Irreducibility of some spectral determinants

Alexandre Eremenko* and Andrei Gabrielov†

April 10, 2009

Abstract

This is a complement to our paper arXiv:0802.1461. We study irreducibility of spectral determinants of some one-parametric eigenvalue problems in dimension one with polynomial potentials.

We consider eigenvalue problems of the type

$$-y'' + P(\alpha, z)y = \lambda y,$$

with the boundary condition that $y(z) \to 0$ along appropriately chosen paths in the complex plane (for example, at $\pm \infty$ on the real line). The potential $P$ is a polynomial in the independent variable $z$ depending on a complex parameter $\alpha$. The problems we consider have discrete spectra for all complex $\alpha$. The dependence of the eigenvalues on $\alpha$ is described by the equation

$$F(\alpha, \lambda) = 0,$$

where $F$ is an entire function of two variables which is called the spectral determinant. We study irreducibility of the spectral determinant for certain eigenvalue problems that occur in quantum mechanics.

Problems of this type were considered for the first time in [7, 8] for the case of Mathieu equation with the boundary conditions on a finite interval. We refer to [9, 2, 3, 4] for further development.

Our research was stimulated by the paper of Bender and Wu who discovered in [1] that the spectral determinant of the even quartic oscillator

*Supported by NSF grant DMS-0555279.
†Supported by NSF grant DMS-0801050.
has exactly two irreducible components. In our paper [5] we gave a complete rigorous proof of this fact. It was mentioned in [5] that our method applies to several other one-parametric families of eigenvalue problems, and the purpose of the present paper is to give some details of these applications.

We begin with a sketch of the main result of [5] referring to that paper for complete details.

Even quartic oscillator

1. Eigenvalue problem for the even quartic oscillator:

$$-y'' + (z^4 + \alpha z^2)y = \lambda y,$$

$$y(\pm \infty) = 0 \text{ on the real line,}$$

where $\alpha$ is a complex parameter.

The spectrum is discrete, infinite, simple.

$$Z = \{(\alpha, \lambda) \in \mathbb{C}^2 : \lambda \text{ is an eigenvalue of (1), (2)}\}$$

is an analytic subset of $\mathbb{C}^2$.

**Theorem 1** The set $Z$ consists of two irreducible components: one for even eigenfunctions, another for odd ones. These irreducible components are also connected components. Moreover, the set $Z$ is non-singular.

2. Parametrization of the set $Z$.

Let $G$ be the set of all odd meromorphic functions $f$ such that $f(z) \to 0$ as $z \to \pm \infty$ on the real line, and the Schwarzian

$$S_f = \frac{f'''}{f'} - \frac{3}{2} \left(\frac{f''}{f'}\right)^2$$

is a polynomial of degree 4 with leading coefficient $-2$:

$$-\frac{1}{2} S_f(z) = z^4 + \alpha z^2 - \lambda.$$

We have a map $\Phi : G \to \mathbb{C}^2$, $f \mapsto (\alpha, \lambda)$. 

2
Proposition 1  \( \Phi \) maps \( G \) to \( Z \) surjectively.

Remark 1  If we define the equivalence relation by \( f_1 \sim f_2 \) if \( f_1 = cf_2 \) then \( \tilde{\Phi} : G/\sim \to Z \) is a biholomorphic parametrization.

3. Sketch of the proof. \( f = y/y_1 \) where \( y \) is an eigenfunction (it is always even or odd), and \( y_1 \) a linearly independent solution of opposite parity. In the opposite direction: \( y_1 = 1/\sqrt{f} \), \( y = fy_1 \).

\[
f(z) \to 0, \quad |z| \to \infty \quad \text{on the real axis}
\]
\[
\iff \quad y \text{ is subdominant in } S_0, S_3
\]
\[
\iff \quad y \text{ is an eigenfunction}
\]
\[
\iff \quad \lambda \text{ is an eigenvalue.}
\]

Fig 1. Stokes sectors

4. Deformation of functions in \( G \).
\( f \in G \) has no critical points: \( f' = (y'y_1 - yy_1')/y_1^2 \) so \( f'(z) \neq 0 \) and the poles are simple.
$f$ has 6 asymptotic tracts corresponding to the Stokes sectors: $f(z) \to w_j$ in $S_j$.

Thus

$$f : \mathbb{C} \setminus f^{-1}(\{w_0, \ldots, w_5\}) \to \mathbb{C} \setminus \{w_0, \ldots, w_5\}$$

is an unramified covering.

**Proposition 2** Let $f_0 \in G$, and let $w_j(t)$ be a centrally symmetric deformation of the asymptotic values such that

$$w_j(0) \neq w_k(0) \implies w_j(t) \neq w_k(t), \quad t \in [0, 1].$$

Then there exists a deformation $f_t \in G$ for $t \in [0, 1]$ such that $f_t(z) \to w_j(t)$ in $S_j$.

5. Sketch of the proof. Let $\psi_t : \overline{\mathbb{C}} \to \overline{\mathbb{C}}$ be odd diffeomorphisms, $\psi_t(w_j(0)) = w_j(t)$. Then there exist odd diffeomorphisms $\phi_t : \mathbb{C} \to \mathbb{C}$ such that $g_t = \psi_t \circ f_0 \circ \phi_t$ are meromorphic functions in $\mathbb{C}$ (Nevanlinna, 1930). These functions have no critical points and 6 asymptotic tracts with asymptotic values $w_j(t)$.

For every meromorphic function with no critical points and $q$ asymptotic tracts, the Schwarzian $S_f$ is a polynomial of degree $q - 2$ (Nevanlinna, 1930). Putting $f_t(z) = g(c_t z)$ we make $-(1/2) S_f$ monic; it is even because $f$ is odd.

6. We may assume that

$$(w_0, w_1, w_2, w_3, w_4, w_5) = (0, i, 1, 0, -i, -1).$$

How to describe all $f \in G$ with such asymptotic values?

Let $\Psi_f = f^{-1}(\Psi_0)$, where $\Psi_0$ is the following cell decomposition of the Riemann sphere:
Fig 2. Cell decomposition $\Psi_0$.

The next figure shows how the preimage of $\Psi_0$ may look.
Fig 3. Cell decomposition $\Psi_f$.

Faces of $\Psi_f$ are labeled by asymptotic values. Removing loops and replacing multiple edges of $\Psi_f$ by simple edges, we obtain a tree $T$. This tree has 6 faces and faces labeled 0 cannot have a common boundary edge. It is possible to classify all such trees.
Fig 4. Classification of trees: $A_k : k \geq 0$, $D_{k,l} : k \geq 0, l \geq 1$, $E_{k,l} : k \geq 1, l \geq 0$. 
Fig 5. Additional patterns that occur if the cyclic order of the loops of $\Phi_0$ is opposite to the cyclic order of asymptotic tracts in $\mathbb{C}$. 
Proposition 2 implies that we can continuously deform the asymptotic values of a function in \( G \). We consider such deformations that the configuration of 5 asymptotic values describes a closed loop in the space of 5-point configurations symmetric with respect to the origin, and the asymptotic values \( i \) and \(-i\) are interchanged. Then we compute the action of these deformations on our cell decompositions of the plane, and conclude that there are exactly two orbits.

Fig 6. Paths \( s_0 \) and \( s_\infty \) used in the deformation of \( \Psi_0 \).
Fig 7. Action of $s_0$ on $\Psi_0$. The new loops are expressed in terms of the old ones by the formulas

$$\hat{\gamma}_i = (\gamma_1)^{-1}\gamma_i\gamma_1,$$
$$\hat{\gamma}_1 = \gamma_1,$$
$$\hat{\gamma}_{-i} = (\gamma_{-1})^{-1}\gamma_{-i}\gamma_{-1},$$
$$\hat{\gamma}_{-1} = \gamma_{-1}.$$
Fig 8. Action of $s_\infty$ on $\Psi_0$. The new loops are expressed by the formulas

\[
\hat{\gamma}_i = \gamma_i, \quad \hat{\gamma}_1 = (\gamma_{-i})^{-1}\gamma_1\gamma_{-i},
\]

\[
\hat{\gamma}_{-i} = \gamma_{-i}, \quad \hat{\gamma}_{-1} = (\gamma_i)^{-1}\gamma_{-1}\gamma_i.
\]
Fig 9. Example. Transformation of $A_1$ to $Q_{1,0}$ by the action of $s_0$. 
Fig 10. Monodromy action on the even part of $G$. 
Fig 11. Monodromy action on the odd part of $G$. 
This proof can be generalized to several other eigenvalue problems with polynomial potentials depending on one parameter.

Meromorphic functions in the plane of finite order, without critical points are called Nevanlinna functions.

This class of functions coincides with solutions of Schwarz differential equations

\[
\frac{f'''}{f'} - \frac{3}{2} \left( \frac{f''}{f'} \right)^2 = P, 
\]

where \( P \) is a polynomial. The order of growth of \( f \) equals \((\deg P)/2 + 1\), and \( f \) has exactly \((\deg P) + 2\) asymptotic tracts.

The general solution of the Schwarz differential equation is a ratio of two linearly independent solutions of the linear differential equation

\[
y'' + \frac{1}{2} Py = 0. 
\]

A Nevanlinna function is determined, up to an affine change of the independent variable, by its asymptotic values and by certain combinatorial information— topology of the cell decomposition of the plane obtained as the preimage of a cell decomposition of the Riemann sphere each of whose faces contains one asymptotic value. Two cell decompositions of the plane are equivalent if they can be obtained one from another by a homeomorphism of the plane preserving orientation.

Our proofs in all cases follow the same pattern. We parametrize the zero locus of the spectral determinant by a class of Nevanlinna functions. To study the irreducible components of this class, we move their asymptotic values to a convenient position. Then we describe all Nevanlinna functions of our class with these asymptotic values by some cell decompositions of the plane. All possible cell decompositions arising in a given problem can be classified by using some related trees. Then we study the monodromy action on the set of these trees.
Quasi-Exactly Solvable sextics (Turbiner-Ushveridze)

\[-y'' + (z^6 + 2\alpha z^4 + \{\alpha^2 - (4m + 2p + 3)\} z^2) y = \lambda y\]  \hspace{1cm} (3)

\[y(\pm\infty) = 0\] on the real line, \(m \geq 0, \ p \in \{0, 1\}\).  \hspace{1cm} (4)

There are \(m + 1\) “elementary” eigenfunctions

\[Q(z) \exp(-z^4/4 - \alpha z^2/2),\]

where \(Q\) is a polynomial of degree \(2m + p\).

Consider the set \(Z_{m,p}\) of pairs \((\alpha, \lambda)\) such that \(\lambda\) is an eigenvalue corresponding to an elementary eigenfunction of (3), (4).

**Theorem 2** For each \(m\) and \(p\) the set \(Z_{m,p}\) is irreducible.

Elementary eigenfunctions are distinguished by the property that asymptotic values in \(S_0, S_2, S_4, S_6\) are equal to zero. Thus we have 5 asymptotic values. Proposition 2 permits to move them to the points \((0, i, 0, 1, 0, -i, 0, -1)\), and we use the cell decomposition of the Riemann sphere shown in Fig. 2.

Applying the reduction procedure illustrated in Fig. 3, we obtain centrally symmetric trees with 8 ends, in which even-numbered faces are labeled by 0, and none of such two faces have a common boundary edge. Next we obtain a classification of such trees.
Fig S2. Classification of QES sextic trees
Fig S3. Non-tree QES sextic graphs
Fig S4. Monodromy action for an even QES sextic, \(m = 3, \ p = 0\)
Fig S5. Monodromy action for an odd QES sextic, $m = 2$, $p = 1$
Fig S6. Branching points for a QES sextic with $m = 10$, $p = 0$
Let $n = 4m + 2p + 3$. Then the quasi-exactly solvable equation (3) is related to

$$- y''(x) + [a^2 x^6 + 2ab x^4 + (b^2 - an)x^2]y(x) = \mu y(x)$$

by the scaling $z = a^{1/4} x$, $b = a^{1/2} \alpha$, $\lambda = a^{1/2} \mu$. To approximate the quartic potential $2x^4 + \beta x^2$ by the rescaled quasi-exactly solvable sextic potentials in (5) as $m \to \infty$, let

$$b = n^{1/3}(1 + sn^{-2/3}), \quad a = n^{-1/3}(1 + tn^{-2/3}).$$

Then

$$\alpha = b/a^{1/2} = n^{1/2}(1 + (s-t/2)n^{-2/3} + O(n^{-4/3}).$$

Substituting expression for $a$ and $b$ into (5), we get the potential

$$n^{-2/3}(1 + O(n^{-2/3})) x^6 + 2(1 + (s+t)n^{-2/3} + stn^{-4/3}) x^4 + ((2s - t) + s^2 n^{-2/3}) x^2.$$

Hence

$$\beta = 2s - t = 2(n^{-1/2} \alpha - 1)n^{2/3} + O(n^{-2/3}).$$

**PT-symmetric cubic** (Delabaere-Trinh)

Polynomial potential $P(z)$ is $PT$-symmetric if $P(-\bar{z}) = \overline{P(z)}$. 

Eigenvalue problem

\[-y'' + (iz^3 + i\alpha z) y = \lambda y, \quad (6)\]

\[y(\pm\infty) = 0 \text{ on the real line,} \quad (7)\]

is $PT$-symmetric for real $\alpha$.

Let $Z$ be the set of all pairs $(\alpha, \lambda)$ such that $\lambda$ is an eigenvalue of (6), (7).

**Theorem 3** The set $Z$ is irreducible.

![Stokes sectors for the cubic potential](image_url)

Fig C0. Stokes sectors for the cubic potential
Let $f$ be a Nevanlinna function with $q$ asymptotic values. Consider a cell decomposition of the sphere with two vertices which we denote by $\times$ and $\circ$, with $q$ edges each connecting these two vertices, and such that each of the faces contains exactly one asymptotic value. The $f$-preimage of such cell decomposition is called a line complex (see [6]). All possible line complexes of Nevanlinna functions can be simply characterized: they are bipartite graphs embedded in the plane such that the degree of each vertex is $q$ and all faces have either two or infinitely many boundary edges. Replacing multiple edges of a cell complex by single edges we obtain a tree. The line complex can be recovered from this tree.

These properties make line complexes very convenient. The reason why we used other cell decompositions of the sphere for quartics and sextics is that there are no line complexes for these cases having all symmetries present in the problems.

In the case of PT-symmetric cubic we can move the asymptotic values to the following positions: $(0, 1, -1, 0, \infty)$ (listed counterclockwise starting from $S_0$. The line complex is the preimage of the following cell decomposition of the Riemann sphere:

Quasi-Exactly Solvable quartics (Bender-Boettcher)

The problem

\[- y'' + (z^4 - 2\alpha z^2 - 2imz) y = \lambda z, \quad m \geq 1 \quad (8)\]

\[y(re^{i\theta}) \to 0 \text{ as } r \to \infty, \quad \theta \in \{-\pi/6, -\pi + \pi/6\} \quad (9)\]

is PT-symmetric for real \( \alpha \).

There are \( m \) “elementary” eigenfunctions

\[P(z) \exp(-iz^3/3 - ibz)\]

\( P \) polynomial of degree \( m - 1 \).

Let \( Z_m \) be the set of all pairs \((\alpha, \lambda)\) such that \( \lambda \) is an eigenvalue of (8), (9) corresponding to an elementary eigenfunction.

**Theorem 4** For each \( m \), the set \( Z_m \) is irreducible.

There are six Stokes sectors, with \( S_0 = \{ -\pi/3 < \arg z < 0 \} \) and the asymptotic values can be placed at the points \((0, -1, 0, 1, 0, \infty)\), listed anticlockwise, starting from \( S_0 \). The cell decomposition of the Riemann sphere is the same as in Fig. C1, and its preimage is a line complex. The associated trees have five ends, and the faces labeled with 0 have disjoint boundaries. Such trees are classified into types A, B and C. The deformation paths are the same as for the PT-symmetric cubic, Fig. C10.
