}(x) \). Moreover, despite the fact that Beta densities vanish in

![Fig 1](image-url)
0 and 1 and the design density $f_X$ is assumed to be bounded from below, the choice of Beta distributions is still reasonable for simulations on any compact strictly included into $[0, 1]$. Our numerical study illustrates the deteriorated performances of the estimator at points very close to 0 and 1. This is justified in Table 3.

In Figure 2, we plot the noisy regression Doppler function according to the three design scenario. For the covariate errors $\delta_i$’s, we focus on the centered Laplace density with scale parameter $\sigma_{gL} > 0$ that we denote $gL$. This latter has the following expression:

$$gL(x) = \frac{1}{2\sigma_{gL}} e^{-\frac{|x|}{\sigma_{gL}}}.$$ 

The choice of the centered Laplace noise is motivated by the fact that the Fourier transform of $gL$ is given by

$$\mathcal{F}(gL)(t) = \frac{1}{1 + \sigma_{gL}^2 t^2},$$

and according to Assumption (3), it gives an example of an ordinary smooth noise with degree of ill-posedness $\nu = 2$. Furthermore, when facing regression problems with errors in the design, it is common to compute the so-called reliability ratio (see [11]) which is given by

$$R_r := \frac{\text{Var}(X)}{\text{Var}(X) + 2\sigma^2_{gL}}.$$ 

$R_r$ permits to assess the amount of noise in the covariates. The closer to 0 $R_r$ is, the bigger the amount of noise in the covariates is and the more difficult the deconvolution step will be. For instance, [11] chose $R_r = 0.70$. We computed the reliability ratio in Table 1 for the considered simulations.

We recall that our estimator of $m(x)$ is given by the ratio of two estimators (see (13)):

$$\hat{m}(x) = \frac{\hat{p}_j(x)}{f_X(x) \vee n^{-1/2}}. \quad (14)$$
First, we compute \( \hat{p}_j(x) \) an estimator of \( p(x) = m(x) \times f_X(x) \) which is denoted “GL” in the graphics below. We use coiflet wavelets of order 5. Then we divide \( \hat{p}_j(x) \) by the adaptive deconvolution density estimator \( \hat{f}_X(x) \) of [4]. This latter is constructed with a deconvolution kernel and an adaptive bandwidth. For the selection of the coiflet level \( j \) in \( \hat{p}_j(x) \), we advise to use \( \hat{\sigma}_j^2 \) instead of \( \tilde{\sigma}_j^2 \), \( \tilde{\gamma} \) and \( 2^{\max_i \sum_i |Y_i|} \) instead of \( c_j \). It remains to settle the value of the constant \( \gamma \). To do so, we compute the pointwise risk of \( \hat{p}_j(x) \) in function of \( \gamma \): Figure 3 shows a clear "dimension jump" and accordingly the value \( \gamma = 0.5 \) turns to be reasonable. Hence we fix \( \gamma = 0.5 \) for all simulations and our selection rule is completely data-driven.

**Table 1**

| \( \sigma_{\text{GL}} \) | Design of the \( X_i \) |
|------------------------|-----------------|
| \( 0.075 \)         | \( U[0,1] \)   | \( \beta(2,2) \) | \( \beta(0.5,2) \) |
| \( 0.10 \)          | \( 0.88 \)     | \( 0.81 \)     | \( 0.80 \)     |

![Figure 3. Pointwise risk of \( \hat{p}_j \) at \( x_0 = 0.25 \) in function of parameter \( \gamma \) for the \( \beta(2,2) \) design and \( \sigma_{\text{GL}} = 0.075 \).](image-url)
the performances to be better near 0 as the observations tend to concentrate near 0 and to be bad close to 1. Indeed, this phenomenon is confirmed by Table 3. And when comparing the $\text{Beta}(2, 2)$ and $\text{Beta}(0.5, 2)$ distributions, the performances are much better for the $\text{Beta}(0.5, 2)$ at $x_0 = 0.25$ whereas the $\text{Beta}(2, 2)$ distribution yields better results at $x_0 = 0.90$. This is what is
### Table 2

MAE of $\hat{m}(x)$: on the left at $x_0 = 0.25$ and on the right $x_0 = 0.90$.

| $\sigma_{gL}$ | design of the $X_i$ | | $\sigma_{gL}$ | design of the $X_i$ |
|--------------|-------------------|---|--------------|-------------------|
|              | $U[0,1]$ Beta(2,2) | |              | $U[0,1]$ Beta(0.5, 2) |
| 0.075        | 0.0144            | 0.0204 | 0.0071     | 0.075             |
| 0.10         | 0.0156            | 0.0206 | 0.0072     | 0.10              |
| 0.075        | 0.0212            | 0.0177 | 0.1012     |                   |
| 0.10         | 0.0192            | 0.0195 | 0.104      |                   |

### Table 3

MAE of $\hat{m}(x)$ at the points very close to 0 and 1: on the left: $x_0 = 0.01$ and on the right: $x_0 = 0.98$.

| $\sigma_{gL}$ | design of the $X_i$ | | $\sigma_{gL}$ | design of the $X_i$ |
|--------------|-------------------|---|--------------|-------------------|
|              | $U[0,1]$ Beta(2,2) | |              | $U[0,1]$ Beta(0.5, 2) |
| 0.075        | 0.3461            | 0.5312 | 0.3445     | 0.075             |
| 0.10         | 0.3668            | 0.5493 | 0.3589     | 0.10              |
| 0.075        | 0.2153            | 0.3429 | 0.5130     |                   |
| 0.10         | 0.2191            | 0.3453 | 0.5293     |                   |

expected as the two densities charge points near 0 and 1 differently.

For our simulations, we have chosen coiflets of order $K = 5$. The Fourier transform for the coiflet $\varphi$ is given by:

$$F(\varphi)(t) = \int_\mathbb{R} \exp(-itx)\varphi(x)dx, \quad t \in \mathbb{R}. $$

In theory, the Fourier transform is defined for all $t \in \mathbb{R}$. But in practice, it is sufficient to select $t \in [-L, L]$ since $F(\varphi)(t)$ almost vanishes for all $t$ outside the interval $[-L, L]$ where $L$ is chosen to be large enough. Preliminary simulations allowed us to select $L = 50$ and we partitioned the interval $[-L, L]$ into $M = 4096$ points $t_k = -L + k\Delta t, \; k = 0, \ldots, M - 1$ with $\Delta t = 2L/(M - 1)$. Then we approximated $F(\varphi)(t_k)$ by a Riemann sum:

$$F(\varphi)(t_k) \approx \sum_{j=0}^{N-1} \exp(-it_k x_j)\varphi(x_j)\Delta x. $$

Since the support of the coiflet $\varphi$ is $[-2K, 4K - 1]$, we approximated $F(\varphi)(t_k)$ on the grid $[x_0, x_1, \ldots, x_{N-1}]$ where $x_j = -2K + j\Delta x, \; j = 0, \ldots, N - 1$ and $\Delta x = (6K - 1)/(N - 1), \; N = 2048$.

In a similar way, we approximated the integral

$$(D_j\varphi)(w) = \int_\mathbb{R} \exp(-iwt) \frac{F(\varphi)(t)}{F(g_L)(2^j t)} dt, \quad w \in \mathbb{R},$$

by

$$\sum_{k=0}^{M-1} \exp(-it_k w) \left(1 + \sigma^2_{g_L} (2^j t_k)^2\right) F(\varphi)(t_k) \Delta t,$$

since $F(g_L)(t) = 1/(1 + \sigma^2_{g_L} t^2)$ by the choice of the centered Laplace noise.
5. Proofs

5.1. Proofs of theorems

This section is devoted to the proofs of theorems. These proofs use some propositions and technical lemmas which are respectively in Section 5.2.1 and 5.2.2. In the sequel, C is a constant which may vary from one line to another one.

5.1.1. Proof of Theorem 1

Proof. We firstly recall the basic inequality \((a_1 + \cdots + a_p)^q \leq p^{q-1}(a_1^q + \cdots + a_p^q)\) for all \(a_1, \ldots, a_p \in \mathbb{R}_+^p, p \in \mathbb{N} \text{ and } q \geq 1\). For ease of exposition, we denote \(\hat{p}_j(x) = \hat{p}_j\). So, we can show for any \(\eta \in \mathbb{N}^d\):

\[
\begin{align*}
\left| \hat{p}_j - p(x) \right| &\leq \left| \hat{p}_j - \hat{p}_{j\Lambda} \right| + \left| \hat{p}_{j\Lambda} - \hat{p}_n \right| + \left| \hat{p}_n - p(x) \right| \\
&\leq \left| \hat{p}_{\eta \wedge j} - \hat{p}_j \right| - \Gamma_\gamma(j, \eta) + \Gamma_\gamma(j, \eta) + \left| \hat{p}_{j\Lambda} - \hat{p}_n \right| \\
&\quad - \Gamma_\gamma(j, \eta) + \Gamma_\gamma(j, \eta) + \left| \hat{p}_n - p(x) \right| \\
&\leq \left| \hat{p}_{\eta \wedge j} - \hat{p}_j \right| - \Gamma_\gamma(j, \eta) + \Gamma_\gamma(j, \eta) + \left| \hat{p}_{j\Lambda} - \hat{p}_n \right| \\
&\quad - \Gamma_\gamma(j, \eta) + \Gamma_\gamma(j, \eta) + \left| \hat{p}_n - p(x) \right| \\
&\leq \hat{R}_\eta + \hat{R}_j + \left| \hat{p}_n - p(x) \right| \\
&\leq \hat{R}_\eta + \hat{R}_j + |E[\hat{p}_n] - p(x)| + |\hat{p}_n - E[\hat{p}_n]| \\
&\leq \hat{R}_\eta + \hat{R}_j + |E[\hat{p}_n] - p(x)| + |\hat{p}_n - E[\hat{p}_n]| - \Gamma_\gamma(\eta) + \Gamma_\gamma(\eta) \\
&\leq \hat{R}_\eta + \hat{R}_j + \left| E[\hat{p}_n] - p(x) \right| + \sup_{j'} \left\{ |\hat{p}_{j'} - E[\hat{p}_{j'}]| - \Gamma_\gamma(j') \right\}_+ + \Gamma_\gamma(\eta).
\end{align*}
\]

By definition of \(\hat{j}\), we recall that \(\hat{R}_j \leq \inf_{\eta} \hat{R}_\eta\) and

\[
\hat{R}_\eta \leq \sup_{j, j'} \left\{ |\hat{p}_{j \wedge j'} - E[\hat{p}_{j \wedge j'}]| - \Gamma_\gamma(j \wedge j') \right\}_+ + \sup_{j'} \left\{ |\hat{p}_{j'} - E[\hat{p}_{j'}]| - \Gamma_\gamma(j') \right\}_+ + \sup_{j'} |E[\hat{p}_{\eta \wedge j'}] - E[\hat{p}_{j'}]| + \Gamma_\gamma(\eta).
\]

Hence

\[
\begin{align*}
\left| \hat{p}_j - p(x) \right| &\leq 2 \left[ \sup_{j, j'} \left\{ |\hat{p}_{j \wedge j'} - E[\hat{p}_{j \wedge j'}]| - \Gamma_\gamma(j \wedge j') \right\}_+ \\
&\quad + \sup_{j'} \left\{ |\hat{p}_{j'} - E[\hat{p}_{j'}]| - \Gamma_\gamma(j') \right\}_+ + \sup_{j'} |E[\hat{p}_{\eta \wedge j'}] - E[\hat{p}_{j'}]| \right]
\end{align*}
\]
+ 2\Gamma^*_\gamma(\eta) + |E[\hat{p}_\eta] - p(x)| + \sup_{j' \in J} \left\{ |\hat{p}_{j'} - E[\hat{p}_{j'}]| - \Gamma_\gamma(j') \right\}_+ + \Gamma^*_\gamma(\eta).

By definition of \( B(\eta) = \max \left( \sup_{j' \in J} |E[\hat{p}_{\eta \wedge j'}] - E[\hat{p}_{j'}]|, |E[\hat{p}_\eta] - p(x)| \right) \), we get

\[
|\hat{p}_j - p(x)| \leq 2\sup_{j,j'} \left\{ |\hat{p}_{j \wedge j'} - E[\hat{p}_{j \wedge j'}]| - \Gamma_\gamma(j \wedge j') \right\}_+ + 3\sup_{j,j'} \left\{ |\hat{p}_{j'} - E[\hat{p}_{j'}]| - \Gamma_\gamma(j') \right\}_+ + \Gamma^*_\gamma(\eta).
\]

Consequently

\[
|\hat{p}_j - p(x)|^q \leq 3^{2q-1} \left( [B(\eta) + \Gamma^*_\gamma(\eta)]^q + \sup_{j'} \left( |\hat{p}_{j'} - E[\hat{p}_{j'}]| - \Gamma_\gamma(j') \right)^q_+ + \sup_{j,j'} \left( |\hat{p}_{j \wedge j'} - E[\hat{p}_{j \wedge j'}]| - \Gamma_\gamma(j \wedge j') \right)^q_+ \right).
\]

Using Proposition 2, we have

\[
E \left[ |\hat{p}_j - p(x)|^q \right] \leq C \left( E \left[ (B(\eta) + \Gamma^*_\gamma(\eta))^q \right] \right) + R'_1 n^{-q}.
\]

Then, we get

\[
E \left[ |\hat{p}_j - p(x)|^q \right] \leq R_1 \left( \inf_{\eta} E \left[ (B(\eta) + \Gamma^*_\gamma(\eta))^q \right] \right) + R'_1 n^{-q},
\]

where \( R_1 \) is a constant only depending on \( q \) and \( R'_1 \) a constant depending on \( m, d, s, \varphi, c_g, C_g \). \( \square \)

5.1.2. Proof of Theorem 2

\textbf{Proof.} The proof is a direct application of Theorem 1 together with a standard bias-variance trade-off. We first recall the assertion of this theorem:

\[
E \left[ |\hat{p}_j(x) - p(x)|^q \right] \leq C \left( \inf_{\eta} E \left[ (B(\eta) + \Gamma^*_\gamma(\eta))^q \right] \right) + R'_1 n^{-q}.
\]

For the bias term, we use Proposition 3 to get:

\[
B(\eta) \leq CL \sum_{i=1}^d 2^{-m \beta_i}, \text{for all } \eta \in J.
\]

Now let us focus on \( E \left[ \Gamma^*_\gamma(\eta)^q \right] \). We have

\[
E \left[ \Gamma^*_\gamma(\eta)^q \right] = E \left[ \left( \sqrt{\frac{2\gamma(1+\varepsilon)\tilde{\sigma}_2^2 \log n}{n} + \frac{c_{d \gamma} \log n}{n}} \right)^q \right]
\]
Adaptive wavelet multivariate regression with errors in variables

\[ \leq 2^{q-1} \left( \frac{2\gamma (1 + \epsilon) \log n}{n} \right)^{\frac{q}{2}} \mathbb{E}[\tilde{\sigma}_m^q] + \left( c_n \frac{\log n}{n} \right)^q \]

\[ \leq C \left( \left( \frac{\log n}{n} \right)^{\frac{q}{2}} 2(2S_n^{\nu} + S_n) \frac{q}{2} + \left( c_n \frac{\log n}{n} \right)^q \right), \]

using Lemma 6. But

\[ c_n = 16 \left( 2m + s \right) \| T_n \|_{\infty} \leq C 2S_n^{\nu} + S_n, \]

using Lemma 10. Hence

\[ \mathbb{E} \left[ \Gamma_\gamma (\eta)^q \right] \leq C \left( \left( \frac{\log n}{n} \right)^{\frac{q}{2}} 2(2S_n^{\nu} + S_n + \sqrt{2}) \frac{q}{2} + \left( c_n \frac{\log n}{n} \right)^q \right), \]

We have

\[ \left( \frac{\log n}{n} \right)^{\frac{q}{2}} 2(2S_n^{\nu} + S_n) \frac{q}{2} \geq \left( \frac{\log n}{n} \right)^q 2(S_n^{\nu} + S_n) \Longleftrightarrow 2S_n \leq \frac{n}{\log n}, \]

which is true since by (12), \( 2S_n \leq \frac{\log n}{\log (\log n)} \).

This yields

\[ \mathbb{E} \left[ \Gamma_\gamma^* (\eta)^q \right] \leq C \left( \left( \frac{\log n}{n} \right)^{\frac{q}{2}} \frac{2(2S_n^{\nu} + S_n)}{n} \right)^q. \]

Eventually, we obtain the bound for the pointwise risk:

\[ \mathbb{E} \left[ \hat{p}_j (x) - p(x) \right]^q \leq C \left( \inf_{\eta} \left\{ L \sum_{l=1}^d 2^{-n_l \eta_l} + \sqrt{\frac{2(2S_n^{\nu} + S_n)}{n} \log (n)} \right\} \right)^q + R_1 n^{-q}. \]

Setting the gradient of the right hand side of the inequality above with respect to \( \eta \), it turns out that the optimal \( \eta_l \) is proportional to \( \frac{1}{\log (\log (n))} \), which leads for \( n \) large enough to

\[ \mathbb{E} \left[ \hat{p}_j (x) - p(x) \right]^q \leq L \frac{\phi_q(2\nu + 1)}{n^{2\nu + 2 + 1}} R_2 \frac{\log (n)}{n^{2\nu + 2 + 1}}, \]

with \( R_2 \) a constant depending on \( \gamma, q, \tilde{\gamma}, m, s, \delta, \varphi, c_\gamma, c_\tilde{\gamma}, \beta. \) The proof of Theorem 2 is completed.

5.1.3. Proof of Theorem 3

Proof. We recall that \( m(x) = \frac{p(x)}{f_X(x)} \) and \( \hat{m}(x) = \frac{\hat{p}_j(x)}{f_X(x)^{1/(2\nu + 1)}} \). We now state the main properties of the adaptive estimate \( \hat{f}_X \) showed by [4] (Theorem 2): for all \( q \geq 1 \), all \( \beta \in (0, 1]^d \), all \( L > 0 \) and \( n \) large enough, it holds

\[ \mathbb{P} (E_1) := \mathbb{P} (|\hat{f}_X (x) - f_X (x)| \geq C \phi_n (\beta)) \leq n^{-2q}, \]

(15)
and
\[ \mathbb{P}\left( \left| \hat{f}_X(x) - f_X(x) \right| \leq Cn \right) = 1, \]
where \( \phi_n(\beta) := (\log(n)/n)^{\beta/(2\beta + 2\nu + 1)} \). Although the construction of the estimate \( \hat{f}_X(x) \) depends on \( q \), we remove the dependency for ease of exposition (see [4] Section 3.4 for further details). From (15), we easily deduce, since \( f_X(x) \geq C_1 > 0 \), for \( n \) large enough that
\[ \mathbb{P}\left( E_2 \right) := \mathbb{P}\left( \hat{f}_X(x) < \frac{C_1}{2} \right) \leq n^{-2q}. \]
We now start the proof of the theorem. We have together with (16)
\[ |\hat{m}(x) - m(x)| = \left| \frac{\hat{p}_j(x)}{\hat{f}_X(x) \lor n^{-1/2}} - \frac{p(x)}{f_X(x)} \right| \]
\[ \leq \left| \frac{\hat{p}_j(x)}{\hat{f}_X(x) \lor n^{-1/2}} - \frac{p(x)}{f_X(x) \lor n^{-1/2}} \right| + \left| \frac{p(x)}{f_X(x) \lor n^{-1/2}} - \frac{p(x)}{f_X(x)} \right| \]
\[ \leq \frac{\hat{p}_j(x) - p(x)}{f_X(x) \lor n^{-1/2}} + \|m\|\|f_X\| \left| \frac{\hat{f}_X(x) \lor n^{-1/2}}{f_X(x) \lor n^{-1/2}} - \frac{f_X(x)}{f_X(x)} \right| \]
\[ := A_1 + ||m||\|f_X\|A_2. \]

**Control of** \( \mathbb{E}[A_1^q] \). Using Cauchy-Schwarz inequality and the inequality \( \hat{f}_X(x) \lor n^{-1/2} \geq n^{-1/2} \), we obtain for \( n \) large enough
\[ \mathbb{E}[A_1^q] = \mathbb{E}[A_1^q 1_{E_2}] + \mathbb{E}[A_1^q 1_{E_2}^c] \]
\[ \leq \mathbb{E}[A_1^q 1_{E_2}] + \sqrt{\mathbb{E}[A_1^{2q}]} \sqrt{\mathbb{P}(E_2)} \]
\[ \leq C\mathbb{E} \left[ \left| \hat{p}_j(x) - p(x) \right|^q \right] + n^{q/2} \sqrt{\mathbb{E} \left[ \left| \hat{p}_j(x) - p(x) \right|^{2q} \right]} \sqrt{\mathbb{P}(E_2)}. \]

Then, using Theorem 2 and (17), we finally have \( \mathbb{E}[A_1^q] \leq C\phi_n^q(\beta) \).

**Control of** \( \mathbb{E}[A_2^q] \). Using (16) and the inequality \( \hat{f}_X(x) \lor n^{-1/2} \geq n^{-1/2} \), it holds for \( n \) large enough
\[ \mathbb{E}[A_2^q] \leq \mathbb{E}[A_2^q 1_{E_2}] + \mathbb{E}[A_2^q 1_{E_2}^c] \]
\[ \leq \mathbb{E}[A_2^q 1_{E_2}] + Cn^{q/2} (\mathbb{P}(E_1) + \mathbb{P}(E_2)). \]

Then, using the definition of \( A_2 \), (15) and (17), we obtain \( \mathbb{E}[A_2^q] \leq C\phi_n^q(\beta) \).

Eventually, by definitions of \( A_1 \) and \( A_2 \), the proof is completed and
\[ \mathbb{E}[|\hat{m}(x) - m(x)|^q] \leq C(\mathbb{E}[A_1^q] + \mathbb{E}[A_2^q]) \leq L\frac{\gamma(\gamma + 1)}{\gamma + 1} R_3 \left( \frac{\log(n)}{n} \right)^{q\beta/(2\beta + 2\nu + 1)} \]
where \( R_3 \) is a constant depending on \( \gamma, q, \gamma, m, s, \delta, \varphi, \gamma, C_1, \gamma, \beta \). This completes the proof of Theorem 3. \( \square \)
5.1.4. Proof of Theorem 4

Following Meister [21], the proof is straightforward. Indeed, for the regression problem with errors in variables, Theorem 3.5 in [21] proves a lower bound in probability for the pointwise risk which claims that the minimax rate in dimension 1 is \( n^{-\frac{2\beta}{2\beta + 1}} \) for Hölder class of index \( \beta \) and noise degree-of-ill-posedness parameter \( \nu \). Following step by step the proof of Theorem 3.5 in [21] in dimension 2 (the extension to general case can be easily deduced), one obtains the lower bound of Theorem 4. In fact, Meister uses densities such as Cauchy distributions which admit multivariate counterparts.

5.2. Statements and proofs of auxiliary results

This section is devoted to statements and proofs of auxiliary results used in Section 5.1.

5.2.1. Statements and proofs of propositions

Let us start with Proposition 1 which states a concentration inequality of \( \hat{p}_j \) around \( p_j \).

**Proposition 1.** Let \( j \) be fixed. For any \( u > 0 \),

\[
P \left( \left| \hat{p}_j(x) - p_j(x) \right| \geq \sqrt{\frac{2\sigma_j^2}{n}} + \frac{c_j u}{n} \right) \leq 2e^{-u},
\]

(18)

where

\[ \sigma_j^2 = \text{Var}(Y_Tj(W)). \]

For any \( \tilde{\gamma} > 1 \) we have for any \( \tilde{\varepsilon} > 0 \) that there exists \( R_4 \) only depending on \( \tilde{\gamma} \) and \( \tilde{\varepsilon} \) such that

\[ \mathbb{P}(\sigma_j^2 \geq (1 + \tilde{\varepsilon})\sigma_{j,\tilde{\gamma}}^2) \leq R_4 n^{-\tilde{\gamma}}, \]

\( \sigma_{j,\tilde{\gamma}}^2 \) being defined in (8).

**Proof.** First, note that

\[ \hat{p}_j(x) = \sum_k \hat{p}_{jk} \varphi_{jk}(x) = \frac{1}{n} \sum_{l=1}^n Y_l \sum_k (D_j \varphi)_{j,k}(W_l) \varphi_{jk}(x) = \frac{1}{n} \sum_{l=1}^n U_j(Y_l, W_l). \]

To prove Proposition 1, we apply the Bernstein inequality to the variables \( U_j(Y_l, W_l) - \mathbb{E}[U_j(Y_l, W_l)] \) that are independent. Since, \( U_j(Y_l, W_l) = Y_l T_j(W_l) \), and \( \mathbb{E}[\varepsilon_i T_j(W_l)] = 0, \)
we have for any $q \geq 2$,

$$A_q := \sum_{l=1}^{n} E[|U_j(Y_l, W_l) - E[U_j(Y_l, W_l)]|^q]$$

$$= \sum_{l=1}^{n} E \left[ |m(X_l)T_j(W_l) + \epsilon_l T_j(W_l) - E[m(X_l)T_j(W_l)]|^q \right]. \quad (19)$$

With $q = 2$,

$$A_2 = \sum_{l=1}^{n} E[|U_j(Y_l, W_l) - E[U_j(Y_l, W_l)]|^2]$$

$$= n \text{Var}(Y_l T_j(W_l))$$

$$= n \mathbb{E}[(m(X_l)T_j(W_l) + \epsilon_l T_j(W_l) - E[m(X_l)T_j(W_l)])^2]$$

$$= n \mathbb{E}[\epsilon_l^2 T_j^2(W_l)] + n \text{Var}(m(X_l)T_j(W_l))$$

$$= n \left( s^2 \mathbb{E}[T_j^2(W_l)] + \text{Var}(m(X_l)T_j(W_l)) \right).$$

Now, for any $q \geq 3$, with $Z \sim \mathcal{N}(0, 1)$,

$$A_q \leq n^{2q-1} \left( \mathbb{E}[|m(X_l)T_j(W_l) - E[m(X_l)T_j(W_l)]|^q] + \mathbb{E}[|\epsilon_l T_j(W_l)|^q] \right)$$

$$\leq n^{2q-1} \left( \mathbb{E}[|m(X_l)T_j(W_l) - E[m(X_l)T_j(W_l)]|^q] + s^q \mathbb{E}[|Z|^q|E[T_j^2(W_l)]|] \right)$$

$$\leq n^{2q-1} \left( \mathbb{E}[|m(X_l)T_j(W_l) - E[m(X_l)T_j(W_l)]|^q] + s^q \mathbb{E}[|Z|^q|E[T_j^2(W_l)]|] \right)$$

$$+ s^q \mathbb{E}[|Z|^q|E[T_j^2(W_l)]|] \mathbb{E}[T_j^2(W_l)] \| T_j \|_\infty^2.$$

Furthermore,

$$\mathbb{E}[|m(X_l)T_j(W_l) - E[m(X_l)T_j(W_l)]|^q]$$

$$\leq \mathbb{E}[|m(X_l)T_j(W_l) - E[m(X_l)T_j(W_l)]|^2] \times (2 \| m \|_\infty \| T_j \|_\infty)^{q-2}$$

$$= \text{Var}(m(X_l)T_j(W_l)) \times (2 \| m \|_\infty \| T_j \|_\infty)^{q-2}.$$

Finally,

$$A_q \leq n^{2q-1} \| T_j \|_\infty^{q-2} \left( \mathbb{E}[\text{Var}(m(X_l)T_j(W_l)) \times (2 \| m \|_\infty)^{q-2} + s^q \mathbb{E}[|Z|^q|E[T_j^2(W_l)]|] \right)$$

$$\leq n^{2q-1} \| T_j \|_\infty^{q-2} \mathbb{E}[|Z|^q] \left( \mathbb{E}[\text{Var}(m(X_l)T_j(W_l)) \times (2 \| m \|_\infty)^{q-2} + s^q \mathbb{E}[T_j^2(W_l)] \right)$$

$$\leq n^{2q-1} \| T_j \|_\infty^{q-2} \mathbb{E}[|Z|^q] \times A_2 \times (2 \| m \|_\infty)^{q-2} + s^{q-2}$$

$$\leq 2 \| T_j \|_\infty^{q-2} \mathbb{E}[|Z|^q] \times A_2 \times (2 \| m \|_\infty + s)^{q-2}.$$

Besides we have (see page 23 in [22]) denoting $\Gamma$ the Gamma function

$$\mathbb{E}[|Z|^q] = \frac{\Gamma(q/2)}{\sqrt{\pi}} \left( \frac{q+1}{2} \right) \leq 2^{q/2} 2^{-1/2} q! \leq 2^{(q-1)/2} q!,$$  \quad (20)
as \( \frac{1}{\sqrt{\pi}} \leq \frac{1}{\sqrt{2}} \) and \( \Gamma(\frac{2q+1}{2}) \leq \Gamma(q+1) = q! \). So, for \( q \geq 3 \),

\[
A_q \leq 2^{q-1} \cdot \|T_j\|_\infty^\frac{q-2}{2} q! \cdot A_2 \cdot (2\|m\|_\infty + s)^{q-2}
\]

\[
\leq \frac{q!}{2} \cdot A_2 \cdot \left( 2 \cdot \frac{q-1}{2(q-2)} \cdot \|T_j\|_\infty \cdot (2\|m\|_\infty + s) \right)^{q-2},
\]

The function \( \frac{3q-1}{2(q-2)} \) is decreasing in \( q \). Hence for any \( q \geq 3 \), \( 2^{\frac{3q-1}{2(q-2)}} \leq 16 \).

Thus

\[
A_q \leq \frac{q!}{2} \cdot A_2 \cdot c_j^{q-2},
\]

with

\[
c_j := 16 \|T_j\|_\infty \cdot (2m + s).
\]

We can now apply Proposition 2.9 of Massart [20]. We denote \( f_W \) the density of the \( W_l \)'s. We have

\[
\mathbb{E}[T_j^2(W_1)] = \int T_j^2(w)f_W(w)dw
\]

\[
\leq \|fx\|_\infty \cdot \|T_j\|_2^2,
\]

since the density \( f_W \) is the convolution of \( fx \) and \( g \), \( \|f_W\|_\infty = \|fx \ast g\|_\infty \leq \|fx\|_\infty \). We have

\[
\text{Var}(m(X_1)T_j(W_1)) \leq \mathbb{E}[m^2(X_1)T_j^2(W_1)]
\]

\[
\leq \|m\|_\infty^2 \int T_j^2(w)f_W(w)dw
\]

\[
\leq \|m\|_\infty^2 \cdot \|fx\|_\infty \cdot \|T_j\|_2^2.
\]

Therefore, with

\[
\sigma_j^2 = \frac{A_2}{n} = \text{Var}(Y_1T_j(W_1)),
\]

\[
\sigma_j^2 = \sigma_0^2 \mathbb{E}[T_j^2(W_1)] + \text{Var}(m(X_1)T_j(W_1))
\]

\[
\leq \sigma_0^2 \cdot \|fx\|_\infty \cdot \|T_j\|_2^2 + \|m\|^2_\infty \cdot \|fx\|_\infty \cdot \|T_j\|_2^2
\]

\[
\leq \|fx\|_\infty \cdot \|T_j\|_2^2 (s^2 + \|m\|^2_\infty).
\]

We conclude that for any \( u > 0 \),

\[
\mathbb{P} \left( |\hat{p}_j(x) - p_j(x)| \geq \sqrt{\frac{2\sigma_j^2 u}{n}} + \frac{c_j u}{n} \right) \leq 2e^{-u}.
\]

Now, we can write

\[
\hat{\sigma}^2_j = \frac{1}{n(n-1)} \sum_{i=2}^{n} \sum_{v=1}^{i-1} \left( U_j(Y_i, W_i) - U_j(Y_v, W_v) \right)^2 \]
\[ = \frac{1}{n(n-1)} \sum_{l=2}^{n} \sum_{v=1}^{l-1} \left( U_j(Y_l, W_l) - \mathbb{E}[U_j(Y_l, W_l)] \right)^2 \]

\[ - \left( U_j(Y_v, W_v) + \mathbb{E}[U_j(Y_v, W_v)] \right)^2 \]

\[ = s_j^2 - \frac{2}{n(n-1)} \xi_j, \]

with

\[ s_j^2 := \frac{1}{n(n-1)} \sum_{l=2}^{n} \sum_{v=1}^{l-1} (U_j(Y_l, W_l) - \mathbb{E}[U_j(Y_l, W_l)])^2 \]

\[ + (U_j(Y_v, W_v) - \mathbb{E}[U_j(Y_v, W_v)])^2 \]

\[ = \frac{1}{n} \sum_{l=1}^{n} (U_j(Y_l, W_l) - \mathbb{E}[U_j(Y_l, W_l)])^2 \]

and

\[ \xi_j := \sum_{l=2}^{n} \sum_{v=1}^{l-1} (U_j(Y_l, W_l) - \mathbb{E}[U_j(Y_l, W_l)]) \times (U_j(Y_v, W_v) - \mathbb{E}[U_j(Y_v, W_v)]). \]

In the sequel, we denote for any \( \tilde{\gamma} > 0 \),

\[ \Omega_n(\tilde{\gamma}) = \left\{ \max_{1 \leq l \leq n} |\varepsilon_l| \leq s\sqrt{2\tilde{\gamma} \log n} \right\}. \]

We have that

\[ \mathbb{P}(\Omega_n(\tilde{\gamma})) \leq n^{1-\tilde{\gamma}}. \quad (25) \]

Note that on \( \Omega_n(\tilde{\gamma}) \),

\[ ||U_j(\cdot, \cdot)||_\infty \leq C_j, \]

we recall that

\[ C_j = (m + s\sqrt{2\tilde{\gamma} \log n})\|T_j\|_\infty. \]

**Lemma 1.** For any \( \tilde{\gamma} > 1 \) and any \( u > 0 \), there exists a sequence \( e_{n,j} > 0 \) such that \( \limsup_j e_{n,j} = 0 \) and

\[ \mathbb{P} \left( \sigma_j^2 \geq \frac{s_j^2}{n} + 2C_j\sigma_j \sqrt{\frac{2u(1+e_{n,j})}{n}} + \frac{\sigma_j^2 u}{3n} \bigg| \Omega_n(\tilde{\gamma}) \right) \leq e^{-u}. \]

**Proof.** We denote

\[ \mathbb{P}_{\Omega_n(\tilde{\gamma})}(\cdot) = \mathbb{P}(\cdot|\Omega_n(\tilde{\gamma})), \quad \mathbb{E}_{\Omega_n(\tilde{\gamma})}(\cdot) = \mathbb{E}(\cdot|\Omega_n(\tilde{\gamma})). \]

Note that conditionally to \( \Omega_n(\tilde{\gamma}) \) the variables \( U_j(Y_1, W_1), \ldots, U_j(Y_n, W_n) \) are independent. So, we can apply the classical Bernstein inequality to the variables

\[ V_l := \frac{\sigma_j^2}{n} - \left( U_j(Y_l, W_l) - \mathbb{E}[U_j(Y_l, W_l)] \right)^2 \leq \frac{\sigma_j^2}{n}. \]
Furthermore, as
\[
E_{\Omega_n(\gamma)}[U_j(Y_1, W_1)] = E[m(X_1)T_j(W_1)|\Omega_n(\gamma)] + E[\varepsilon_1 T_j(W_1)|\Omega_n(\gamma)]
\]
\[
= E[m(X_1)T_j(W_1)]
\]
\[
= E[U_j(Y_1, W_1)]
\]
we get
\[
\sum_{l=1}^{n} E_{\Omega_n(\gamma)}[V_l^2] = \frac{E_{\Omega_n(\gamma)} \left[ \left( \sigma_j^2 - (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^2 \right) \right]}{n}
\]
\[
= \frac{\sigma_j^4 + E_{\Omega_n(\gamma)} \left[ (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^4 \right]}{n}
\]
\[
- \frac{2\sigma_j^2 E_{\Omega_n(\gamma)} \left[ (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^2 \right]}{n}
\]
\[
\leq \frac{\sigma_j^4 + (4C_j^2 - 2\sigma_j^2) E_{\Omega_n(\gamma)} \left[ (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^2 \right]}{n}.
\]
We shall find an upper bound for \( E_{\Omega_n(\gamma)} \left[ (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^2 \right] \):
\[
E_{\Omega_n(\gamma)} \left[ (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^2 \right]
\]
\[
= \text{Var}(m(X_1)T_j(W_1)) + E[\varepsilon_1^2 T_j^2(W_1)|\Omega_n(\gamma)]
\]
\[
= \text{Var}(m(X_1)T_j(W_1)) + E[T_j^2(W_1)] \frac{E[\varepsilon_1^2 1_{\Omega_n(\gamma)}]}{P(\Omega_n(\gamma))}
\]
\[
\leq \text{Var}(m(X_1)T_j(W_1)) + E[T_j^2(W_1)] \frac{s^2}{P(\Omega_n(\gamma))}
\]
\[
\leq \text{Var}(m(X_1)T_j(W_1)) + E[T_j^2(W_1)] s^2 (1 + \tilde{e}_n)
\]
where \( \tilde{e}_n = n^{1-\gamma} + o(n^{1-\gamma}) \). Using (23) we have
\[
E_{\Omega_n(\gamma)} \left[ (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^2 \right] \leq (1 + \epsilon_{n,j}) \sigma_j^2,
\]
where \((\epsilon_{n,j})\) is a sequence such that \( \limsup_{j} \epsilon_{n,j} = 0 \). Now let us find a lower bound for \( E_{\Omega_n(\gamma)} \left[ (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^2 \right] \):
\[
E_{\Omega_n(\gamma)} \left[ (U_j(Y_1, W_1) - E[U_j(Y_1, W_1)])^2 \right]
\]
\[
= \text{Var}(m(X_1)T_j(W_1)) + E[T_j^2(W_1)] \frac{E[\varepsilon_1^2 1_{\Omega_n(\gamma)}]}{P(\Omega_n(\gamma))}
\]
\[
\geq \text{Var}(m(X_1)T_j(W_1)) + E[T_j^2(W_1)] E[\varepsilon_1^2 1_{\Omega_n(\gamma)}]
\]
Now using Cauchy-Schwarz, (20) and (25) we have
\[ E_{\Omega_\gamma}(\{(U_j(Y_1, W_1) - E[U_j(Y_1, W_1)]\}^2) \geq \sigma_j^2 - E[T_j^2(W_1)]E[\epsilon_1^2(1 - \mathbb{1}_{\Omega_\gamma}(\gamma))] \]
\[ = \sigma_j^2 - E[T_j^2(W_1)]E[\epsilon_1^2(1 - \mathbb{1}_{\Omega_\gamma}(\gamma))]. \]

Now using Cauchy-Schwarz, (20) and (25) we have
\[ E_{\Omega_\gamma}(\{(U_j(Y_1, W_1) - E[U_j(Y_1, W_1)]\}^2) \geq \sigma_j^2 - C s^2 E[T_j^2(W_1)]n^{\frac{1-\gamma}{2}} \]
\[ = \sigma_j^2(1 + \tilde{e}_{n,j}), \quad (28) \]

where \( (\tilde{e}_{n,j}) \) is a sequence such that \( \limsup_j \tilde{e}_{n,j} = 0. \)

Finally, using the bounds we just got for \( E_{\Omega_\gamma}(\{(U_j(Y_1, W_1) - E[U_j(Y_1, W_1)]\}^2) \)
yields
\[ \sum_{l=1}^n E_{\Omega_\gamma}[V_l^2] \leq \frac{\sigma_j^4 + 4C_j^2 \sigma_j^2(1 + e_{n,j}) - 2\sigma_j^4(1 + \tilde{e}_{n,j})}{n} \]
\[ \leq \frac{4C_j^2 \sigma_j^2(1 + e_{n,j}) - \sigma_j^4(1 + 2\tilde{e}_{n,j})}{n} \]
\[ \leq \frac{4C_j^2 \sigma_j^2(1 + e_{n,j})}{n}. \]

We obtain the claimed result. \( \Box \)

Now, we deal with \( \xi_j. \)

**Lemma 2.** There exists an absolute constant \( c > 0 \) such that for any \( u > 1, \)
\[ \mathbb{P}(\xi_j \geq c(n\sigma_j^2 u + C_j^2 u^2) \mid \Omega_\gamma) \leq 3e^{-u}. \]

**Proof.** Note that conditionally to \( \Omega_\gamma, \) the vectors \( (Y_t, W_t)_{1 \leq t \leq n} \) are independent. We remind that by (26), (27) and (28) we have
\[ E_{\Omega_\gamma}(U_j(Y_1, W_1)) = E[U_j(Y_1, W_1)] \quad (29) \]
and
\[ E_{\Omega_\gamma}(\{(U_j(Y_1, W_1) - E[U_j(Y_1, W_1)]\}^2) = (1 + e_{n,j})\sigma_j^2. \]

The \( \xi_j \) can be written as
\[ \xi_j = \sum_{l=2}^n \sum_{v=1}^{l-1} g_j(Y_l, W_l, Y_v, W_v), \]
with
\[ g_j(y, w, y', w') = (U_j(y, w) - E[U_j(Y_1, W_1)]) \times (U_j(y', w') - E[U_j(Y_1, W_1)]). \]

Previous computations show that conditions (2.3) and (2.4) of Houdré and Reynaud-Bouret [16] are satisfied. So that we are able to apply Theorem 3.1 of [16]: there exist absolute constants \( c_1, c_2, c_3 \) and \( c_4 \) such that for any \( u > 0, \)
\[ \mathbb{P}_{\Omega_\gamma}(\xi_j \geq c_1 C \sqrt{u} + c_2 Du + c_3 Bu^{3/2} + c_4 Au^2) \leq 3e^{-u}, \]
where $A$, $B$, $C$, and $D$ are defined and controlled as follows. We have:

$A = \|g_j\|_\infty \leq 4C_j^2$.

$$C^2 = \sum_{l=2}^{n} \sum_{v=1}^{l-1} \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})}[g_j^2(Y_l, W_l, Y_v, W_v)] = \frac{n(n-1)}{2} \sigma_j^4(1 + e_{n,j})^2.$$

Let

$$A = \left\{ (a_l), (b_v) : \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})} \left[ \sum_{l=2}^{n} \sum_{v=1}^{l-1} a_l^2(Y_l, W_l) b_v(Y_v, W_v) \right] \leq 1, \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})} \left[ \sum_{l=1}^{n-1} b_l^2(Y_l, W_l) \right] \leq 1 \right\}.$$

We have:

$$D = \sup_{(a_l), (b_v) \in A} \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})} \left[ \sum_{l=2}^{n} \sum_{v=1}^{l-1} g_l(Y_l, W_l, Y_v, W_v) a_l(Y_l, W_l) b_v(Y_v, W_v) \right]$$

$$= \sup_{(a_l), (b_v) \in A} \left[ \sum_{l=2}^{n} \sum_{v=1}^{l-1} \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})} \left[ (U_j(Y_l, W_l) - [U_j(Y_l, W_l)])a_l(Y_l, W_l) \right] \times \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})} \left[ (U_j(Y_v, W_v) - \mathbb{E}[U_j(Y_v, W_v)])b_v(Y_v, W_v) \right] \right]$$

$$\leq \sup_{(a_l), (b_v) \in A} \sum_{l=2}^{n} \sum_{v=1}^{l-1} \sigma_j^2(1 + e_{n,j}) \sqrt{\mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})}[a_l^2(Y_l, W_l)] \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})}[b_v^2(Y_v, W_v)]}$$

$$\leq \sigma_j^2(1 + e_{n,j}) \sup_{(a_l), (b_v) \in A} \sum_{l=2}^{n} \sqrt{l-1}$$

$$\times \sqrt{\sum_{l=2}^{n} \sum_{v=1}^{l-1} \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})}[a_l^2(Y_l, W_l)] \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})}[b_v^2(Y_v, W_v)]}$$

$$\leq \sigma_j^2(1 + e_{n,j}) \sqrt{\frac{n(n-1)}{2}}.$$

Finally,

$$B^2 = \sup_{y, w} \sum_{v=1}^{n-1} \mathbb{E}_{\tilde{\Omega}_n(\tilde{\gamma})} [ (U_j(y, w) - \mathbb{E}[U_j(Y_1, W_1)])^2$$

$$\times (U_j(Y_v, W_v) - \mathbb{E}[U_j(Y_1, W_1)])^2 ]$$

$$\leq 4(n-1)C_j^2 \sigma_j^2(1 + e_{n,j}).$$

Therefore, there exists an absolute constant $c > 0$ such that for any $u > 1$,

$$c_1 C\sqrt{u} + c_2 Du + c_3 Bu^{3/2} + c_4 Au^2 \leq c(n \sigma_j^2 + C_j^2 u^2).$$
Let us go back to the proof of Proposition 1. We apply Lemmas 1 and 2 with $u > 1$ and we obtain, by setting

$$M_j(u) = \hat{\sigma}_j^2 + 2C_j\sigma_j \sqrt{\frac{2u(1 + e_{n,j})}{n}} + \frac{\sigma_j^2 u^2}{3n} + \frac{2c(n\sigma_j^2 u + C_j^2 u^2)}{n(n-1)},$$

$$P(\sigma_j^2 \geq M_j(u)) \leq P\left(\sigma_j^2 \geq s_j^2 - \frac{2}{n(n-1)}\xi_j + 2C_j\sigma_j \sqrt{\frac{2u(1 + e_{n,j})}{n}} \right.$$

$$\left. + \frac{\sigma_j^2 u^2}{3n} + \frac{2c(n\sigma_j^2 u + C_j^2 u^2)}{n(n-1)}\right)$$

$$\leq P\left(\sigma_j^2 \geq s_j^2 + 2C_j\sigma_j \sqrt{\frac{2u(1 + e_{n,j})}{n}} + \frac{\sigma_j^2 u^2}{3n} \Omega_n(\tilde{\gamma}) \right.$$

$$\left. + P(\xi_j \geq c(n\sigma_j^2 u + C_j^2 u^2)|\Omega_n(\tilde{\gamma})) + 1 - P(\Omega_n(\tilde{\gamma}))\right).$$

Therefore, with $u = \tilde{\gamma}\log n$ and $\tilde{\gamma} > 1$, we obtain for $n$ large enough:

$$P(\sigma_j^2 \geq M_j(\tilde{\gamma}\log n)) \leq 5n^{-5}.$$

And there exist $a$ and $b$ two absolute constants such that

$$P\left(\sigma_j^2 \geq \hat{\sigma}_j^2 + 2C_j\sigma_j \sqrt{\frac{2\tilde{\gamma}\log n(1 + e_{n,j})}{n}} + \frac{\sigma_j^2 a\tilde{\gamma}\log n}{n} + \frac{C_j^2 b^2\tilde{\gamma}^2 \log^2 n}{n^2}\right) \leq 5n^{-5}.$$

Now, we set

$$\theta_1 = \left(1 - \frac{a\tilde{\gamma}\log n}{n}\right), \ \theta_2 = C_j\sqrt{\frac{2\tilde{\gamma}\log n(1 + e_{n,j})}{n}}, \ \theta_3 = \hat{\sigma}_j^2 + \frac{C_j^2 b^2\tilde{\gamma}^2 \log^2 n}{n^2},$$

so

$$P(\theta_1\sigma_j^2 - 2\theta_2\sigma_j - \theta_3 \geq 0) \leq 5n^{-5}.$$

We study the polynomial

$$p(\sigma) = \theta_1\sigma^2 - 2\theta_2\sigma - \theta_3.$$

Since $\sigma \geq 0$, $p(\sigma) \geq 0$ means that

$$\sigma \geq \frac{1}{\theta_1} \left(\theta_2 + \sqrt{\theta_2^2 + \theta_1\theta_3}\right),$$

which is equivalent to

$$\sigma^2 \geq \frac{1}{\theta_1^2} \left(2\theta_2^2 + \theta_1\theta_3 + 2\theta_2\sqrt{\theta_2^2 + \theta_1\theta_3}\right).$$

Hence

$$P(\sigma_j^2 \geq \frac{1}{\theta_1^2} \left(2\theta_2^2 + \theta_1\theta_3 + 2\theta_2\sqrt{\theta_2^2 + \theta_1\theta_3}\right)) \leq 5n^{-5}.$$
Adaptive wavelet multivariate regression with errors in variables

So,
\[ P \left( \sigma_j^2 \geq \frac{\theta_3}{\theta_1} + \frac{2\theta_2}{\theta_1} \sqrt{\sigma_j^2} + \frac{4\theta_2^2}{\theta_1^2} \right) \leq 5n^{-\gamma}. \]

So, there exist absolute constants \( \delta, \eta, \) and \( \tau' \) depending only on \( \tilde{\gamma} \) so that for \( n \) large enough,
\[ P \left( \sigma_j^2 \geq \tilde{\sigma}_j^2 \left( 1 + \delta \log \frac{n}{n} \right) \right) \leq 5n^{-\gamma}. \]

Finally, for all \( \tilde{\varepsilon} > 0 \) there exists \( R_4 \) depending on \( \varepsilon' \) and \( \tilde{\gamma} \) such that for \( n \) large enough
\[ P(\sigma_j^2 \geq (1 + \varepsilon')\tilde{\sigma}_j^2, \tilde{\gamma}) \leq R_4 n^{-\gamma}. \]

Combining this inequality with (24), we obtain the desired result of Proposition 1.

Proposition 2 shows that the residual term in the oracle inequality is negligible.

**Proposition 2.** We have for any \( q \geq 1, \)
\[ E \left[ \sup_{j \in J} \left( |\tilde{p}_j(x) - p_j(x)| - \Gamma_\gamma(j) \right)^q \right] \leq R_1' n^{-q}, \]
with \( R_1' \) a constant depending on \( s, m, d, \phi, c_g, C_g \) and \( \varphi. \)

**Proof.** We recall that \( J = \left\{ j \in \mathbb{N}^d : 2^{S_j} \leq \left\lfloor \frac{n}{\log^2 n} \right\rfloor \right\}. \)

Let \( \tilde{\gamma} > 0 \) and let us consider the event
\[ \tilde{\Omega}_{\tilde{\gamma}} = \{ \sigma_j^2 \leq (1 + \varepsilon)\tilde{\sigma}_j^2, \forall j \in J \}. \]

Let \( \gamma > 0. \) We set in the sequel
\[ E := E \left[ \sup_{j \in J} \left( |\tilde{p}_j(x) - p_j(x)| - \sqrt{\frac{2\gamma(1 + \varepsilon)\tilde{\sigma}_j^2 \log n}{n} - c_j \gamma \log n} \right)^q \right] \sigma_j^2 \}
\]
and \( R_j := |\tilde{p}_j(x) - p_j(x)|. \) We have:
\[ E = \int_0^\infty P \left[ \sup_{j \in J} \left( R_j - \sqrt{\frac{2\gamma(1 + \varepsilon)\tilde{\sigma}_j^2 \log n}{n} - c_j \gamma \log n} \right)^q \right] I_{\tilde{\Omega}_{\tilde{\gamma}}} > y \right] dy \]
\[ \leq \sum_{j \in J} \int_0^\infty P \left[ \left( R_j - \sqrt{\frac{2\gamma(1 + \varepsilon)\tilde{\sigma}_j^2 \log n}{n} - c_j \gamma \log n} \right)^q \right] I_{\tilde{\Omega}_{\tilde{\gamma}}} > y \right] dy \]
\[
\sum_{j \in J} \int_0^\infty \mathbb{P} \left[ R_j > \sqrt{\frac{2\gamma \sigma_j^2 \log n}{n} - \frac{c_j \gamma \log n}{n}} \right] dy.
\]

Let us take \(u\) such that
\[
y = h(u)^q,
\]
where
\[
h(u) = \sqrt{\frac{2\sigma_j^2 u}{n}} + \frac{c_j u}{n}.
\]

Note that for any \(u > 0\),
\[
h'(u) \leq \frac{h(u)}{u}.
\]

Hence
\[
E \leq C \sum_{j \in J} \int_0^\infty \mathbb{P} \left[ R_j > \sqrt{\frac{2\gamma \sigma_j^2 \log n}{n} + \frac{c_j \gamma \log n}{n} + \frac{2u \sigma_j^2}{n} + \frac{uc_j}{n}} \right] h(u)^{q-1} h'(u) du
\]
\[
\leq C \sum_{j \in J} \int_0^\infty \mathbb{P} \left[ R_j > \sqrt{\frac{2\sigma_j^2 (\gamma \log n + u)}{n} + \frac{c_j (\gamma \log n + u)}{n}} \right] h(u)^{q-1} h'(u) du.
\]

Now using concentration inequality (18), we get
\[
E \leq C \sum_{j \in J} \int_0^\infty e^{-(\gamma \log n + u) h(u)^q h'(u) du}
\]
\[
\leq C \sum_{j \in J} \int_0^\infty e^{-(\gamma \log n + u) h(u)^q \frac{1}{u}} du
\]
\[
\leq C e^{-\gamma \log n} \sum_{j \in J} \int_0^\infty e^{-u} \left( \frac{2\sigma_j^2}{n} + \frac{c_j u}{n} \right)^{q} \frac{1}{u} du
\]
\[
\leq C \left( e^{-\gamma \log n} \sum_{j \in J} \left( \frac{\sigma_j^2}{n} \right)^{q/2} \int_0^\infty e^{-u} u^{2-1} du + \left( \frac{c_j}{n} \right)^{q} \int_0^\infty e^{-u} u^{q-1} du \right).
\]

Now using Lemma 10, we have that \(\sigma_j^2 \leq R_{10} 2^{(2\nu + S_j)}\) and \(c_j \leq C 2^{S_j \nu + S_j}\). Hence,
\[
E \leq C \left( e^{-\gamma \log n} \sum_{j \in J} \left( \frac{2^{(2\nu + S_j)}}{n} \right)^{q/2} + \left( \frac{2^{(S_j \nu + S_j)}}{n} \right)^{q} \right)
\]
\[
\leq C n^{-\gamma + q \nu} (\log n)^{-(2\nu + 1)q} \leq C n^{-q},
\]
as soon as \(\gamma > q(\nu + 1)\).
It remains to find an upperbound for the following quantity:

\[ E' := E \left[ \sup_{j \in J} \left( \left| \hat{p}_j(x) - p_j(x) \right| \right) \right. \left. - \sqrt{\frac{2\gamma(1 + \varepsilon) \sigma_j^2 \log n}{n}} - c_j \gamma \log n \right] + \mathbb{I}_{\tilde{\Omega}_0}^q . \]

We have

\[ E' \leq E \left[ \sup_{j \in J} (|\hat{p}_j(x) - p_j(x)|^q \mathbb{I}_{\tilde{\Omega}_0}) \right] \]

\[ \leq 2^{q-1} \left( E \left[ \sup_{j \in J} (|\hat{p}_j(x)|^q \mathbb{I}_{\tilde{\Omega}_0}) \right] + E \left[ \sup_{j \in J} (|p_j(x)|^q \mathbb{I}_{\tilde{\Omega}_0}) \right] \right) . \]

First, let us deal with the term \( E \left[ \sup_{j \in J} (|p_j(x)|^q \mathbb{I}_{\tilde{\Omega}_0}) \right] \).

Following the lines of the proof of Lemma 7 we easily get that \( \sum_k \varphi_j^2(x) \leq C n^S \), hence

\[ |p_j(x)| = \left| \sum_k p_{jk} \varphi_{jk}(x) \right| \leq \left( \sum_k p_{jk}^2 \right)^{\frac{1}{2}} \left( \sum_k \varphi_{jk}^2(x) \right)^{\frac{1}{2}} \]

\[ \leq C \|p\|_2^{\frac{S}{2}} . \]

Now using Proposition 1 which states that \( P(\tilde{\Omega}_0^c) \leq C n^{-\gamma} \)

\[ E \left[ \sup_{j \in J} (|p_j(x)|^q \mathbb{I}_{\tilde{\Omega}_0}) \right] \leq \sup_{j \in J} (\|p\|_2^{\frac{S}{2}})^q P(\tilde{\Omega}_0^c) \]

\[ \leq C \left( \frac{n}{\log^2 n} \right)^{\frac{1}{2}} n^{-\gamma} . \]

It remains to find an upperbound for \( E \left[ \sup_{j \in J} (|\hat{p}_j(x)|^q \mathbb{I}_{\tilde{\Omega}_0}) \right] \). We have

\[ E \left[ \sup_{j \in J} (|\hat{p}_j(x)|^q \mathbb{I}_{\tilde{\Omega}_0}) \right] \]

\[ = E \left[ \sup_{j \in J} \left\{ \frac{1}{n} \sum_{l=1}^n Y_l T_j(W_l) \right\}^q \mathbb{I}_{\tilde{\Omega}_0} \right] \]

\[ \leq \frac{1}{n^q} E \left[ \sup_{j \in J} \left( \sum_{i=1}^n |m(X_i) + \varepsilon_l| |T_j(W_l)| \right)^q \mathbb{I}_{\tilde{\Omega}_0} \right] \]

\[ \leq \frac{n^{q-1}}{n^q} E \left[ \sup_{j \in J} \sum_{i=1}^n |m(X_i) + \varepsilon_l|^q |T_j(W_l)|^q \mathbb{I}_{\tilde{\Omega}_0} \right] \]

\[ \leq \frac{C}{n} E \left[ \sup_{j \in J} \sum_{i=1}^n (|m|_\infty^q + |\varepsilon_l|^q) |T_j(W_l)|^q \mathbb{I}_{\tilde{\Omega}_0} \right] . \]
\[
\begin{align*}
\leq C \left( \sup_{j \in J} (\|T_j\|_\infty \mathbb{P}(\Omega_j^c)) + \sup_{j \in J} (\|T_j\|_\infty q) \mathbb{E} \left[ |\varepsilon_1|^q 1_{\tilde{\Omega}_j^c} \right] \right) \\
\leq C \left( \sup_{j \in J} (\|T_j\|_\infty \mathbb{P}(\Omega_j^c)) + s^q \sup_{j \in J} (\|T_j\|_\infty q) \left( \mathbb{E} \left[ |\varepsilon|^q \right] \right)^{\frac{q}{2}} \left( \mathbb{P}(\tilde{\Omega}_j^c) \right)^{\frac{1}{2}} \right),
\end{align*}
\]
where \( Z \sim \mathcal{N}(0, 1) \). Using (20) and \( \|T_j\|_\infty \leq T_4 S_j (\nu + 1) \), we get
\[
\mathbb{E} \left[ \sup_{j \in J} (|\hat{p}_j(x)| q 1_{\tilde{\Omega}_j^c}) \right] \leq C \left( \frac{n}{\log^2 n} \right)^{(\nu + 1)_q} n^{-\frac{q}{2}},
\]
We have
\[
E' \leq C n^{-\frac{q}{2}} \left( \frac{n}{\log^2 n} \right)^{\frac{q}{2}} + \left( \frac{n}{\log^2 n} \right)^{(\nu + 1)_q}
\]
\[
\leq C n^{-q},
\]
as soon as \( \tilde{\gamma} > 2q(\nu + 2) \). This ends the proof of Proposition 2.

Proposition 3 controls the bias term in the oracle inequality.

**Proposition 3.** For any \( j = (j_1, \ldots, j_d) \in \mathbb{Z}^d \) and \( j' = (j'_1, \ldots, j'_d) \in \mathbb{Z}^d \) and any \( x \), if \( p \in \mathbb{H}_d(\tilde{\beta}, L) \)
\[
|p_{j \wedge j'}(x) - p_{j'}(x)| \leq R_{12} L \sum_{l=1}^d 2^{-j_l \beta_l},
\]
where \( R_{12} \) is a constant only depending on \( \varphi \) and \( \tilde{\beta} \). We have denoted
\[
j \wedge j' = (j_1 \wedge j'_1, \ldots, j_d \wedge j'_d).
\]

**Proof.** We first state three lemmas.

**Lemma 3.** For any \( j \) and any \( k \), we have:
\[
\mathbb{E}[\hat{p}_{jk}] = p_{jk}.
\]

**Proof.** Recall that
\[
\hat{p}_{jk} := \frac{1}{n} \sum_{u=1}^n Y_u \times (D_j \varphi)_{j,k}(W_u) = \frac{2^s}{(2\pi)^d} 1_{n \sum_{u=1}^n Y_u} \int e^{-i t \cdot 2^j W_u - k} \frac{f(\varphi)(t)}{f(g)(2^j t)} dt.
\]
Let us prove now that \( \mathbb{E}(\hat{p}_{jk}) = p_{jk} \).
We have
\[
\mathbb{E}(\hat{p}_{jk}) = \frac{2^s}{(2\pi)^d} \left( \int \mathbb{E}(Y_1 e^{-i t \cdot 2^j W_1 - k}) \frac{f(\varphi)(t)}{f(g)(2^j t)} dt \right).
\]
We shall develop the right member of the last equality. We have:

\[
E \left[ Y_1 e^{-i < t, 2^j W_1 - k >} \right] = E \left[ (m(X_1) + \varepsilon_1) e^{-i < t, 2^j W_1 - k >} \right] = E \left[ m(X_1) e^{-i < t, 2^j X_1 - k >} \right] + E \left[ \varepsilon_1 e^{-i < t, 2^j \delta_1 >} \right] = \int m(x) e^{-i < t, 2^j x - k >} f_x(x) dx \times F(g)(2^j t) = e^{i < t, k >} F(p)(2^j t) F(g)(2^j t).
\]

Consequently

\[
E [\hat{p}_{jk}] = \frac{2^{s_j}}{(2\pi)^d} \int e^{i < t, k >} F(p)(2^j t) F(g)(2^j t) \frac{d}{dt} \left[ F(\varphi)(t) \right] dt = \frac{2^{s_j}}{(2\pi)^d} \int e^{i < t, k >} F(p)(2^j t) F(\varphi)(t) dt = \frac{1}{(2\pi)^d} \int F(p)(t) F(\varphi_{jk})(t) dt.
\]

Since by Parseval equality, we have

\[
p_{jk} = \int p(t) \varphi_{jk}(t) dt = \frac{1}{(2\pi)^d} \int F(p)(t) F(\varphi_{jk})(t) dt,
\]

the result follows.

Note that in the case where we don’t have any noise on the variable i.e \( g(x) = \delta_0(x) \), since \( F(g)(t) = 1 \), the proof above remains valid and we get 
\( E[\hat{p}_{jk}] = p_{jk} \).

**Lemma 4.** If for any \( l, |\beta_l| \leq N \), the following holds: for any \( j \in \mathbb{Z}^d \) and any \( p \in \mathbb{H}_d(\beta, L) \),

\[
|E[\hat{p}_j(x)] - p(x)| \leq L(\|\varphi\|_{\infty} \|\varphi\|_1)(2A + 1)^d \sum_{l=1}^{d} \frac{(2A \times 2^{-j_l})^{\beta_l}}{[\beta_l]!}.
\]

**Proof.** Let \( x \) be fixed and \( j = (j_1, \ldots, j_d) \in \mathbb{Z}^d \). We have:

\[
\int K_j(x, y) dy = \sum_{k_1} \cdots \sum_{k_d} \prod_{l=1}^{d} \left[ 2^{j_l} \varphi(2^{j_l} x_l - k_l) \varphi(2^{j_l} y_l - k_l) \right] = 1.
\]

Therefore, using lemma 3

\[
E[\hat{p}_j(x)] - p(x) = p_j(x) - p(x)
\]
\[ = \int K_j(x, y)(p(y) - p(x)) dy \]
\[ = \sum_k \varphi_{jk}(x) \int \varphi_{jk}(y)(p(y) - p(x)) dy \]
\[ = \sum_{k_1 \in Z_{j,1}(x)} \cdots \sum_{k_d \in Z_{j,d}(x)} \varphi_{jk}(x) \int \prod_{l=1}^d 2^{\frac{j_l}{2}} \varphi(2^{j_l} y_l - k_l)(p(y) - p(x)) dy. \]

Now, we use that
\[ p(y) - p(x) = \sum_{l=1}^d p(x_1, \ldots, x_{l-1}, y_l, y_{l+1}, \ldots, y_d) - p(x_1, \ldots, x_{l-1}, x_l, y_{l+1}, \ldots, y_d), \]
with \( p(x_1, \ldots, x_l, y_{l+1}, \ldots, y_d) = p(x_1, \ldots, x_d) \) if \( l = d \) and \( p(x_1, \ldots, x_{l-1}, y_l, \ldots, y_d) = p(y_1, \ldots, y_d) \) if \( l = 1 \). Furthermore, the Taylor expansion gives: for any \( l \in \{1, \ldots, d\} \), for some \( u_l \in [0; 1] \),
\[ p(x_1, \ldots, x_{l-1}, y_l, y_{l+1}, \ldots, y_d) - p(x_1, \ldots, x_{l-1}, x_l, y_{l+1}, \ldots, y_d) = \]
\[ = \sum_{|\beta| = 1} \frac{\partial^{|\beta|} p}{\partial x^{|\beta|}} (x_1, \ldots, x_{l-1}, x_l, y_{l+1}, \ldots, y_d) \times (y_l - x_l)^{|\beta|}/|\beta|! + \]
\[ \frac{\partial^{|\beta|} p}{\partial x^{|\beta|}} (x_1, \ldots, x_{l-1}, x_l + (y_l - x_l) u_l, y_{l+1}, \ldots, y_d) \times (y_l - x_l)^{|\beta|}/|\beta|! \]
\[ - \frac{\partial^{|\beta|} p}{\partial x^{|\beta|}} (x_1, \ldots, x_{l-1}, x_l, y_{l+1}, \ldots, y_d) \times (y_l - x_l)^{|\beta|}/|\beta|!. \]

Using vanishing moments of \( K_j \) and \( p \in \mathbb{H}_d(\overline{\beta}, L) \), we obtain:
\[ |p_j(x) - p(x)| \]
\[ \leq \sum_{k_1 \in Z_{j,1}(x)} \cdots \sum_{k_d \in Z_{j,d}(x)} |\varphi_{jk}(x)| \int \prod_{l=1}^d 2^{\frac{j_l}{2}} |\varphi(2^{j_l} y_l - k_l)| \sum_{l=1}^d L |y_l - x_l|^{|\beta_l|}/|\beta_l|! dy \]
\[ \leq \|\varphi\|_\infty^d \sum_{k_1 \in Z_{j,1}(x)} \cdots \sum_{k_d \in Z_{j,d}(x)} \int_{[-A; A]^d} \prod_{l=1}^d |\varphi(u_l)| \sum_{l=1}^d L (2^{-j_l}(u_l + k_l) - x_l)^{|\beta_l|}/|\beta_l|! du. \]

Since for any \( l, k_l \in Z_{j,l}(x) \), we finally obtain
\[ |p_j(x) - p(x)| \]
\[ \leq \|\varphi\|_\infty^d \sum_{k_1 \in Z_{j,1}(x)} \cdots \sum_{k_d \in Z_{j,d}(x)} \int_{[-A; A]^d} \prod_{l=1}^d |\varphi(u_l)| \sum_{l=1}^d L (2A \times 2^{-j_l})^{|\beta_l|}/|\beta_l|! du \]
\[ \leq L(\|\varphi\|_\infty \|\varphi\|_1)^d (2A + 1)^d \sum_{l=1}^d \frac{(2A \times 2^{-j_l})^{|\beta_l|}}{|\beta_l|!}. \]
Lemma 5. We have for any \( j = (j_1, \ldots, j_d) \in \mathbb{Z}^d \) and \( j' = (j'_1, \ldots, j'_d) \in \mathbb{Z}^d \) and any \( x \),

\[
K_{j'}(p_j)(x) = p_{j \wedge j'}(x).
\]

Proof. We only deal with the case \( d = 2 \). The extension to the general case can be easily deduced. If for \( i = 1, 2 \), \( j_i \leq j_i' \) the result is obvious. It is also the case if for \( l = 1, 2 \), \( j_i' \leq j_i \). So, without loss of generality, we assume that \( j_1 \leq j'_1 \) and \( j_2' \leq j_2 \). We have:

\[
K_{j'}(p_j)(x) = \int K_{j'}(x, y)p_j(y)dy
= \int \sum_k \varphi_{j'_k}(x)\varphi_{j'_k}(y)p_j(y)dy
= \int \sum \sum_{k_1} \varphi_{j'_1 k_1}(x_1)\varphi_{j'_2 k_2}(x_2)\varphi_{j_1 k_1}(y_1)\varphi_{j_2 k_2}(y_2)p_j(y)dy_1dy_2
= \int \sum \sum_{k_1} \varphi_{j'_1 k_1}(x_1)\varphi_{j'_2 k_2}(x_2)\varphi_{j_1 k_1}(y_1)\varphi_{j_2 k_2}(y_2)
\times \sum \sum_{\ell_1} \varphi_{j_1 \ell_1}(y_1)\varphi_{j_2 \ell_2}(y_2)\varphi_{j_1 \ell_1}(u_1)\varphi_{j_2 \ell_2}(u_2)p(u_1, u_2)du_1du_2dy_1dy_2.
\]

Since \( j_1 \leq j'_1 \), we have in the one-dimensional case, by a slight abuse of notation, \( V_{j_1} \subset V_{j'_1} \) and

\[
\int \sum_{k_1} \varphi_{j'_1 k_1}(x_1)\varphi_{j'_1 k_1}(y_1)\varphi_{j_1 \ell_1}(y_1)dy_1 = \int K_{j'_1}(x_1, y_1)\varphi_{j_1 \ell_1}(y_1)dy_1 = \varphi_{j_1 \ell_1}(x_1).
\]

Similarly, since \( j_2' \leq j_2 \), we have \( V_{j'_2} \subset V_{j_2} \) and

\[
\int \sum_{\ell_2} \varphi_{j_2 \ell_2}(y_2)\varphi_{j_2 \ell_2}(u_2)\varphi_{j_2 \ell_2}(y_2)dy_2 = \int K_{j_2}(u_2, y_2)\varphi_{j_2 \ell_2}(y_2)dy_2 = \varphi_{j_2 \ell_2}(u_2).
\]

Therefore, with \( \tilde{j} = j \wedge j' \),

\[
K_{j'}(p_j)(x) = \int \sum \sum_{k_2} \varphi_{j'_2 k_2}(x_2)\varphi_{j_1 \ell_1}(u_1)\varphi_{j_1 \ell_1}(x_1)\varphi_{j'_2 k_2}(u_2)p(u_1, u_2)du_1du_2
= \int \sum \sum_{\ell_2} \varphi_{j_2 \ell_2}(x_2)\varphi_{j_1 \ell_1}(u_1)\varphi_{j_1 \ell_1}(x_1)\varphi_{j_2 \ell_2}(u_2)p(u_1, u_2)du_1du_2
= \int \sum \varphi_{j_\ell}(x)\varphi_{j_\ell}(u)p(u)du
= p_j(x),
\]

which ends the proof of the lemma. □
Now, we shall go back to the proof of Proposition 3. We easily deduce the result:

\[ p_{j, j'}(x) - p_{j'}(x) = K_{j'}(p_j)(x) - K_{j'}(p)(x) \]

\[ = \int K_{j'}(x, y)(p_j(y) - p(y))dy. \]

Therefore,

\[ |p_{j, j'}(x) - p_{j'}(x)| \leq \int |K_{j'}(x, y)||p_j(y) - p(y)||dy \]

\[ \leq R_{12}L \sum_{l=1}^{d} 2^{-j_l \beta_l} \times \int |K_{j'}(x, y)||dy, \]

where \( R_{12} \) is a constant only depending on \( \varphi \) and \( \beta \). We conclude by observing that

\[ \int |K_{j'}(x, y)||dy = \int \sum_{k_1} \cdots \sum_{k_d} (\sum_{l=1}^{d} 2^{j_l} |\varphi(2^{j_l} x_l - k_l)||\varphi(2^{j_l} y_l - k_l)||dy_l) \]

\[ \leq \|\varphi\|_{\infty}^d \sum_{k_1 \in Z_{j', d}(x)} \cdots \sum_{k_d \in Z_{j', d}(x)} \left( \int |\varphi(v)||dv \right)^d \]

\[ \leq (\|\varphi\|_{\infty} \|\varphi\|_1 (2A + 1))^d. \]

We thus obtain the claimed result of Proposition 3.

\[ \square \]

5.2.2. Appendix

Technical lemmas are stated and proved below.

**Lemma 6.** We have

\[ \mathbb{E}[(\hat{\sigma}_{j, \tilde{\gamma}})^q] \leq R_5 2^{S_j(2\nu + 1) \tilde{\gamma}^2}, \]

with \( R_5 \) a constant depending on \( q, \tilde{\gamma}, m, s, \vartheta, \varphi, c_g, C_g \).

**Proof.** First, let us focus on the case \( q \geq 2 \). We recall the expression of \( \hat{\sigma}_{j, \tilde{\gamma}}^2 \)

\[ \hat{\sigma}_{j, \tilde{\gamma}}^2 = \hat{\sigma}_j^2 + 2C_j \sqrt{\tilde{\gamma} \hat{\sigma}_j^2 \frac{\log n}{n}} + 8\tilde{\gamma} C_j \frac{\log n}{n}. \]

We shall first prove that

\[ \mathbb{E}[(\hat{\sigma}_j)^q] \leq C 2^{S_j(2\nu + 1) \tilde{\gamma}^2}. \]

Let us remind that

\[ \hat{\sigma}_j^2 = \frac{1}{2n(n - 1)} \sum_{i \neq v} (U_j(Y_i, W_i) - U_j(Y_v, W_v))^2. \]
We easily get
\[ \hat{\sigma}_j^2 \leq \frac{C}{n} \sum_i (U_j(Y_i, W_i) - \mathbb{E}[U_j(Y_1, W_1)])^2. \]

First let us remark that
\[
\left( \sum_i (U_j(Y_i, W_i) - \mathbb{E}[U_j(Y_1, W_1)])^2 \right)^{\frac{q}{2}} \leq C \left( \left( \sum_i ((U_j(Y_i, W_i) - \mathbb{E}[U_j(Y_1, W_1)])^2 - \sigma_j^2) \right)^{\frac{q}{2}} + n^{\frac{q}{2}} \sigma_j^q \right)
\]

We will use Rosenthal inequality (see [15]) to find an upper bound for
\[
\mathbb{E} \left[ \left( \sum_i ((U_j(Y_i, W_i) - \mathbb{E}[U_j(Y_1, W_1)])^2 - \sigma_j^2) \right)^{\frac{q}{2}} \right].
\]

We set
\[ B_l := (U_j(Y_i, W_i) - \mathbb{E}[U_j(Y_1, W_1)])^2 - \sigma_j^2. \]

The variables \( B_l \) are i.i.d and centered. We have to check that \( \mathbb{E}[|B_l|^{\frac{q}{2}}] < \infty \).

We have
\[
\mathbb{E}[|B_l|^{\frac{q}{2}}] \leq C(\mathbb{E}[(U_j(Y_i, W_i) - \mathbb{E}[U_j(Y_1, W_1)])^q] + \sigma_j^q),
\]

but
\[
\mathbb{E}[(U_j(Y_i, W_i) - \mathbb{E}[U_j(Y_1, W_1)])^q] = \frac{A_q}{n},
\]

with \( A_q \) defined in (19). Hence
\[
\mathbb{E}[|B_l|^{\frac{q}{2}}] \leq C \left( \frac{A_q}{n} + \sigma_j^q \right). \quad (33)
\]

Using the control of \( A_q \) in (21), equation (22) and Lemma 10 we have
\[
A_q \leq C n \sigma_j^q \| T_j \|_2^{-2} \leq C n 2^{S_j(q^r+q-2)}. \quad (34)
\]

Now, we are able to apply the Rosenthal inequality to the variables \( B_l \) which yields
\[
\mathbb{E} \left[ \left( \sum_i B_l \right)^{\frac{q}{2}} \right] \leq C \left( \sum_i \mathbb{E}[|B_l|^{\frac{q}{2}}] + \left( \sum_i \mathbb{E}[B_l^q] \right)^{\frac{q}{2}} \right),
\]

and using (33) and (34) we get
\[
\mathbb{E} \left[ \left( \sum_i B_l \right)^{\frac{q}{2}} \right] \leq C \left( \sum_i \left( \frac{A_q}{n} + \sigma_j^q \right) + \left( \sum_i \left( \frac{A_q}{n} + \sigma_j^q \right) \right)^{\frac{q}{2}} \right).
\]
\[ \leq C \left( A_d + n\sigma_j^q + (A_d)^{\frac{q}{2}} + n^{\frac{q}{2}}\sigma_j^q \right) \]
\[ \leq C \left( n^2S_j(q^2+q-1) + n^2S_j(2\nu+1)\frac{q}{2} + (n^2S_j(4\nu+3)^{\frac{q}{2}} \right). \]

Consequently
\[ E[\sigma_j^q] \leq Cn^{-\frac{q}{2}} \left( n^2S_j(q^2+q-1) + n^2S_j(2\nu+1)\frac{q}{2} + (n^2S_j(4\nu+3)^{\frac{q}{2}} \right) \]
\[ \leq C(n^{1-\frac{q}{2}}2^S_j q^2 + n^{1-\frac{q}{2}}2^S_j(2\nu+1)\frac{q}{2} + n^{-\frac{q}{2}}2^S_j(4\nu+3)^{\frac{q}{2}} + 2^S_j(2\nu+1)\frac{q}{2}). \]

Let us compare each term of the r.h.s of the last inequality. We have
\[ n^{1-\frac{q}{2}}2^S_j q^2 \leq 2^S_j(2\nu+1)\frac{q}{2} \iff 2^S_j \leq n, \]
which is true by (12). Similarly we have
\[ n^{1-\frac{q}{2}}2^S_j(4\nu+3)^{\frac{q}{2}} \leq 2^S_j(2\nu+1)\frac{q}{2} \iff 2^S_j \leq n, \]
and obviously
\[ n^{1-\frac{q}{2}}2^S_j(2\nu+1)\frac{q}{2} \leq 2^S_j(2\nu+1)\frac{q}{2}. \]

Thus we get that the dominant term in r.h.s is \( 2^S_j(2\nu+1)\frac{q}{2} \). Hence
\[ E[\sigma_j^q] \leq C2^S_j(2\nu+1)\frac{q}{2}. \]

Now using that
\[ E[\sigma_{j,5}^q] \leq C \left( E[\sigma_j^q] + \left( 2C_j \sqrt{2^{\gamma_j} \log n} \right)^{\frac{q}{2}} E[\sigma_j^q] + \left( 8C_j^{\prime} \log n \right)^{\frac{q}{2}} \right), \]
and since \( C_j \leq C \sqrt{\log n}2^S_j(\nu+1) \), we have
\[ E[\sigma_{j,5}^q] \leq C \left( 2^S_j(2\nu+1)\frac{q}{2} + ((\log n)n^{1-\frac{q}{2}}2^S_j(\nu+1)\frac{q}{2} + 2^S_j(2\nu+1)^{\frac{q}{2}} \right. \]
\[ \left. + \left( \log n \right\frac{q}{2}2^S_j(2\nu+1)\frac{q}{2} \right)^{\frac{q}{2}}. \]

Let us compare the three terms of the right hand side. We have
\[ 2^S_j \frac{n(2\nu+1)}{2} \geq ((\log n)n^{1-\frac{q}{2}}2^S_j(\nu+1)\frac{q}{2} + 2^S_j(2\nu+1)^{\frac{q}{2}} \left. \iff 2^S_j(q^2+\frac{q}{2}) \geq \log n \frac{q}{2}n^{-\frac{q}{2}}2^S_j(\nu+1) \iff 2^S_j \leq \frac{n}{\log^2 n}, \]
which is true by (12). Furthermore we have
\[ 2^S_j \frac{n(2\nu+1)}{2} \geq \left( \frac{\log n}{2}2^S_j(\nu+1) \right)^{\frac{q}{2}}. \]
\[ \iff 2^{S_j(q^\nu + \frac{q}{2})} \geq \left( \frac{\log^2 n}{n} \right)^{\frac{q}{2}} 2^{S_j(q^\nu + q)} \iff 2^{S_j} \leq \frac{n}{\log^2 n}, \tag{35} \]

which is true again by (12). Consequently

\[ \mathbb{E}[\tilde{\sigma}_{j,\gamma}] \leq R_5 2^{S_j(2\nu + 1)} \frac{2}{q}, \]

with \( R_5 \) a constant depending on \( q, \bar{\gamma}, m, s, \varphi, c_g, C_g \) and the lemma is proved for \( q \geq 2 \).

For the case \( q \leq 2 \) the result follows from Jensen inequality. \( \square \)

**Lemma 7.** Under Assumption (A1) on the father wavelet \( \varphi \), we have for any \( j = (j_1, \ldots, j_d) \) and any \( x \in \mathbb{R}^d \),

\[ \sum_k |\varphi_{jk}(x)| \leq (2A + 1)^d \|\varphi\|_\infty 2^{\frac{S_j}{2}}. \]

**Proof.** A proof of this standard result can be found in Section 4.2 in [13]. \( \square \)

**Lemma 8.** Under condition (A1) and \( \varphi \) is \( C^r \), there exist constants \( R_6 \) and \( R_7 \) depending on \( \varphi \) such that

\[ |\mathcal{F}(\varphi)(t)| \leq R_6 (1 + |t|)^{-r}, \quad \text{for any } t \in \mathbb{R}. \tag{36} \]

and

\[ \left| \mathcal{F}(\varphi)(t) \right| \leq R_7 (1 + |t|)^{-r}, \quad \text{for any } t \in \mathbb{R}. \tag{37} \]

**Proof.** A proof of this result can be found in Section 4.2 of [13]. \( \square \)

**Lemma 9.** Under conditions (A1) and (A3), for \( \nu \geq 0 \), we have

\[ |(D_j \varphi)(w)| \leq R_8 2^{S_j \nu} \prod_{l=1}^d (1 + |w_l|)^{-1}, \quad w \in \mathbb{R}^d \]

where \( R_8 \) is a constant depending on \( \varphi, C_g \) and \( c_g \).

**Proof.** If all the \( |w_l| < 1 \) then using (3), Lemma 8 and \( r > \nu + 1 \) with \( \nu \geq 0 \) we have

\[ |(D_j \varphi)(w)| \leq \int \prod_{l=1}^d \frac{\left| \mathcal{F}(\varphi)(t_l) \right|}{\left| \mathcal{F}(g)(2^j t_l) \right|} dt \leq C \prod_{l=1}^d \int \left| \mathcal{F}(\varphi)(t_l)(1 + 2^j |t_l|)^\nu \right| dt_l \leq C 2^{S_j \nu} \prod_{l=1}^d (1 + |t_l|)^{\nu - r} dt_l \leq C 2^{S_j \nu} \prod_{l=1}^d (1 + |w_l|)^{-1}. \tag{41} \]
Now we consider the case where there exists at least one \( w_l \) such that \( |w_l| \geq 1 \). We have
\[
(D_j \varphi)(w) = \prod_{l=1,|w_l| \leq 1}^{d} \int e^{-it_l w_l} \frac{F(\varphi)(t_l)}{F(g_l)(2^{j_l} t_l)} dt_l \times \prod_{l=1,|w_l| \geq 1}^{d} \int e^{-it_l w_l} \frac{F(\varphi)(t_l)}{F(g_l)(2^{j_l} t_l)} dt_l.
\]
For the left-hand product on \( |w_l| \leq 1 \) we use the result (41). Now let us consider the right-hand product with \( |w_l| \geq 1 \). We set in the sequel
\[
\eta(t_l) := \frac{F(\varphi)(t_l)}{F(g_l)(2^{j_l} t_l)}.
\]
We have
\[
\prod_{l=1,|w_l| \geq 1}^{d} \int e^{-it_l w_l} \frac{F(\varphi)(t_l)}{F(g_l)(2^{j_l} t_l)} dt_l = \prod_{l=1,|w_l| \geq 1}^{d} \int e^{-it_l w_l} \eta(t_l) dt_l.
\]
Since \( |\eta(t_l)| \to 0 \) when \( t_l \to \pm \infty \), an integration by part yields
\[
\int e^{-it_l w_l} \eta(t_l) dt_l = iw_l^{-1} \int e^{-it_l w_l} \eta_l(t_l) dt_l.
\]
Let us compute the derivative of \( \eta(t_l) \)
\[
\eta_l(t_l) = \frac{\partial}{\partial t_l} \left( \frac{F(\varphi)(t_l)}{F(g_l)(2^{j_l} t_l)} \right) = \frac{F'(g_l)(2^{j_l} t_l)F(\varphi)(t_l) - 2^{j_l} F'(g_l)(2^{j_l} t_l) \overline{\varphi}(t_l)}{(F(g_l)(2^{j_l} t_l))^2}.
\]
Using Lemma 8, (3) and (4)
\[
|\eta_l(t_l)| \leq \left| \frac{F'(g_l)(2^{j_l} t_l)}{F(g_l)(2^{j_l} t_l)} \right| + 2^{j_l} \left| \frac{F'(g_l)(2^{j_l} t_l) \overline{\varphi}(t_l)}{(F(g_l)(2^{j_l} t_l))^2} \right|
\]
\[
\leq C \left( (1 + |t_l|)^{-r} (1 + 2^{j_l} |t_l|)^{\nu} + 2^{j_l} (1 + 2^{j_l} |t_l|)^{-\nu - 1} (1 + |t_l|)^{-r} (1 + 2^{j_l} |t_l|)^{2\nu} \right)
\]
\[
\leq C \left( 2^{j_l \nu} (1 + |t_l|)^{-r} (2^{-j_l} + |t_l|)^{\nu} + 2^{j_l} (1 + 2^{j_l} |t_l|)^{-\nu - 1} (1 + |t_l|)^{-r} \right)
\]
\[
\leq C \left( 2^{j_l \nu} (1 + |t_l|)^{-r} (2^{-j_l} + |t_l|)^{\nu} + 2^{j_l \nu} (2^{-j_l} + |t_l|)^{-\nu - 1} (1 + |t_l|)^{-r} \right)
\]
\[
\leq C 2^{j_l \nu} \left( (1 + |t_l|)^{-r} (2^{-j_l} + |t_l|)^{\nu} + (2^{-j_l} + |t_l|)^{-\nu - 1} (1 + |t_l|)^{-r} \right).
\]
Therefore,
\[
\left| \int e^{-it_l w_l} \eta_l(t_l) dt_l \right|
\]
\[
\leq |w_l|^{-1} \int |\eta_l(t_l)| dt_l
\]
\[
\leq C |w_l|^{-1} 2^{j_l \nu} \int \left( (1 + |t_l|)^{-r} (2^{-j_l} + |t_l|)^{\nu} + (2^{-j_l} + |t_l|)^{-\nu - 1} (1 + |t_l|)^{-r} \right) dt_l
\]
\[
\leq C |w_l|^{-1} 2^{j_l \nu} (D_4 + D_2 + D_3),
\]
with $D_1$, $D_2$ and $D_3$ defined below.

$D_1 := \int_{|t_l| \leq 2^{-j_l}} ((1 + |t_l|)^{-r} (2^{-j_l} + |t_l|)^\nu + (2^{-j_l} + |t_l|)^{\nu-1}(1 + |t_l|)^{-r}) \, dt_l$

$\leq C \int_{|t_l| \leq 2^{-j_l}} ((2^{-j_l} + |t_l|)^\nu + (2^{-j_l} + |t_l|)^{\nu-1}) \, dt_l$

$\leq C 2^{-j_l(2^{-\nu})} + 2^{-j_l(\nu-1)}$

$\leq C$.

$D_2 := \int_{2^{-j_l} \leq |t_l| \leq 1} ((1 + |t_l|)^{-r} (2^{-j_l} + |t_l|)^\nu + (2^{-j_l} + |t_l|)^{\nu-1}(1 + |t_l|)^{-r}) \, dt_l$

$\leq C \int_{2^{-j_l} \leq |t_l| \leq 1} ((2^{-j_l} + |t_l|)^\nu + (2^{-j_l} + |t_l|)^{\nu-1}) \, dt_l$

$\leq C \int_{1}^{2^{j_l}} ((2^{-j_l} + 2^{-j_l}s)^\nu + (2^{-j_l} + 2^{-j_l}s)^{\nu-1})2^{-j_l} \, ds$

$\leq C 2^{-j_l(\nu+1)} \int_{1}^{2^{j_l}} s^\nu \, ds + C 2^{-j_l\nu} \int_{1}^{2^{j_l}} s^{\nu-1} \, ds$

$\leq C$,

as soon as $\nu > 0$.

$D_3 := \int_{|t_l| \geq 1} ((1 + |t_l|)^{-r} (2^{-j_l} + |t_l|)^\nu + (2^{-j_l} + |t_l|)^{\nu-1}(1 + |t_l|)^{-r}) \, dt_l$

$\leq C \int_{|t_l| \geq 1} (|t_l|^{\nu-r} + |t_l|^{\nu-1-r}) \, dt_l$

$\leq C$,

since $\nu - r < -1$.

When $\nu = 0$ we still have

$$\left| \int e^{-it_l w_l \eta_l(t_l)} dt_l \right| \leq C |w_l|^{-1} 2^{j_l \nu} = C |w_l|^{-1}.$$ 

Indeed when $\nu = 0$

$$\eta_l(t_l) = \overline{F(\varphi)}(t_l),$$

and

$$\left| iw_l^{-1} \int e^{-it_l w_l \eta_l^l(t_l)} dt_l \right| = \left| iw_l^{-1} \int e^{-it_l w_l \overline{F(\varphi)}(t_l)} dt_l \right|$$

$$\leq |w_l|^{-1} \int \left| \overline{F(\varphi)}(t_l) \right| \, dt_l$$

$$\leq C |w_l|^{-1} \int (1 + |t|)^{-r} \, dt < C |w_l|^{-1},$$

using Lemma 8 and $r \geq 2$. 

\qed
**Lemma 10.** There exist constants $R_{10}$ depending on $s, \mathcal{m}, \phi, c_g, C_g$ and $R_{11}$ depending on $\phi, c_g, C_g$ such that

$$\sigma_j^2 \leq R_{10}2^{S_j(2^j+1)}, \quad \|T_j\|_{\infty} \leq R_{11}2^{S_j(\nu+1)}.$$ 

**Proof.** We have

$$\sigma_j^2 = \text{Var}(U_j(Y_1, W_1)) \leq \mathbb{E} \left[ U_j(Y_1, W_1)^2 \right] = \mathbb{E} \left[ Y_1 \sum_k (D_j\varphi)_{j,k}(W_1)\varphi_{jk}(x) \right]^2 = \mathbb{E} \left[ (m(X_1) + \varepsilon_1) \sum_k (D_j\varphi)_{j,k}(W_1)\varphi_{jk}(x) \right]^2 \leq 2(\|m\|_\infty^2 + \sigma_j^2) \mathbb{E} \left[ \sum_k (D_j\varphi)_{j,k}(W_1)\varphi_{jk}(x) \right]^2 \leq 2(\|m\|_\infty^2 + \sigma_j^2) \int \left| \sum_k (D_j\varphi)_{j,k}(w)\varphi_{jk}(x) \right|^2 f_W(w)dw \leq 2(\|m\|_\infty^2 + \sigma_j^2)\|f_X\|_{\infty} \int 2^{S_j} \left| \sum_k (D_j\varphi)(2^jw - k)\varphi_{jk}(x) \right|^2 dw.$$

Now making the change of variable $z = 2^jw - k$, we get using Lemma 7 and Lemma 9 to bound $(D_j\varphi)(z)$

$$\sigma_j^2 \leq 2(\|m\|_\infty^2 + \sigma_j^2)\|f_X\|_{\infty} \int \left| \sum_k (D_j\varphi)(z)\varphi_{jk}(x) \right|^2 dz \leq C \int 2^{2S_j\nu} \prod_{i=1}^d \frac{1}{(1+|z_i|)^2} \left( \sum_k |\varphi_{jk}(x)| \right)^2 dz \leq R_{10}2^{S_j(2^j+1)},$$

where $R_{10}$ is a constant depending on $s, m, \phi, c_g, C_g$. This gives the bound for $\sigma_j^2$.

For $\|T_j\|_{\infty}$, using again Lemma 7 and Lemma 9, we have

$$\|T_j\|_{\infty} \leq \max_k \| (D_j\varphi)_{j,k} \|_{\infty} \sum_k |\varphi_{jk}(x)| \leq 2^{S_j} \| (D_j\varphi) \|_{\infty} \sum_k |\varphi_{jk}(x)| \leq R_{11}2^{S_j(\nu+1)},$$

where $R_{11}$ is a constant depending on $\phi, c_g, C_g$. \qed
