(Dated: October 29, 2019)
Abstract

A class of high-order canonical symplectic structure-preserving geometric algorithms are developed for high-quality simulations of the quantized Dirac-Maxwell theory based strong-field quantum electrodynamics (SFQED) and relativistic quantum plasmas (RQP) phenomena. With minimal coupling, the Lagrangian density of an interacting bispinor-gauge fields theory is constructed in a conjugate real fields form. The canonical symplectic form and canonical equations of this field theory are obtained by the general Hamilton’s principle on cotangent bundle. Based on discrete exterior calculus, the gauge field components are discreted to form a cochain complex, and the bispinor components are naturally discreted on a staggered dual lattice as different differential forms. With pull-back and push-forward gauge covariant derivatives, the discrete action is gauge invariant. A well-defined discrete canonical Poisson bracket generates a semi-discrete lattice canonical field theory (LCFT), which admits canonical symplectic form, unitary property, gauge symmetry and Poincaré invariance, which are good approximations of the original continuous geometric structures. The Hamiltonian splitting method, Cayley transformation and symmetric composition technique are introduced to construct a class of high-order numerical schemes for the semi-discrete LCFT. These schemes are fermion doubling free and locally unconditional stable, which also preserve the geometric structures. Equipped with statistically quantization-equivalent ensemble models of the Dirac vacuum and non-trivial plasma backgrounds, the schemes are expected to have excellent performance in secular simulations of relativistic quantum effects, where the numerical errors of conserved quantities are well bounded by very small values without coherent accumulation. The algorithms are verified in detail by numerical energy spectra. Real-time LCFT simulations are successfully implemented for the nonlinear Schwinger mechanism induced $e^{-}e^{+}$ pairs creation and vacuum Kerr effect, where the nonlinear and non-perturbative features captured by the solutions provide a complete strong-field physical picture in a very wide range, which open a new door toward high-quality simulations in SFQED and RQP fields.

I. INTRODUCTION

Quantum electrodynamics (QED) at extreme conditions is becoming more and more important, as the relativistic quantum effects are becoming dominant mechanism in many branches of modern physics. With the development of high power laser technology, e.g. chirped pulse amplification (CPA), the peak intensity above $10^{22} \text{ W} \cdot \text{cm}^{-2}$ is available by 1~10 PW lasers, which is far stronger than the direct ionization threshold of $10^{16} \sim 10^{18} \text{ W} \cdot \text{cm}^{-2} \[1, 2\]$. When the matter is exposed in such intense laser beams, strong ionization can be generated and large relativistic quantum plasmas (RQP) will be produced \[3–8\]. Next generation 10~PW laser projects, such as the extreme light infrastructure (ELI) and the high power laser energy research facility (HiPER), aimed to approach the Schwinger threshold of $10^{29} \text{ W} \cdot \text{cm}^{-2}$ or realize the fast ignition \[1, 2, 5\]. The Schwinger mechanism induced creation and following annihilation of fermion pairs play a fundamentally important role in modern high energy density physics (HEDP), astrophysics, and strong-field quantum electrodynamics (SFQED) \[3–5, 7–10\]. Although the direct experimental verification of electron-positron ($e^−e^+$) pair creation under the Schwinger limit in laboratory is still expected to realize in near future, the $e^−e^+$ RQP is already an important target for astronomical observers, such as the magnetosphere of an X-ray pulsar \[11–13\]. The typical magnetic field of X-ray pulsars is $10^{12} \text{ G}$, and the effective temperature of X-ray pulsars is 10 KeV. In such a environment, the magnetic energy approaches to the rest energies of electron and positron, and it is higher than the thermal energy. As a result, the relativistic quantum effects lead to anharmonic cyclotron absorption features observed in spectra of X-ray pulsars \[111, 114\]. Effective and accurate non-perturbative methods are needed in understanding these SFQED and RQP phenomena. Among a group of semi-analytical and numerical methods, the lattice quantum field theory (LQFT) is an advanced theoretical tool to study relativistic quantum effects both in vacuum and plasmas.

As a quantum gauge field theory on the discrete lattice in Euclidean space-time, the LQFT first developed by Wilson has been widely used in quantum chromodynamics (QCD) to describe the strong interactions, such as the quark confinement and the quark-gluon plasmas (QGP) \[15, 19\]. Based on numerical path integrals and large-scale Monte Carlo (MC) simulations, the lattice quantum chromodynamics (LQCD) brings many significant results, such as the QCD phase transition and the hadron spectroscopy \[18, 19\]. By using
the Schwinger-Keldysh time contours, the LQCD can even be expanded to simulate non-equilibrium statistical systems \cite{20,21}. The LQCD can not only capture the basic quantum loop effects, but also provide us with a well-defined non-perturbative theory of QCD \cite{19}. As a post-MC technique, the tensor network (TN) techniques provide an alternative approach to simulate the lattice gauge theories (LGT), which can be efficiently extended to real-time evolution of out-of-equilibrium systems \cite{22–26}. When it comes to phenomena with high occupation numbers and weak coupling, e.g. SFQED with non-trivial backgrounds and RQP, the classical relativistic field equations can be treated as good approximations to describe the dynamics of particles, where the quantum fluctuations can be introduced by constructing a statistically quantization-equivalent ensemble \cite{27–41}. Based on this real-time lattice quantum electrodynamics (LQED) method in classical statistic regime, some interesting phenomena have been numerically studied, such as the pair creation of fermions beyond the Schwinger limit \cite{33}, the real-time dynamics of string breaking \cite{32}, the chiral magnetic effects \cite{37}, and the $e^{-}e^{+}$ pair production in laser-plasma interactions (LPI) \cite{40}. The LGT simulations are even reconstructed to implement on optical lattice based quantum simulators in recent time, which show great vitality \cite{42,43}.

When implementing a real-time LQED simulation in classical statistic regime, a stable and high fidelity numerical algorithm is needed to obtain reliable and accurate results. When it comes to the $U(1)$ gauge field, there are many popular schemes for Maxwell’s equations, such as the finite-difference time-domain (FDTD) method, the finite-element (FE) method, and the method of moments (MoM) etc., which are widely used in computational electro-dynamics (CED) \cite{44–48}. When it comes to the bispinor field, the numerical calculations of Dirac equation may encounter more difficult, e.g. fermion doubling problem, which will bring pseudo-fermion modes on the lattice \cite{49}. There are several stable Dirac solvers, such as the time-splitting spectral (TSSM) method, quantum lattice Boltzmann (QLBM) technique, summation-by-parts-simultaneous approximation term (SBP-SAT) method, and time-dependent Galerkin (TDG) method etc \cite{50,61}. Although these algorithms have different advantages in part, an unified scheme with almost perfect performance is still a beautiful goal. Because of the nonlinearity and the multi-scale nature of the Dirac-Maxwell equations, high-quality simulations of real-time LQED face challenges. For instance, the numerical errors of conserved quantities can coherently accumulate, though these errors may be very small in each numerical step. The breakdown of conservation laws over a long
simulation time amounts to pseudophysics. The structure-preserving geometric algorithms first developed by Feng et al. for classical Hamiltonian systems have excellent performance in long-term simulations [62–72], which are widely used in many complex systems, especially in geophysics and plasma physics [73–86]. In this work, we construct a class of structure-preserving geometric algorithms for Dirac-Maxwell theory. The algorithms preserve the symplectic and unitary structures, admit the $U(1)$ gauge and Poincaré symmetries on the lattice, and are without fermion doubling, which provide a powerful numerical tool for Dirac-Maxwell theory based real-time LQED simulations.

In Sec.II a canonical field theory of Dirac-Maxwell systems is constructed in a conjugate real fields form to describe the fermion-photon interactions. The canonical symplectic form on cotangent bundle is obtained explicitly. In Sec.III a semi-discrete lattice canonical field theory (LCFT) is constructed via the discrete exterior calculus (DEC) [87–89], the pull-back and push-forward gauge covariant derivatives, and a discrete canonical Poisson bracket. The LCFT admits symplectic and unitary structures, and also admits $U(1)$ gauge and Poincaré symmetries on the lattice. In Sec.IV a class of high-order structure-preserving geometric algorithms are constructed for the LCFT. These schemes are fermion doubling free and locally unconditional stable, which also preserve the geometric structures and symmetries. An ensemble model based field quantization procedure is reconstructed to simulate the Dirac vacuum and RQP. In Sec.V the algorithms are detailedly verified and successfully used to simulate Schwinger mechanism induced $e^+e^-$ pairs creation and vacuum Kerr effect. Numerical results show good properties in secular simulations. In Sec.VI we give a brief discussion about the advantages and attentions in implementing a real-time LCFT simulation by our algorithms, and show the outlook of applications in SFQED and RQP researches.

II. CANONICAL FIELD THEORY OF THE DIRAC-MAXWELL SYSTEMS

A. Lagrangian field theory

The Lagrangian density of the Dirac-Maxwell theory based QED can be written as [90–94],

$$\mathcal{L} = \mathcal{L}_D + \mathcal{L}_M,$$

$$\mathcal{L}_D = \bar{\psi} \left( i \hbar c \partial - mc^2 \right) \psi,$$
\[ \mathcal{L}_M = -\frac{1}{16\pi} \mathcal{F}^{\mu\nu} \mathcal{F}_{\mu\nu}. \]  

Where the Dirac bispinor \( \psi \) is a 4 components complex field. With the Minkowski metric \( g^{\mu\nu} = g_{\mu\nu} = \text{diag}(+, -, -, -) \), the contravariant 4-vectors of coordinate and \( U(1) \) gauge field can be given as \( x^\mu = (ct, \mathbf{x}) \), \( A^\mu = (\phi, \mathbf{A}) \), and the Maxwell gauge field strength tensor \( \mathcal{F}^{\mu\nu} = \partial^\mu A^\nu - \partial^\nu A^\mu \). The Dirac conjugate bispinor \( \bar{\psi} = \psi^+ \gamma^0 \), where the superscript + means Hermitian and the 4 × 4 matrices \( \gamma^\mu \) belong to a Clifford algebra \( \{ \gamma^\mu, \gamma^\nu \} = 2g^{\mu\nu} \). With minimal coupling, the gauge covariant derivative \( D_\mu = \partial_\mu + i\frac{e}{\hbar c} A_\mu \), and the Feynman dagger \( \bar{\psi} = \gamma^\mu D_\mu \) means Dirac contraction, where the charge \( e \), reduced Planck constant \( \hbar \) and light speed \( c \) have their usual meanings. In the Dirac representation, the \( \gamma^\mu \) matrices are given as [93, 94],

\[ \gamma^0 = \begin{pmatrix} I_2 & 0_2 \\ 0_2 & -I_2 \end{pmatrix}, \quad \gamma^i = \begin{pmatrix} 0_2 & \hat{\sigma}_i \\ -\hat{\sigma}_i & 0_2 \end{pmatrix}. \]  

Where the Pauli matrices \( \hat{\sigma}_i \) have their usual forms,

\[ \hat{\sigma}_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \hat{\sigma}_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \hat{\sigma}_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \]  

The Dirac bispinor and it’s Hermitian can be rewritten in a conjugate real fields form as,

\[ \psi = \frac{1}{\sqrt{2\hbar}} \left( \psi_R + i\psi_I \right) = \frac{1}{\sqrt{2\hbar}} \begin{pmatrix} \psi_{1R} + i\psi_{1I} \\ \psi_{2R} + i\psi_{2I} \\ \psi_{3R} + i\psi_{3I} \\ \psi_{4R} + i\psi_{4I} \end{pmatrix}, \]  

\[ \psi^+ = \frac{1}{\sqrt{2\hbar}} \left( \psi_R^T - i\psi_I^T \right) = \frac{1}{\sqrt{2\hbar}} \begin{pmatrix} \psi_{1R} - i\psi_{1I} \\ \psi_{2R} - i\psi_{2I} \\ \psi_{3R} - i\psi_{3I} \\ \psi_{4R} - i\psi_{4I} \end{pmatrix}^T. \]  

By introducing the Dirac matrices [93, 94],

\[ \alpha_i = \gamma^0 \gamma^i = \begin{pmatrix} 0_2 & \hat{\sigma}_i \\ \hat{\sigma}_i & 0_2 \end{pmatrix}, \quad \beta = \gamma^0 I_4 = \gamma^0, \]
we can rewrite the Lagrangian density \([1]\) as,

\[
L = \frac{1}{2\hbar} \left( \psi_R^T - i\psi_I^T \right) \left( i\hbar \frac{\partial}{\partial t} + ihc\alpha \cdot \nabla - e\phi + e\alpha \cdot A - \beta mc^2 \right) \left( \psi_R + i\psi_I \right) + \frac{1}{8\pi} (E^2 - B^2)
\]

\[
= \frac{1}{2} \left( \psi_I^T \frac{\partial}{\partial t} \psi_R - \psi_R^T \frac{\partial}{\partial t} \psi_I \right) + i \frac{1}{2} \left( \psi_I^T \frac{\partial}{\partial t} \psi_R + \psi_R^T \frac{\partial}{\partial t} \psi_I \right) - \frac{1}{2\hbar} (\psi_R^T - i\psi_I^T) \hat{H} (\psi_R + i\psi_I)
\]

\[
+ \frac{1}{8\pi} (E^2 - B^2).
\]

(9)

Where \(E = -\dot{A}/c - \nabla \phi\) and \(B = \nabla \times A\) are electric and magnetic strengths of the \(U(1)\) gauge field, and the superscript \(\cdot\) means derivative with respect to time. \(\hat{H} = \hat{H}_R + i\hat{H}_I = -ihc\alpha \cdot \nabla - e\alpha \cdot A + e\phi + \beta mc^2\) is the Hamiltonian operator of the Dirac equation, which can be given as,

\[
\hat{H}_R = \begin{pmatrix}
    e\phi + mc^2 & 0 & -eA_z & -eA_x - hc\partial_y \\
    0 & e\phi + mc^2 & -eA_x + hc\partial_y & eA_z \\
    -eA_z & -eA_x - hc\partial_y & e\phi - mc^2 & 0 \\
    -eA_x + hc\partial_y & eA_z & 0 & e\phi - mc^2
\end{pmatrix},
\]

(10)

\[
\hat{H}_I = \begin{pmatrix}
    0 & 0 & -hc\partial_z & eA_y - hc\partial_x \\
    0 & 0 & -eA_y - hc\partial_x & hc\partial_z \\
    -hc\partial_z & eA_y - hc\partial_x & 0 & 0 \\
    -eA_y - hc\partial_x & hc\partial_z & 0 & 0
\end{pmatrix}.
\]

(11)

By substituting Eqs. (10)-\(11\) into Eq. (9) and integrating it in full Minkowski space-time manifold, we obtain the action functional \(S = \int_T L dt = \int_T \int_V L d^4x\). Where the Lagrangian functional can be given as,

\[
L = \int_V L d^3x\]

\[
= \int_V \left[ \frac{1}{2} \left( \psi_I^T \dot{\psi}_R - \psi_R^T \dot{\psi}_I \right) - \frac{1}{2\hbar} \left( \psi_I^T \dot{\psi}_R + \psi_R^T \dot{\psi}_I - \psi_R^T \dot{\psi}_R \psi_I^T \dot{\psi}_I + \psi_I^T \dot{\psi}_I \psi_R^T \dot{\psi}_R \right) \right] d^3x.
\]

(12)

On the tangent bundle \(TG\) of the configuration manifold \(G = (\psi_R, \psi_I, A, \phi)\), the Hamilton’s principle \(\delta S = 0\) gives rise to the classical dynamical equations of the fields,

\[
\hbar \frac{\partial}{\partial t} \begin{pmatrix}
    \psi_R \\
    \psi_I
\end{pmatrix} = \begin{pmatrix}
    \dot{\hat{H}}_I & \dot{\hat{H}}_R \\
    -\dot{\hat{H}}_R & \dot{\hat{H}}_I
\end{pmatrix} \begin{pmatrix}
    \psi_R \\
    \psi_I
\end{pmatrix},
\]

(13)
\[
\frac{1}{c^2} \ddot{\mathbf{A}} + \nabla \times \nabla \times \mathbf{A} + \frac{1}{c} \nabla \phi = \frac{4\pi}{c} \mathbf{J}.
\]

(14)

Where the bilinear form \( \mathbf{J} = e c \psi^+ \alpha \psi \) is the Dirac current density [94], and the gauge field components are restricted by the Gauss’s law \( c \nabla^2 \phi + \nabla \cdot \mathbf{A} = -4\pi e c \psi^+ \psi \).

### B. Hamiltonian field theory

The cotangent bundle of the configuration manifold \( G \) can be defined as \( T^*G = (\psi_R, \psi_I, \mathbf{A}, \phi, \delta L/\delta \psi_R, \delta L/\delta \psi_I, \delta L/\delta \mathbf{A}, \delta L/\delta \phi) \), where the variational derivatives of Lagrangian functional with respect to field components are given as,

\[
\frac{\delta L}{\delta \psi_R} = \frac{1}{2} \psi_I, \quad \frac{\delta L}{\delta \psi_I} = -\frac{1}{2} \psi_R,
\]

(15)

\[
\mathbf{Y} = \frac{\delta L}{\delta \mathbf{A}} = \frac{1}{4\pi c^2} \mathbf{A} + \frac{1}{4\pi c} \nabla \phi, \quad \frac{\delta L}{\delta \phi} = 0.
\]

(16)

The Hamiltonian functional \( H \) can be obtained via the Legendre transformation of \( L \), which is a map \( TG \rightarrow T^*G \),

\[
H = \int_V \left[ \left( \frac{\delta L}{\delta \psi_R} \right)^T \psi_R + \left( \frac{\delta L}{\delta \psi_I} \right)^T \psi_I + \frac{\delta L}{\delta \mathbf{A}} \cdot \dot{\mathbf{A}} \right] d^3x - L
\]

\[
= \int_V \left\{ \frac{1}{2\hbar} \left( \psi_R^T \dot{\mathbf{H}}_R \psi_R + \psi_I^T \dot{\mathbf{H}}_R \psi_I - \psi_R^T \dot{\mathbf{H}}_I \psi_I + \psi_I^T \dot{\mathbf{H}}_I \psi_R \right)
\]

\[
+ \frac{1}{8\pi} \left[ 16\pi^2 c^2 \mathbf{Y}^2 - 8\pi c \mathbf{Y} \cdot \nabla \phi \right] \right\} d^3x.
\]

(17)

On the cotangent bundle \( T^*G \), we can obtain a 2-form field,

\[
\Omega = -d \left[ \left( \frac{\delta L}{\delta \psi_R} \right)^T d\psi_R + \left( \frac{\delta L}{\delta \psi_I} \right)^T d\psi_I + \frac{\delta L}{\delta \mathbf{A}} \cdot d\mathbf{A} \right]
\]

\[
= \sum_{i=1}^4 d\psi_{iR} \wedge d\psi_{iI} + \sum_{i=1}^3 dA_i \wedge dY_i,
\]

(18)

which is obviously exact and closed, where \( d \) is the exterior derivative operator. The 2-form \( \Omega \) is a canonical symplectic form which can be used to construct a Poisson algebra,

\[
\{F, G\} = \int_V \left[ \left( \frac{\delta F}{\delta \psi_R} \right)^T \frac{\delta F}{\delta \mathbf{A}}, \left( \frac{\delta F}{\delta \psi_I} \right)^T \frac{\delta F}{\delta \mathbf{Y}} \right] \Omega \left[ \left( \frac{\delta G}{\delta \psi_R} \right)^T \frac{\delta G}{\delta \mathbf{A}}, \left( \frac{\delta G}{\delta \psi_I} \right)^T \frac{\delta G}{\delta \mathbf{Y}} \right]^T d^3x
\]

\[
= \int_V \left[ \sum_{i=1}^4 \left( \frac{\delta F}{\delta \psi_{iR}} \frac{\delta G}{\delta \psi_{iR}} - \frac{\delta G}{\delta \psi_{iR}} \frac{\delta F}{\delta \psi_{iI}} \right) + \frac{\delta F}{\delta \mathbf{A}} \cdot \frac{\delta G}{\delta \mathbf{Y}} - \frac{\delta G}{\delta \mathbf{A}} \cdot \frac{\delta F}{\delta \mathbf{Y}} \right] d^3x.
\]

(19)
Where $F$ and $G$ are arbitrary functionals on $T^*G$. The dynamical equations of a field theory with canonical symplectic structure can be generated by the Hamiltonian functional of this field theory,

$$\hat{F} = \{F, H\}. \quad (20)$$

By taking the total variation of the Hamiltonian functional (17) with fixed boundary, we obtain,

$$\delta H = \int_V \left\{ \frac{1}{\hbar} \left[ (e\phi + mc^2) \psi_{1R} - eA_x \psi_{4R} - eA_y \psi_{4I} - eA_z \psi_{3R} - hc(-\partial_x \psi_{4I} + \partial_y \psi_{4R} - \partial_z \psi_{3I}) \right] \delta \psi_{1R} \\
+ \frac{1}{\hbar} \left[ (e\phi + mc^2) \psi_{2R} - eA_x \psi_{3R} + eA_y \psi_{3I} + eA_z \psi_{4R} - hc(-\partial_x \psi_{3I} - \partial_y \psi_{3R} + \partial_z \psi_{4I}) \right] \delta \psi_{2R} \\
+ \frac{1}{\hbar} \left[ (e\phi - mc^2) \psi_{3R} - eA_x \psi_{2R} - eA_y \psi_{2I} - eA_z \psi_{1R} - hc(-\partial_x \psi_{2I} + \partial_y \psi_{2R} - \partial_z \psi_{1I}) \right] \delta \psi_{3R} \\
+ \frac{1}{\hbar} \left[ (e\phi - mc^2) \psi_{4R} - eA_x \psi_{1R} + eA_y \psi_{1I} + eA_z \psi_{2R} - hc(-\partial_x \psi_{1I} - \partial_y \psi_{1R} + \partial_z \psi_{2I}) \right] \delta \psi_{4R} \\
+ \frac{1}{\hbar} \left[ (e\phi + mc^2) \psi_{1I} - eA_x \psi_{4I} + eA_y \psi_{4R} - eA_z \psi_{3I} - hc(\partial_x \psi_{4R} + \partial_y \psi_{4I} + \partial_z \psi_{3R}) \right] \delta \psi_{1I} \\
+ \frac{1}{\hbar} \left[ (e\phi + mc^2) \psi_{2I} - eA_x \psi_{3I} - eA_y \psi_{3R} + eA_z \psi_{4I} - hc(\partial_x \psi_{3R} - \partial_y \psi_{3I} - \partial_z \psi_{4I}) \right] \delta \psi_{2I} \\
+ \frac{1}{\hbar} \left[ (e\phi - mc^2) \psi_{3I} - eA_x \psi_{2I} + eA_y \psi_{2R} - eA_z \psi_{1I} - hc(\partial_x \psi_{2R} + \partial_y \psi_{2I} + \partial_z \psi_{1I}) \right] \delta \psi_{3I} \\
+ \frac{1}{\hbar} \left[ (e\phi - mc^2) \psi_{4I} - eA_x \psi_{1I} + eA_y \psi_{1R} + eA_z \psi_{2I} - hc(\partial_x \psi_{1R} + \partial_y \psi_{1I} - \partial_z \psi_{2I}) \right] \delta \psi_{4I} \\
+ \left[ -\frac{1}{c} \mathbf{J} + \frac{1}{4\pi} \nabla \times \nabla \times \mathbf{A} \right] \cdot \delta \mathbf{A} + (4\pi e^2 \mathbf{Y} - c \nabla \phi) \cdot \delta \mathbf{Y} - c \nabla \cdot \mathbf{Y} \delta \phi \right\} dx. \quad (21)$$

Where the Dirac current density can be expanded as,

$$\mathbf{J} = \frac{ec}{\hbar} \left( \begin{array}{c} \psi_{1R} \psi_{4R} + \psi_{1I} \psi_{4I} + \psi_{2R} \psi_{3R} + \psi_{2I} \psi_{3I} \\
\psi_{1R} \psi_{4I} + \psi_{1I} \psi_{4R} + \psi_{2R} \psi_{3I} - \psi_{2I} \psi_{3R} \\
\psi_{1R} \psi_{3R} + \psi_{1I} \psi_{3I} - \psi_{2R} \psi_{4R} - \psi_{2I} \psi_{4I} \end{array} \right) = ec\psi^+ \alpha \psi. \quad (22)$$

By substituting Eqs. (21), (22) into Eq. (20), we obtain the canonical equations of the Dirac-Maxwell fields theory as,

$$\psi_{1R} = \{\psi_{1R}, H\}$$
$$= \frac{1}{\hbar} \left[ (e\phi + mc^2) \psi_{1I} - eA_x \psi_{4I} + eA_y \psi_{4R} - eA_z \psi_{3I} - hc(\partial_x \psi_{4R} + \partial_y \psi_{4I} + \partial_z \psi_{3R}) \right] \quad (23)$$

$$\psi_{2R} = \{\psi_{2R}, H\}$$
$$= \frac{1}{\hbar} \left[ (e\phi + mc^2) \psi_{2I} - eA_x \psi_{3I} - eA_y \psi_{3R} + eA_z \psi_{4I} - hc(\partial_x \psi_{3R} - \partial_y \psi_{3I} - \partial_z \psi_{4I}) \right] \quad (24)$$
\[ \dot{\psi}_{3R} = \{\psi_{3R}, H\} \]
\[ = \frac{1}{\hbar} \left[ (e\phi - mc^2) \psi_{3I} - eA_x\psi_{2I} + eA_y\psi_{2R} - eA_z\psi_{1I} - \hbar c (\partial_x\psi_{2R} + \partial_y\psi_{2I} + \partial_z\psi_{1R}) \right] \] (25)

\[ \dot{\psi}_{4R} = \{\psi_{4R}, H\} \]
\[ = \frac{1}{\hbar} \left[ (e\phi - mc^2) \psi_{4I} - eA_x\psi_{1I} - eA_y\psi_{1R} + eA_z\psi_{2I} - \hbar c (\partial_x\psi_{1R} - \partial_y\psi_{1I} - \partial_z\psi_{2R}) \right] \] (26)

\[ \dot{\psi}_{1I} = \{\psi_{1I}, H\} \]
\[ = -\frac{1}{\hbar} \left[ (e\phi + mc^2) \psi_{1R} - eA_x\psi_{4I} - eA_y\psi_{3I} - eA_z\psi_{3R} - \hbar c (-\partial_x\psi_{4I} + \partial_y\psi_{3I} + \partial_z\psi_{3R}) \right] \] (27)

\[ \dot{\psi}_{2I} = \{\psi_{2I}, H\} \]
\[ = -\frac{1}{\hbar} \left[ (e\phi + mc^2) \psi_{2R} - eA_x\psi_{3R} + eA_y\psi_{3I} + eA_z\psi_{4I} - \hbar c (-\partial_x\psi_{3I} - \partial_y\psi_{3R} + \partial_z\psi_{4I}) \right] \] (28)

\[ \dot{\psi}_{3I} = \{\psi_{3I}, H\} \]
\[ = -\frac{1}{\hbar} \left[ (e\phi - mc^2) \psi_{3R} - eA_x\psi_{2R} - eA_y\psi_{2I} - eA_z\psi_{1R} - \hbar c (-\partial_x\psi_{2I} + \partial_y\psi_{2R} - \partial_z\psi_{1I}) \right] \] (29)

\[ \dot{\psi}_{4I} = \{\psi_{4I}, H\} \]
\[ = -\frac{1}{\hbar} \left[ (e\phi - mc^2) \psi_{4R} - eA_x\psi_{1R} + eA_y\psi_{1I} + eA_z\psi_{2R} - \hbar c (-\partial_x\psi_{1I} - \partial_y\psi_{1R} + \partial_z\psi_{2I}) \right] \] (30)

\[ \dot{A} = \{A, H\} = 4\pi c^2 Y - c \nabla \phi, \] (31)

\[ \dot{Y} = \{Y, H\} = -\frac{1}{4\pi} \nabla \times \nabla \times A + \frac{1}{c} J. \] (32)

The canonical equations (23)-(32) equal to the dynamical equations (13)-(14), which means that the Hamiltonian field theory on \( T^*G \) is an equivalent theory to the Lagrangian field theory on \( TG \), both of which describe the intrinsic geometric structures of the interacting particles.

C. Gauge and Poincaré invariances

The QED is \( U(1) \) gauge and Poincaré invariant. Based on the Noether’s theorem, the canonical field theory constructed in Sec II for Dirac-Maxwell systems admits charge, energy-momentum and angular momentum conservation laws \([90, 91] \).
The $U(1)$ gauge symmetry means that the action and dynamical equations are invariant under the $U(1)$ gauge transformation,

$$ (A^\mu, \psi, \psi^+) \rightarrow (A^\mu + \partial^\mu \theta, \psi e^{i \frac{\theta}{\hbar c}} \psi^+ e^{-i \frac{\theta}{\hbar c}}), $$

where the gauge parameter $\theta$ is an arbitrary scalar field. It is convenient to verify the $U(1)$ gauge symmetry of the canonical field theory by substituting Eq. (33) into the Lagrangian density (9) or canonical equations (23)-(32). With an infinitesimal gauge transformation $\delta(A^\mu, \psi, \psi^+) = (\partial^\mu \theta, i \frac{\theta}{\hbar c} \psi, -i \frac{\theta}{\hbar c} \psi^+)$ and using the dynamical equations (13)-(14), we can obtain the charge conservation law via $\delta S = 0$,

$$ \left( \frac{\delta S}{\delta \psi} \right)^T \delta \psi + \frac{\delta S}{\delta \psi^+} \delta \psi^+ T = 0, $$

which can be explicitly written as,

$$ \partial_\mu J^\mu = 0, \quad J^\mu = \left( e \psi^+ \psi, \frac{1}{c} J \right). $$

The Poincaré symmetry consists of two parts, which are translation symmetry and Lorentz covariance. The translation symmetry means that the action and dynamical equations are invariant under the space-time translation,

$$ (x^\mu, A^\mu, \psi, \psi^+) \rightarrow (x^\mu + \epsilon^\mu, A^\mu, \psi^\prime, \psi^\prime + \epsilon^\mu). $$

Where $\epsilon^\mu$ is an arbitrary translation parameter, and the local field components admit $A^\mu(x^\mu + \epsilon^\mu) = A^\mu(x^\mu), \psi(x^\mu + \epsilon^\mu) = \psi(x^\mu), \psi^\prime(x^\mu + \epsilon^\mu) = \psi^\prime(x^\mu)$. By substituting an infinitesimal translations $\delta(x^\mu, A^\mu, \psi, \psi^+) = (\epsilon^\mu, 0, 0, 0)$ into $\delta S = 0$ and using the dynamical equations (13)-(14), we can obtain the energy-momentum conservation law as,

$$ \partial_\mu T^{\mu \nu} = 0. $$

Where the energy-momentum tensor is given as,

$$ T^{\mu \nu} = i \hbar c \bar{\psi} \gamma^\mu \partial^\nu \psi + \frac{1}{16 \pi} \mathcal{F}^2 g^{\mu \nu} - \frac{1}{4 \pi} \mathcal{F}^{\mu \rho} \partial^\nu A_\rho. $$

The Lorentz covariance means that the action and dynamical equations are invariant under the Lorentz transformation,

$$ (x^\mu, A^\mu, \psi, \psi^+) \rightarrow (A^\mu_* x^\nu, A^\nu_* A^\nu, S(\Lambda) \psi, \psi^+ S^{-1}(\Lambda)) $$

11
Where $S(\Lambda)$ admits $S(\Lambda)\gamma^\mu S^{-1}(\Lambda) = \Lambda^{-1}_\nu^\mu \gamma^\nu$, and $\Lambda^\nu_\mu$ is an arbitrary Lorentz transformation parameter. It is convenient to verify the Lorentz covariance of the canonical field theory by substituting Eq. (39) into the Lagrangian density (9) or canonical equations (23)-(32). By substituting an infinitesimal Lorentz transformation $\delta(x^\mu, A^\mu, \psi, \psi^+)$ = $(\epsilon^\mu_\nu x^\nu, \epsilon^\mu_\nu A^\nu, -\frac{i}{4} \epsilon^\mu_\eta \sigma^\eta_\xi \psi, \frac{i}{4} \psi^+ \epsilon^\mu_\eta \sigma^\eta_\xi)$ into $\delta S = 0$ and using the dynamical equations (13)-(14), we can obtain the angular momentum conservation law as,

$$\partial_\mu M^{\mu \nu \rho} = 0.$$  \hspace{1cm} (40)

Where the general angular momentum tensor is given as,

$$M^{\mu \nu \rho} = x^\nu T^{\mu \rho} - x^\rho T^{\mu \nu} + \frac{\hbar c}{2} \bar{\psi} \gamma^\mu \sigma^{\nu \rho} \psi + \frac{1}{4\pi} (A^\nu F^{\mu \rho} - A^\rho F^{\mu \nu}).$$ \hspace{1cm} (41)

Here $\epsilon^{\mu \nu} = -\epsilon^{\nu \mu}$ is an arbitrary infinitesimal Lorentz parameter, and the Lorentz generator on bispinor field is defined as $\sigma^{\mu \nu} = \frac{i}{2} [\gamma^\mu, \gamma^\nu]$ \cite{90, 91}.

### III. LATTICE CANONICAL FIELD THEORY OF THE DIRAC-MAXWELL SYSTEMS

#### A. DEC Based Discretization

The first step to construct a lattice field theory is discretization. As a differential geometry based numerical framework, DEC defines a class of complete operational rules and differential forms on a discrete differential manifold, which form a cochain complex \cite{87, 89}. To construct a semi-discrete LCFT for Dirac-Maxwell systems, the space-like submanifold of the Minkowski space-time manifold is discretized by using a rectangular lattice (other lattices are also viable). Then the scalar field $A^0 = \phi$, which is a 0-form on the space-like submanifold, naturally lives on the vertex of the lattice,

$$\phi_J (t) : \phi (t, x_i, y_j, z_k).$$ \hspace{1cm} (42)

Where the subscript $J$ indicates lattice label which traverses all lattice points, and $(x_i, y_j, z_k)$ is the coordinate of the lattice vertex. The $U(1)$ gauge and electric field 1-forms $A = A_i dx^i$
and \( Y = Y_i dx^i \) naturally live along the edges of the lattice,

\[
A/Y_{xJ}(t) = A/Y_{x}(t, x_i + \frac{\Delta x}{2}, y_j, z_k), \tag{43}
\]

\[
A/Y_{yJ}(t) = A/Y_{y}(t, x_i, y_j + \frac{\Delta y}{2}, z_k), \tag{44}
\]

\[
A/Y_{zJ}(t) = A/Y_{z}(t, x_i, y_j, z_k + \frac{\Delta z}{2}). \tag{45}
\]

In the above discretization, a half integer index indicates along which edge does the field resides, where \( \Delta x, \Delta y \) and \( \Delta z \) are lattice periods. In DEC framework, the magnetic field 2-form \( dA \) lives on the face center of the lattice. By using the Hodge dual operator \( * \), we obtain the discrete charge 3-form \(-d*Y\) and current 2-form \( d*dA \) on the volume and face centers of the dual lattice respectively. Where the coordinate of a form on dual lattice is translated by \( (\Delta x, \Delta y, \Delta z)/2 \) after the Hodge operation, which means the primary-dual lattice generated by the Hodge star is a staggered lattice. The discrete gradient \( \nabla_d \), curl \( \nabla_d \times \), and divergence \( \nabla_d \cdot \) operators in DEC framework can be defined as [85, 87],

\[
d\phi_J = (\nabla_d \phi)_J = \begin{pmatrix}
\frac{\phi_{i+1,j,k} - \phi_{i,j,k}}{\Delta x} \\
\frac{\phi_{i,j+1,k} - \phi_{i,j,k}}{\Delta y} \\
\frac{\phi_{i,j,k+1} - \phi_{i,j,k}}{\Delta z}
\end{pmatrix}, \tag{46}
\]

\[
dA_J = (\nabla_d \times A)_J = \begin{pmatrix}
\frac{A_{z_{i+1,j,k} - A_{z_{i,j,k+1}}}}{\Delta x} & \frac{A_{z_{i,j+1,k} - A_{z_{i,j,k+1}}}}{\Delta y} & \frac{A_{z_{i,j,k+1} - A_{z_{i,j,k}}}}{\Delta z} \\
\frac{A_{x_{i+1,j,k+1} - A_{x_{i,j,k+1}}}}{\Delta y} & \frac{A_{x_{i+1,j,k+1} - A_{x_{i,j,k}}}}{\Delta z} & \frac{A_{x_{i,j,k+1} - A_{x_{i,j,k}}}}{\Delta x} \\
\frac{A_{y_{i,j+1,k} - A_{y_{i,j,k+1}}}}{\Delta x} & \frac{A_{y_{i,j+1,k} - A_{y_{i,j,k}}}}{\Delta y} & \frac{A_{y_{i,j,k+1} - A_{y_{i,j,k}}}}{\Delta z}
\end{pmatrix}, \tag{47}
\]

\[
d*Y_J = (\nabla_d \cdot Y)_J = \frac{Y_{x_{i+\frac{1}{2},j,k}} - Y_{x_{i-\frac{1}{2},j,k}}}{\Delta x} + \frac{Y_{y_{i,j+\frac{1}{2},k}} - Y_{y_{i,j-\frac{1}{2},k}}}{\Delta y} + \frac{Y_{z_{i,j,k+\frac{1}{2}}} - Y_{z_{i,j,k-\frac{1}{2}}}}{\Delta z}. \tag{48}
\]

When it comes to the bispinor field, the fermion doubling is a serious problem in LGT, especially in LQCD simulations. Nielsen-Ninomiya no-go theorem states that the discretization of the Dirac equation on a regular space lattice forbids a single chirally invariant fermion flavor without breaking one or more of the following assumptions: translation invariance, locality, and Hermiticity [49]. There are several strategies to avoid this obstacle, e.g. Wilson’s momentum-dependent mass term or Kogut-Susskind staggered fermion [19, 95]. Here, in the unified DEC framework, we treat the bispinor components as different differential
forms on the space-like submanifold, which are $\psi_1, \psi_2 dx \wedge dy \wedge dz, \psi_3 dz$, and $\psi_4 dx \wedge dy$,

$$\psi_{1J}(t) : \psi_1(t, x_i, y_j, z_k),$$

$$\psi_{2J}(t) : \psi_2(t, x_i + \frac{\Delta x}{2}, y_j + \frac{\Delta y}{2}, z_k + \frac{\Delta z}{2}),$$

$$\psi_{3J}(t) : \psi_3(t, x_i, y_j, z_k + \frac{\Delta z}{2}),$$

$$\psi_{4J}(t) : \psi_4(t, x_i + \frac{\Delta x}{2}, y_j + \frac{\Delta y}{2}, z_k) .$$

Where the 4 bispinor components live on the vertex, edge, faces and volume centers of the lattice respectively. By using the Hodge dual operator, we find the dual relations $\psi_1 \overset{*}{\leftrightarrow} \psi_2$ and $\psi_3 \overset{*}{\leftrightarrow} \psi_4$, which naturally generate a staggered checkerboard-like lattice. The DEC dual relations could lead to a lattice bispinor field without fermion doubling. The DEC based discretization of the LCFT on the space-like submanifold is shown in Fig.1.

FIG. 1. DEC based discretization of the LCFT for Dirac-Maxwell systems on a rectangular lattice. (a) Discrete forms on the space-like submanifold. (b) Staggered lattice generated by the Hodge dual operator $*$, where P- indicates primary lattice and D- indicates dual lattice.

Based on the discretization of fields, we can construct a discrete Poisson bracket, which admits bilinearity, anticommutativity, product rule, and Jacobi identity. The fields can be reconstructed as,

$$A(x, t) = \sum_{J=1}^{M} A_J(t) W(x - x_J), \quad Y(x, t) = \sum_{J=1}^{M} Y_J(t) W(x - x_J),$$

$$\psi_{iR}(x, t) = \sum_{J=1}^{M} \psi_{iRJ}(t) W(x - x_J), \quad \psi_{iI}(x, t) = \sum_{J=1}^{M} \psi_{iIJ}(t) W(x - x_J).$$

Where the distribution function $W(x - x_J)$ is defined as,

$$W(x - x_J) = \begin{cases} 
1, & |x - x_J| < \frac{\Delta x}{2}, |y - y_J| < \frac{\Delta y}{2}, |z - z_J| < \frac{\Delta z}{2} \\
0, & elsewhere
\end{cases} .$$
Then, the variational derivative with respect to $A$ is

$$\frac{\delta F}{\delta A} = \sum_{j=1}^{M} \frac{\delta A_j}{\delta A} \frac{\partial F}{\partial A_j} = \sum_{j=1}^{M} \frac{1}{\Delta V} W(x - x_j) \frac{\partial F}{\partial A_j},$$

(56)

and the variational derivatives with respect to $Y_j, \psi_{iR}$ and $\psi_{iI}$ have similar expressions. Here, $\Delta V = \Delta x \wedge \Delta y \wedge \Delta z$ is the volume form on the lattice. Based on Eq. (56), the canonical Poisson bracket (19) is discretized as,

$$\{F,G\}_d = \sum_{j=1}^{M} \left[ \sum_{i=1}^{4} \left( \frac{\partial F}{\partial \psi_{iR,j}} \frac{\partial G}{\partial \psi_{iI,j}} - \frac{\partial G}{\partial \psi_{iR,j}} \frac{\partial F}{\partial \psi_{iI,j}} \right) + \sum_{i=1}^{3} \left( \frac{\partial F}{\partial A_{ij}} \frac{\partial G}{\partial Y_{ij}} - \frac{\partial G}{\partial A_{ij}} \frac{\partial F}{\partial Y_{ij}} \right) \right] \frac{1}{\Delta V}$$

$$= \sum_{j=1}^{M} \left[ \left( \frac{\partial F}{\partial \psi_{iR,j}} \right)^T \frac{\partial G}{\partial \psi_{iI,j}} - \left( \frac{\partial G}{\partial \psi_{iR,j}} \right)^T \frac{\partial F}{\partial \psi_{iI,j}} + \frac{\partial F}{\partial A_{ij}} \cdot \frac{\partial G}{\partial Y_{ij}} - \frac{\partial G}{\partial A_{ij}} \cdot \frac{\partial F}{\partial Y_{ij}} \right] \frac{1}{\Delta V}. \quad (57)

With the discrete canonical Poisson bracket (57), the functionals on the discrete cotangent bundle $T^*G_d = (\psi_{iR}, A, \psi_{iI}, Y)$ form a complete Poisson algebra. Then a semi-discrete LCFT can be generated by this discrete canonical Poisson bracket with a proper Hamiltonian functional on $T^*G_d$.

**B. Pull-back and push-forward gauge covariant derivatives**

The gauge 1-form defines the gauge connection on the $U(1)$ bundle, which enables parallel transport bispinor on the Minkowski manifold. In order to construct a gauge invariant semi-discrete LCFT, we introduce a pair of discrete gauge covariant derivatives for different bispinor components, which can be recognized as Wilson lines in the DEC framework [40]. When it comes to $D_x \psi_1, D_y \psi_1, D_z \psi_1, D_x \psi_3, D_y \psi_3$, and $D_z \psi_4$, the pull-back gauge covariant derivative $D^<_{\psi}$ is used along the relative gauge connections, e.g.,

$$\left( D^<_{\psi} \psi_1 \right)_J = \frac{1}{\Delta x} \left( \psi_{1i+1,j,k} e^{-i \frac{e}{\hbar c} A_{xi+1,j,k} \Delta x} - \psi_{1i,j,k} \right)$$

$$= \frac{1}{\sqrt{2i \Delta x}} \left\{ \psi_{1Ri+1,j,k} \cos \left( \frac{e}{\hbar c} A_{xi+1,j,k} \Delta x \right) + \psi_{1Hi+1,j,k} \sin \left( \frac{e}{\hbar c} A_{xi+1,j,k} \Delta x \right) - \psi_{1Ri,j,k} \right.$$

$$+ \left. i \left[ \psi_{1Hi+1,j,k} \cos \left( \frac{e}{\hbar c} A_{xi+1,j,k} \Delta x \right) - \psi_{1Ri+1,j,k} \sin \left( \frac{e}{\hbar c} A_{xi+1,j,k} \Delta x \right) - \psi_{1Hi,j,k} \right] \right\} (58)$$

The other $D^<_{\psi}$ components can be given in a similar form.

When it comes to $D_x \psi_2, D_y \psi_2, D_z \psi_2, D_x \psi_4, D_y \psi_4$, and $D_z \psi_3$, the push-forward gauge
covariant derivative $D^>$ is used along the relative gauge connections, e.g.,

$$(D^>_z \psi_3)_J = \frac{1}{\Delta z} \left( \psi_{3i,j,k+\frac{1}{2}} - \psi_{3i,j,k-\frac{1}{2}} e^{\frac{ie}{\hbar c} A_{zi,j,k-\frac{1}{2}} \Delta z} \right)$$

$$= \frac{1}{\sqrt{2\hbar \Delta z}} \left\{ \psi_{3Ri,j,k+\frac{1}{2}} - \psi_{3Ri,j,k-\frac{1}{2}} \cos \left( \frac{e}{\hbar c} A_{zi,j,k-\frac{1}{2}} \Delta z \right) + \psi_{3Ri,j,k-\frac{1}{2}} \sin \left( \frac{e}{\hbar c} A_{zi,j,k-\frac{1}{2}} \Delta z \right) + i \left[ \psi_{3Ri,j,k+\frac{1}{2}} - \psi_{3Ri,j,k-\frac{1}{2}} \cos \left( \frac{e}{\hbar c} A_{zi,j,k-\frac{1}{2}} \Delta z \right) - \psi_{3Ri,j,k-\frac{1}{2}} \sin \left( \frac{e}{\hbar c} A_{zi,j,k-\frac{1}{2}} \Delta z \right) \right] \} \right\}$$

The other $D^<$ components can be given in a similar form.

By using $\nabla_d$ operator, the semi-discrete gauge transformation can be defined as,

$$\phi'_J = \phi_J - \frac{1}{c} \dot{\theta}_J, \quad (60)$$

$$A'_J = A_J + (\nabla_d \theta)_J, \quad (61)$$

$$\psi'_J = \psi_J e^{i \frac{e}{\hbar c} \theta_J}. \quad (62)$$

Where $\theta_J$ is an arbitrary discrete 0-form.

By substituting Eqs. (60)-(62) into Eqs. (58)-(59), we obtain the gauge property of pullback and push-forward gauge covariant derivatives,

$$\left(D^<_x \psi_1\right)_J e^{i \frac{e}{\hbar c} \theta_J} A_{x,J} + (\nabla_d \theta)_{x,J} \left(D^<_x \psi_1\right)_J e^{i \frac{e}{\hbar c} \theta_J}, \quad (63)$$

$$\left(D^>_z \psi_3\right)_J e^{i \frac{e}{\hbar c} \theta_J} A_{z,J} + (\nabla_d \theta)_{z,J} \left(D^>_z \psi_3\right)_J e^{i \frac{e}{\hbar c} \theta_J}. \quad (64)$$

It shows that after a gauge transformation, the pull-back and push-forward gauge covariant derivatives get an unified phase, which ensures the semi-discrete Lagrangian density of the bispinor is gauge invariant.

The semi-discrete Lagrangian density of the $U(1)$ gauge field is also gauge invariant in the DEC framework, which can be directly verified. As a result, the semi-discrete action functional admits gauge symmetry.

C. Semi-discrete canonical field theory

With the DEC and discrete gauge covariant derivatives, the Hamiltonian functional (17) is discreted as,

$$H_d = H_d^{(1)} + H_d^{(2)} + H_d^{(3)}. \quad (65)$$
Where the superscript means 1- bispinor momentum, 2- bispinor mass-energy, and 3- $U(1)$ gauge field respectively. The discrete Hamiltonian functionals are given as,

$$
H_d^{(1)} = -i\hbar c \sum_{j=1}^{\mathcal{N}} \begin{pmatrix} \psi_{1J} \\ \psi_{2J} \\ \psi_{3J} \\ \psi_{4J} \end{pmatrix}^T \begin{pmatrix} 0 & 0 & D_z^> & D_x^+ - iD_y^< \\ 0 & 0 & D_x^+ + iD_y^< & -D_z^< \\ D_z^< & D_x^+ - iD_y^> & 0 & 0 \\ D_x^+ + iD_y^< & -D_z^> & 0 & 0 \end{pmatrix} \begin{pmatrix} \psi_{1J} \\ \psi_{2J} \\ \psi_{3J} \\ \psi_{4J} \end{pmatrix} \Delta \mathcal{V},
$$

$$
H_d^{(2)} = \sum_{j=1}^{\mathcal{N}} \frac{\Delta V}{2\hbar} \left[ (e\phi_j + mc^2) \left( \psi_{1RJ}^2 + \psi_{2RJ}^2 + \psi_{1IJ}^2 + \psi_{2IJ}^2 \right) + (e\phi_j - mc^2) \left( \psi_{3RJ}^2 + \psi_{4RJ}^2 + \psi_{3IJ}^2 + \psi_{4IJ}^2 \right) \right],
$$

$$
H_d^{(3)} = \sum_{j=1}^{\mathcal{N}} \frac{1}{8\pi} \left[ 16\pi^2 c^2 \mathbf{Y}^2_j + (\nabla_d \times \mathbf{A})_j^2 - 8\pi c \mathbf{Y}_j \cdot (\nabla_d \phi)_j \right] \Delta V.
$$

Eqs. (66)-(67) show that the $\gamma^\mu$ matrices and relevant Clifford algebra are preserved in the semi-discrete LCFT.

By substituting the discrete Hamiltonian functional (65) into the discrete Poisson bracket (57), we obtain the canonical equations of the semi-discrete LCFT for Dirac-Maxwell systems. Here, we introduce the Hamiltonian splitting method and generate three linear canonical subsystems [83].

The subsystem generated by $H_d^{(1)}$ is given as,

$$
\psi_{1RJ} = \{ \psi_{1RJ}, H_d^{(1)} \} = \frac{c}{\Delta x} \left( \psi_{4RJ-1} \cos_j \phi_{j-1} - \psi_{4IJ-1} \sin_j \phi_{j-1} - \psi_{4RJ} \right) + \frac{c}{\Delta y} \left( \psi_{4IJ-1} \cos_j \phi_{j-1} + \psi_{4RJ-1} \sin_j \phi_{j-1} - \psi_{4IJ} \right) + \frac{c}{\Delta z} \left( \psi_{4RJ-1} \cos_j \phi_{j-1} - \psi_{4IJ-1} \sin_j \phi_{j-1} - \psi_{4RJ} \right),
$$

$$
\psi_{2RJ} = \{ \psi_{2RJ}, H_d^{(1)} \} = \frac{c}{\Delta x} \left( \psi_{3RJ} - \psi_{3RJ+1} \cos_j \phi_{j+1} - \psi_{3IJ+1} \sin_j \phi_{j+1} \right) + \frac{c}{\Delta y} \left( \psi_{3IJ+1} \cos_j \phi_{j+1} - \psi_{3RJ+1} \sin_j \phi_{j+1} - \psi_{3IJ} \right) + \frac{c}{\Delta z} \left( \psi_{4RJ+1} \cos_j \phi_{j+1} + \psi_{4IJ+1} \sin_j \phi_{j+1} - \psi_{4RJ} \right),
$$
\[
\dot{\psi}_{3RJ} = \left\{ \psi_{3RJ}, H_d^{(1)} \right\} = \frac{c}{\Delta x} \left( \psi_{2RJ-1} \cos x_{j-1} - \psi_{2IJ-1} \sin x_{j-1} - \psi_{2RJ} \right) + \frac{c}{\Delta y} \left( \psi_{2IJ-1} \cos y_{j-1} + \psi_{2RJ-1} \sin y_{j-1} - \psi_{2IJ} \right) + \frac{c}{\Delta z} \left( \psi_{1RJ} - \psi_{1RJ+1} \cos \tilde{\gamma} - \psi_{1IJ+1} \sin \tilde{\gamma} \right),
\]

\[
\dot{\psi}_{4RJ} = \left\{ \psi_{4RJ}, H_d^{(1)} \right\} = \frac{c}{\Delta x} \left( \psi_{1RJ} - \psi_{1RJ+1} \cos \tilde{x} - \psi_{1IJ+1} \sin \tilde{x} \right) + \frac{c}{\Delta y} \left( \psi_{1IJ+1} \cos \tilde{y} - \psi_{1RJ+1} \sin \tilde{y} - \psi_{1IJ} \right) + \frac{c}{\Delta z} \left( \psi_{2RJ} - \psi_{2RJ-1} \cos \tilde{x}_{j-1} + \psi_{2IJ-1} \sin \tilde{x}_{j-1} \right),
\]

\[
\dot{\psi}_{1IJ} = \left\{ \psi_{1IJ}, H_d^{(1)} \right\} = \frac{c}{\Delta x} \left( \psi_{4IJ-1} \cos \tilde{x}_{j-1} + \psi_{4RJ-1} \sin \tilde{x}_{j-1} - \psi_{4IJ} \right) + \frac{c}{\Delta y} \left( \psi_{4RJ-1} \cos \tilde{y}_{j-1} + \psi_{4IJ-1} \sin \tilde{y}_{j-1} \right) + \frac{c}{\Delta z} \left( \psi_{3IJ-1} \cos \tilde{z}_{j-1} + \psi_{3RJ-1} \sin \tilde{z}_{j-1} - \psi_{3IJ} \right),
\]

\[
\dot{\psi}_{2IJ} = \left\{ \psi_{2IJ}, H_d^{(1)} \right\} = \frac{c}{\Delta x} \left( \psi_{3IJ} - \psi_{3IJ+1} \cos \tilde{x} + \psi_{3RJ+1} \sin \tilde{x} \right) + \frac{c}{\Delta y} \left( \psi_{3RJ+1} \cos \tilde{y} - \psi_{3IJ+1} \sin \tilde{y} \right) + \frac{c}{\Delta z} \left( \psi_{4IJ+1} \cos \tilde{z} - \psi_{4RJ+1} \sin \tilde{z} - \psi_{4IJ} \right),
\]

\[
\dot{\psi}_{3IJ} = \left\{ \psi_{3IJ}, H_d^{(1)} \right\} = \frac{c}{\Delta x} \left( \psi_{2IJ-1} \cos \tilde{x}_{j-1} + \psi_{2RJ-1} \sin \tilde{x}_{j-1} - \psi_{2IJ} \right) + \frac{c}{\Delta y} \left( \psi_{2RJ-1} \cos \tilde{y}_{j-1} + \psi_{2IJ-1} \sin \tilde{y}_{j-1} \right) + \frac{c}{\Delta z} \left( \psi_{1IJ} - \psi_{1IJ+1} \cos \tilde{z} + \psi_{1RJ+1} \sin \tilde{z} \right),
\]

\[
\dot{\psi}_{4IJ} = \left\{ \psi_{4IJ}, H_d^{(1)} \right\} = \frac{c}{\Delta x} \left( \psi_{1IJ} - \psi_{1IJ+1} \cos \tilde{z} + \psi_{1RJ+1} \sin \tilde{z} \right) + \frac{c}{\Delta y} \left( \psi_{1RJ+1} \cos \tilde{y} - \psi_{1IJ+1} \sin \tilde{y} \right) + \frac{c}{\Delta z} \left( \psi_{2IJ} - \psi_{2IJ-1} \cos \tilde{z}_{j-1} - \psi_{2RJ-1} \sin \tilde{z}_{j-1} \right),
\]

\[
\dot{A}_J = \left\{ A_J, H_d^{(1)} \right\} = 0,
\]

\[
Y_{xJ} = \left\{ Y_{xJ}, H_d^{(1)} \right\} = \frac{c}{\hbar} \left[ \left( \psi_{1RJ+1} \psi_{4RJ} + \psi_{1IJ+1} \psi_{4IJ} + \psi_{2RJ} \psi_{3RJ+1} + \psi_{2IJ} \psi_{3IJ+1} \right) \cos \tilde{x} + \left( \psi_{1IJ+1} \psi_{4RJ} - \psi_{1RJ+1} \psi_{4IJ} - \psi_{2IJ} \psi_{3RJ+1} + \psi_{2RJ} \psi_{3IJ+1} \right) \sin \tilde{x} \right],
\]

18
\[ Y_y^J = \left\{ Y_y^J, H_d^{(1)} \right\} \]
\[ = \frac{e}{\hbar} \left[ (\psi_{1RJ+1}\psi_{4IJ} - \psi_{1IJ+1}\psi_{4RJ} - \psi_{2RJ}\psi_{3IJ+1} + \psi_{2IJ}\psi_{3RJ+1}) \cos^y_J \right. \]
\[ + (\psi_{1RJ+1}\psi_{4RJ} + \psi_{1IJ+1}\psi_{4IJ} + \psi_{2RJ}\psi_{3RJ+1} + \psi_{2IJ}\psi_{3IJ+1}) \sin^y_J \left. \right] \]  
(79)

\[ Y_z^J = \left\{ Y_z^J, H_d^{(1)} \right\} \]
\[ = \frac{e}{\hbar} \left[ (\psi_{1RJ+1}\psi_{3RJ} + \psi_{1IJ+1}\psi_{3IJ} - \psi_{2RJ}\psi_{4RJ+1} - \psi_{2IJ}\psi_{4IJ+1}) \cos^z_J \right. \]
\[ + (\psi_{1IJ+1}\psi_{3RJ} - \psi_{1RJ+1}\psi_{3IJ} - \psi_{2RJ}\psi_{4IJ+1} + \psi_{2IJ}\psi_{4RJ+1}) \sin^z_J \right. \]  
(80)

Where the Wilson line components \( \cos / \sin^x_J \) are defined as,
\[ \cos / \sin^x_J \triangleq \cos / \sin \left( \frac{e}{\hbar c} A_{x_i + \frac{1}{2} j,k} \Delta x \right) \]  
(81)

\[ \cos / \sin^y_J \triangleq \cos / \sin \left( \frac{e}{\hbar c} A_{y_i + \frac{1}{2} j,k} \Delta y \right) \]  
(82)

\[ \cos / \sin^z_J \triangleq \cos / \sin \left( \frac{e}{\hbar c} A_{z_i,j,k+\frac{1}{2}} \Delta z \right) \]  
(83)

In these equations, the translations of lattice index \( J \pm 1 \) along the relevant gauge connections.

The subsystem generated by \( H_d^{(2)} \) is given as,
\[ \dot{\psi}_{1RJ} = \left\{ \psi_{1RJ}, H_d^{(2)} \right\} = \frac{1}{\hbar} \left( e\phi_J + mc^2 \right) \psi_{1IJ}, \]  
(84)

\[ \dot{\psi}_{2RJ} = \left\{ \psi_{2RJ}, H_d^{(2)} \right\} = \frac{1}{\hbar} \left( e\phi_J + mc^2 \right) \psi_{2IJ}, \]  
(85)

\[ \dot{\psi}_{3RJ} = \left\{ \psi_{3RJ}, H_d^{(2)} \right\} = \frac{1}{\hbar} \left( e\phi_J - mc^2 \right) \psi_{3IJ}, \]  
(86)

\[ \dot{\psi}_{4RJ} = \left\{ \psi_{4RJ}, H_d^{(2)} \right\} = \frac{1}{\hbar} \left( e\phi_J - mc^2 \right) \psi_{4IJ}, \]  
(87)

\[ \dot{\psi}_{1IJ} = \left\{ \psi_{1IJ}, H_d^{(2)} \right\} = -\frac{1}{\hbar} \left( e\phi_J + mc^2 \right) \psi_{1RJ}, \]  
(88)

\[ \dot{\psi}_{2IJ} = \left\{ \psi_{2IJ}, H_d^{(2)} \right\} = -\frac{1}{\hbar} \left( e\phi_J + mc^2 \right) \psi_{2RJ}, \]  
(89)

\[ \dot{\psi}_{3IJ} = \left\{ \psi_{3IJ}, H_d^{(2)} \right\} = -\frac{1}{\hbar} \left( e\phi_J - mc^2 \right) \psi_{3RJ}, \]  
(90)

\[ \dot{\psi}_{4IJ} = \left\{ \psi_{4IJ}, H_d^{(2)} \right\} = -\frac{1}{\hbar} \left( e\phi_J - mc^2 \right) \psi_{4RJ}, \]  
(91)
\dot{A}_J = \{ A_J, H_d^{(2)} \} = 0, \quad (92)

\dot{Y}_J = \{ Y_J, H_d^{(2)} \} = 0. \quad (93)

The second subsystem can be solved exactly when \( \phi_J(t) \) is given explicitly.

The subsystem generated by \( H_d^{(3)} \) is given as,

\[ \dot{\psi}_{RJ} = \left\{ \psi_{RJ}, H_d^{(3)} \right\} = 0, \quad (94) \]

\[ \dot{\psi}_{IJ} = \left\{ \psi_{IJ}, H_d^{(3)} \right\} = 0, \quad (95) \]

\[ \dot{A}_J = \{ A_J, H_d^{(2)} \} = 4\pi c^2 Y_J - c (\nabla d \phi)_J, \quad (96) \]

\[ \dot{Y}_J = \{ Y_J, H_d^{(2)} \} = -\frac{1}{4\pi} \left( \nabla_d \times \nabla_d \times A \right)_J. \quad (97) \]

Where the discrete operator \( \nabla_d^T \times \nabla_d \times \) is defined as,

\[ \left( \nabla_d^T \times \nabla_d \times A \right)_J \triangleq \frac{1}{2} \frac{\partial}{\partial A_J} \left[ \sum_{K=1}^{M} (\nabla_d \times A)_K^2 \right]. \quad (98) \]

Because the semi-discrete action functional admits \( U(1) \) gauge symmetry, the semi-discrete LCFT for Dirac-Maxwell systems is gauge invariant. Because there are no explicit lattice coordinates in the semi-discrete action functional, it admits translation symmetry, then the semi-discrete LCFT for Dirac-Maxwell systems is translation invariant. Because the \( \gamma^\mu \) matrices and relevant Clifford algebra are preserved, then the semi-discrete LCFT for Dirac-Maxwell systems is Lorentz covariant. We should emphasize that when the DEC lattice is fixed, the Lorentz boosts are forbidden, and there are only parity, time-reversal, and discrete rotations with angles \((l\pi/2, m\pi/2, n\pi/2)\) exist in the Lorentz group \( SO(3,1) \).

IV. STRUCTURE-PRESERVING GEOMETRIC ALGORITHMS

A. Gauge and Poincaré invariant canonical symplectic algorithms

Based on the Hamiltonian splitting method, the three linear canonical subsystems can be solved independently. The solution maps of the subsystems will be combined in various ways to give desired structure-preserving geometric algorithms for the semi-discrete LCFT.
For the subsystem generated by $H^{(1)}_d$, the canonical equations (69)-(80) can be rewritten as,

\[
\begin{pmatrix}
\dot{\psi}_{iR} \\
\dot{\psi}_{iI}
\end{pmatrix} = \Xi(A) \begin{pmatrix}
\psi_{iR} \\
\psi_{iI}
\end{pmatrix},
\]  

(99)

\[
\begin{pmatrix}
\dot{A} \\
\dot{Y}
\end{pmatrix} = \begin{pmatrix}
0 \\
\mathcal{J}(\psi_{iR}, \psi_{iI}, A)
\end{pmatrix}.
\]  

(100)

Where $\Xi(A)$ is an skew-symmetric matrix, which is also an infinitesimal generator of the symplectic group. To preserve the unitary property of the bispinor field, we adopt the symplectic mid-point method for this subsystem, and the one step map $M_D(\Delta t) : (\psi_{iR}, A, \psi_{iI}, Y)^n \mapsto (\psi_{iR}, A, \psi_{iI}, Y)^{n+1}$ can be given as,

\[
\begin{pmatrix}
\psi_{iR} \\
\psi_{iI}
\end{pmatrix}^{n+1} = C_{ay} \left[ \Xi(A^n) \frac{\Delta t}{2} \right] \begin{pmatrix}
\psi_{iR} \\
\psi_{iI}
\end{pmatrix}^n,
\]  

(101)

\[A^{n+1} = A^n,\]  

(102)

\[Y^{n+1} = Y^n + \Delta t \mathcal{J} \left( \frac{\psi_{iR}^n + \psi_{iR}^{n+1}}{2}, \frac{\psi_{iI}^n + \psi_{iI}^{n+1}}{2}, A^n \right).\]  

(103)

Eq. (101) is a linear algebraic equation whose solution can be written as,

\[
C_{ay} \left[ \Xi(A^n) \frac{\Delta t}{2} \right] = \left[ 1 - \Xi(A^n) \frac{\Delta t}{2} \right]^{-1} \left[ 1 + \Xi(A^n) \frac{\Delta t}{2} \right].
\]  

(105)

Where $C_{ay}(S)$ denotes the Cayley transformation. It is well-known that $C_{ay}(S)$ is a symplectic rotation transformation when $S$ in the Lie algebra of the symplectic rotation group [69]. As a result, the one step solution map $M_D(\Delta t) : (\psi_{iR}, A, \psi_{iI}, Y)^n \mapsto (\psi_{iR}, A, \psi_{iI}, Y)^{n+1}$ is symplectic and unitary for bispinor field. Once $\psi^{n+1}$ is known, $Y^{n+1}$ can be calculated explicitly via Eq. (103). Thus, $M_D(\Delta t) : (\psi_{iR}, A, \psi_{iI}, Y)^n \mapsto (\psi_{iR}, A, \psi_{iI}, Y)^{n+1}$ is a second order symplectic scheme, which also preserves the unitariness of the bispinor field.
For the subsystem generated by $H_d^{(2)}$, the canonical equations [84]-[93] can be solved exactly when $\phi_j(t)$ is given explicitly. Because the LCFT is gauge invariant, we can get an explicit $\phi_j(t)$ by adopting some gauge conditions, such as the temporal gauge $\phi = 0$. Here, the one step solution map $M_M(\Delta t) : (\psi_{iR}, A, \psi_{iI}, Y)^n \mapsto (\psi_{iR}, A, \Psi_{iI}, Y)^{n+1}$ can be given as,

$$
\psi_{1RJ}^{n+1} = \psi_{1RJ}^n \cos \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^+ (\tau) \, d\tau \right) + \psi_{1IJ}^n \sin \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^+ (\tau) \, d\tau \right), \quad (106)
$$

$$
\psi_{2RJ}^{n+1} = \psi_{2RJ}^n \cos \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^+ (\tau) \, d\tau \right) + \psi_{2IJ}^n \sin \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^+ (\tau) \, d\tau \right), \quad (107)
$$

$$
\psi_{3RJ}^{n+1} = \psi_{3RJ}^n \cos \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^- (\tau) \, d\tau \right) + \psi_{3IJ}^n \sin \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^- (\tau) \, d\tau \right), \quad (108)
$$

$$
\psi_{4RJ}^{n+1} = \psi_{4RJ}^n \cos \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^- (\tau) \, d\tau \right) + \psi_{4IJ}^n \sin \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^- (\tau) \, d\tau \right), \quad (109)
$$

$$
\psi_{1IJ}^{n+1} = \psi_{1IJ}^n \cos \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^+ (\tau) \, d\tau \right) - \psi_{1RJ}^n \sin \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^+ (\tau) \, d\tau \right), \quad (110)
$$

$$
\psi_{2IJ}^{n+1} = \psi_{2IJ}^n \cos \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^+ (\tau) \, d\tau \right) - \psi_{2RJ}^n \sin \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^+ (\tau) \, d\tau \right), \quad (111)
$$

$$
\psi_{3IJ}^{n+1} = \psi_{3IJ}^n \cos \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^- (\tau) \, d\tau \right) - \psi_{3RJ}^n \sin \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^- (\tau) \, d\tau \right), \quad (112)
$$

$$
\psi_{4IJ}^{n+1} = \psi_{4IJ}^n \cos \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^- (\tau) \, d\tau \right) - \psi_{4RJ}^n \sin \left( \int_{n\Delta t}^{(n+1)\Delta t} \omega_j^- (\tau) \, d\tau \right), \quad (113)
$$

$$
\begin{pmatrix}
\mathbf{A} \\
\mathbf{Y}
\end{pmatrix}^{n+1} = \begin{pmatrix}
\mathbf{A} \\
\mathbf{Y}
\end{pmatrix}^n. \quad (114)
$$

Where $\omega_j^\pm (\tau) = \left[e\phi_j(\tau) \pm mc^2\right]/\hbar$ are eigen-frequencies of the fermion and anti-fermion. Because Eqs. (106)-(114) are rigorous solutions of the second subsystem in one step, the
map $M_M(\Delta t) : (\psi_{iR}, A, \psi_{iI}, Y)^n \mapsto (\psi_{iR}, A, \Psi_{iI}, Y)^{n+1}$ is a symplectic scheme, which also preserves the unitariness of the bispinor field.

For the subsystem generated by $H_d^{(3)}$, the canonical equations (94)-(97) can be rewritten as,

$$
\begin{pmatrix}
\dot{\psi}_{iR} \\
\dot{\psi}_{iI}
\end{pmatrix} = 0, 
$$

$$
\begin{pmatrix}
\dot{A} \\
\dot{Y}
\end{pmatrix} = Q \begin{pmatrix}
A \\
Y
\end{pmatrix} .
$$

Where $Q$ is a constant matrix which belongs to the Lie algebra of the symplectic group. We also use the second order symplectic mid-point rule for this subsystem, and the one step map $M_G(\Delta t) : (\psi_{iR}, A, \psi_{iI}, Y)^n \mapsto (\psi_{iR}, A, \Psi_{iI}, Y)^{n+1}$ can be given as,

$$
\begin{pmatrix}
\psi_{iR}^{n+1} \\
\psi_{iI}^{n+1}
\end{pmatrix} = \begin{pmatrix}
\psi_{iR}^n \\
\psi_{iI}^n
\end{pmatrix} ,
$$

$$
\begin{pmatrix}
A^{n+1} \\
Y^{n+1}
\end{pmatrix} = \text{Cay} \left( Q \frac{\Delta t}{2} \right) \begin{pmatrix}
A^n \\
Y^n
\end{pmatrix} .
$$

$M_G(\Delta t) : (\psi_{iR}, A, \psi_{iI}, Y)^n \mapsto (\psi_{iR}, A, \Psi_{iI}, Y)^{n+1}$ is symplectic. Because the bispinor field does not evolve in the third subsystem, the scheme is unitary.

Because the one step solution maps $M_D(\Delta t)$ and $M_G(\Delta t)$ generated by the Cayley transformation are time-symmetric symplectic schemes [69], they do not break the $U(1)$ gauge and Poincaré symmetries admitted by the semi-discrete LCFT for the Dirac-Maxwell systems.

Obviously, the solution map $M_M(\Delta t)$ does not break the symmetries, for it is locally rigorous. Given $M_D(\Delta t)$, $M_M(\Delta t)$, and $M_G(\Delta t)$ for $H_d^{(1)}$, $H_d^{(2)}$, and $H_d^{(3)}$ subsystems respectively, a first order algorithm for the LCFT can be obtained by composition,

$$
M(\Delta t) = M_G(\Delta t) \circ M_D(\Delta t) \circ M_M(\Delta t) .
$$

A second order symplectic symmetric method can be constructed by the following symmetric composition,

$$
M^2(\Delta t) = M_M \left( \frac{\Delta t}{2} \right) \circ M_D \left( \frac{\Delta t}{2} \right) \circ M_G(\Delta t) \circ M_D \left( \frac{\Delta t}{2} \right) \circ M_M \left( \frac{\Delta t}{2} \right) .
$$
From a $2l$-th order symplectic symmetric method $M^{2l}(\Delta t)$, a $2(l + 1)$-th order symplectic symmetric method can be constructed as [69],

$$M^{2(l+1)}(\Delta t) = M^{2l}(a_l \Delta t) \circ M^{2l}(b_l \Delta t) \circ M^{2l}(a_l \Delta t),$$  \hspace{1cm} (121)

$$a_l = \left(2 - 2^{1/(2l+1)}\right)^{-1}, \quad b_l = 1 - 2a_l.$$  \hspace{1cm} (122)

Obviously, the high order algorithms for the LCFT are symplectic and unitary structure-preserving, gauge and Poincaré invariant.

**B. Fermion doubling free and numerical stability**

Fermion doubling problem is induced by a bad numerical dispersion of the free Dirac equation, which introduces pseudo cones in the Brillouin zone (BZ) of the lattice [53, 60]. As a result, pseudo-fermion modes could be excited on the lattice and a fermion could have a velocity faster than $c$. We can prove that this problem does not exist in this work. The plane wave modes of the bispinor field on the DEC lattice can be given as,

$$\psi^n_j = \frac{1}{2\hbar} \begin{bmatrix} \tilde{\psi}_{1R} + i\tilde{\psi}_{1I} \\ \tilde{\psi}_{2R} + i\tilde{\psi}_{2I} e^{i(k_x \Delta x^2 + k_y \Delta y^2 + k_z \Delta z^2)} \\ \tilde{\psi}_{3R} + i\tilde{\psi}_{3I} e^{ik_z \Delta z} \\ \tilde{\psi}_{4R} + i\tilde{\psi}_{4I} e^{ik_x \Delta x + k_y \Delta y} \end{bmatrix} e^{i(k_x x_1+k_y y_1+k_z z_1-\omega t_l)}.$$  \hspace{1cm} (123)

Where the superscript $\sim$ means amplitude. By substituting Eq. (123) into the $H^{(1)}_d$ subsystem, and setting the $U(1)$ gauge field $A^\mu = 0$, we obtain the numerical dispersion of a mass free fermion as,

$$\tan^2 \left( \frac{\omega \Delta t}{\Delta \Delta t^2} \right) = c^2 \left[ \frac{\sin^2 \left( \frac{k_x \Delta x^2}{2} \right)}{\Delta \Delta x^2} + \frac{\sin^2 \left( \frac{k_y \Delta y^2}{2} \right)}{\Delta \Delta y^2} + \frac{\sin^2 \left( \frac{k_z \Delta z^2}{2} \right)}{\Delta \Delta z^2} \right] .$$  \hspace{1cm} (124)

Once $(\Delta t, \Delta x) \rightarrow (0, 0)$, the continuum limit of Eq. (124) can be obtained as,

$$\omega = \pm c \sqrt{k_x^2 + k_y^2 + k_z^2},$$  \hspace{1cm} (125)

which is the rigorous dispersion of mass free fermions. With the de Broglie relation $E = \hbar \omega$, we obtain the energy spectrum,

$$E = \pm \frac{2\hbar}{\Delta t} \arctan \left[ \frac{c \Delta t}{2} \sqrt{\frac{\sin^2 \left( \frac{k_x \Delta x^2}{2} \right)}{\Delta \Delta x^2} + \frac{\sin^2 \left( \frac{k_y \Delta y^2}{2} \right)}{\Delta \Delta y^2} + \frac{\sin^2 \left( \frac{k_z \Delta z^2}{2} \right)}{\Delta \Delta z^2}} \right] .$$  \hspace{1cm} (126)
Where the momentum $k$ is restricted in the lattice BZ $k \in [-\pi/\Delta x, \pi/\Delta x]$. Eq. (126) shows that there is only one cone centered at $k = 0$ in the lattice BZ, and the Kramers and time-reversal symmetries are preserved. As a result, the LCFT for Dirac-Maxwell systems constructed in this work is fermion doubling free.

The numerical dispersion (124) shows that the energy $\hbar \omega$ is always real for arbitrary lattice periods $(\Delta t, \Delta x)$, which means that the solution map $M_D(\Delta t)$ of $H_d^{(1)}$ subsystem is locally unconditional stable. The $H_d^{(2)}$ subsystem is solved exactly, which means the solution map $M_M(\Delta t)$ is unconditional stable. The solution map $M_C(\Delta t)$ of $H_d^{(3)}$ subsystem equals to the Crank-Nicolson FDTD method for Maxwell’s equations, which is a well-known unconditional stable CED scheme. As a result, the high order solution map $M(\Delta t)$ for the LCFT is locally unconditional stable.

To implement the algorithms, Jacobian inversions are needed, as the Cayley transformation brings several linear algebraic equations. The Krylov subspace theory provides us with many efficient linear solvers, such as the generalized minimum residual (GMRES) method, the incomplete Cholesky conjugate gradient (ICCG) method, and the biconjugate gradient stabilized (BICGSTAB) method, which can be used to solve the large sparse matrix equation. Based on these efficient linear solvers, the algorithms can be conveniently implemented via standard parallel strategies.

\section*{C. Field quantization}

In classical statistic regime, the quantization of Dirac field can be simulated via a statistically quantization-equivalent ensemble, which can reconstruct pairs of anticommuting creation and annihilation operators in a statistic sense. The low-cost fermions strategy is such an ensemble model widely used in real-time LGT simulations [29, 30]. Along this approach, we introduce a unified ensemble model of vacuum and plasmas into the LCFT to realize real-time LCFT simulations for abundant SFQED and RQP phenomena. Based on the standard canonical quantization procedure, the Dirac bispinor field can be quantized as [90, 91, 96],

\begin{equation}
\psi (x, t) = \frac{1}{(2\pi \hbar)^3} \int_{-\infty}^{\infty} \sum_s \left[ a^s u_s (p) e^{-i \xi t / \hbar} + b^{s+} v_s (-p) e^{i \xi t / \hbar} \right] e^{i p \cdot x / \hbar} \, d^3p, \quad (127)
\end{equation}
\[
\tilde{\psi}(\mathbf{x}, t) = \frac{1}{(2\pi\hbar)^3} \int_{-\infty}^{\infty} \sum_{s} \left[ b_{p}^{s} \bar{u}_{s}(\mathbf{p}) e^{-i \frac{E_{s} t}{\hbar}} + a_{-p}^{s} \bar{u}_{s}(\mathbf{-p}) e^{i \frac{E_{s} t}{\hbar}} \right] e^{i \frac{p \cdot \mathbf{x}}{\hbar}} d^{3}p. \tag{128}
\]

Where \(\{a_{p}^{s}, a_{p}^{s+}\} = (2\pi\hbar)^{3}\delta(\mathbf{p} - \mathbf{p'})\delta_{s,s'}\) and \(\{b_{p}^{s}, b_{p}^{s+}\} = (2\pi\hbar)^{3}\delta(\mathbf{p} - \mathbf{p'})\delta_{s,s'}\) are creation and annihilation operators for fermions and antifermions respectively, with spin index \(s = \pm \frac{1}{2}\). \(u_{s}(\mathbf{p})\) and \(v_{s}(\mathbf{p})\) are relevant eigen spinors of free particles, which can be normalized as,

\[
u_{\frac{1}{2}}^{s}(\mathbf{p}) = \sqrt{\frac{E + mc^{2}}{2E}} \left( \frac{U_{\uparrow}}{E + mc^{2}U_{\uparrow}} \right) , \quad u_{-\frac{1}{2}}^{s}(\mathbf{p}) = \sqrt{\frac{E + mc^{2}}{2E}} \left( \frac{U_{\downarrow}}{-E + mc^{2}U_{\downarrow}} \right) , \tag{129}\]

\[
u_{\frac{1}{2}}^{s}(\mathbf{p}) = \sqrt{\frac{E + mc^{2}}{2E}} \left( \frac{E + mc^{2}}{U_{\uparrow}} \right) , \quad v_{-\frac{1}{2}}^{s}(\mathbf{p}) = \sqrt{\frac{E + mc^{2}}{2E}} \left( \frac{-E + mc^{2}}{U_{\downarrow}} \right) . \tag{130}\]

Where \(U^{*}\) are normalized Pauli spinors \(U^{*}U^{s'} = \delta_{s,s'}\). \(E\) is the positive definite energy norm of an on shell fermion. Then the orthogonality relations \(u_{s}^{+}(\mathbf{p})u_{s'}^{s}(\mathbf{p}) = v_{s}^{+}(\mathbf{p})v_{s'}^{s}(\mathbf{p}) = \delta_{s,s'}\) and \(u_{s}^{+}(\mathbf{p})v_{s'}^{s}(\mathbf{-p}) = 0\) can be obtained directly.

To achieve the Fermi-Dirac statistics via a classical Dirac field ensemble, we replace the creation and annihilation operators with a class of stochastic variables and reconstruct a pair of stochastic Dirac spinors as,

\[
\psi_{M}(\mathbf{x}, 0) = \frac{1}{(2\pi\hbar)^{3}} \int_{-\infty}^{\infty} \sum_{s} \frac{1}{\sqrt{2}} \left[ \xi^{s}(\mathbf{p}) u_{s}(\mathbf{p}) + \eta^{s}(\mathbf{p}) v_{s}(\mathbf{-p}) \right] e^{i \frac{p \cdot \mathbf{x}}{\hbar}} d^{3}p , \tag{131}\]

\[
\psi_{F}(\mathbf{x}, 0) = \frac{1}{(2\pi\hbar)^{3}} \int_{-\infty}^{\infty} \sum_{s} \frac{1}{\sqrt{2}} \left[ \xi^{s}(\mathbf{p}) u_{s}(\mathbf{p}) - \eta^{s}(\mathbf{p}) v_{s}(\mathbf{-p}) \right] e^{i \frac{p \cdot \mathbf{x}}{\hbar}} d^{3}p . \tag{132}\]

Where the gender subscripts means (M) male and (F) female. \(\xi^{s}(\mathbf{p})\) and \(\eta^{s}(\mathbf{p})\) are stochastic variables which are sampled according to the ensemble average relations \(\langle \xi^{s}(\mathbf{p})\xi^{s'}(\mathbf{p'}) \rangle = (2\pi\hbar)^{3}(1 - 2n_{p}^{+})\delta(\mathbf{p} - \mathbf{p'})\delta_{s,s'}\) and \(\langle \eta^{s}(\mathbf{p})\eta^{s'}(\mathbf{p'}) \rangle = (2\pi\hbar)^{3}(1 - 2n_{p}^{-})\delta(\mathbf{p} - \mathbf{p'})\delta_{s,s'}\), where the others correlators vanish. The ensemble model reconstructs the anticommutation relations of the fermion ladder operators in classical statistic regime. To describe the Dirac vacuum, we can assume these stochastic variables admit the same amplitude distribution \((\sqrt{(2\pi\hbar)^{3} - \sigma^{2}}, \sigma^{2})\) and uniform phase distribution \(U(-\pi, \pi]\) in the momentum space. To describe a single specie and spin polarized plasma background, we can set distributions of the stochastic variables \(\xi(\mathbf{p})\) and \(\eta(\mathbf{p})\) admit the Pauli blocking density. Then the ensemble averaged bilinear covariant gives rise to the background plasma density. Eqs. (131)-(132) ensure the statistically equivalence between ensemble model and field quantization for the Dirac
vacuum and non-trivial plasma backgrounds [30, 40]. Based on this ensemble model, the Lagrangian density Eq. (1) on $TG = (\psi_{MR}, \psi_{MI}, \psi_{FR}, \psi_{FI}, A, \phi, \dot{\psi}_{MR}, \dot{\psi}_{MI}, \dot{\psi}_{FR}, \dot{\psi}_{FI}, \dot{A}, \dot{\phi})$ can be rewritten as,

$$\mathcal{L} = -\frac{1}{2} \left\langle \psi_{M} \left( i\hbar \partial - mc^{2} \right) \psi_{F} + g.c. \right\rangle : -\frac{1}{16\pi} F_{\mu \nu} F^{\mu \nu}. \quad (133)$$

Where the gender conjugate $g.c.$ means commutation between the stochastic bispinor pairs, and $:\cdot:\$ means normal product. Then the Hamiltonian functional on $T^*G = (\psi_{MR}, \psi_{MI}, \psi_{FR}, \psi_{FI}, A, -\psi_{FI}/4N_{e}, \psi_{FR}/4N_{e}, -\psi_{MI}/4N_{e}, \psi_{MR}/4N_{e}, Y)$ can be obtained via the Legendre transformation as,

$$H = \int_{V} \left\{ -\frac{1}{2} \left\langle \psi_{M}^{+} \dot{H} \psi_{F} + g.c. \right\rangle : + \frac{1}{8\pi} \left[ 16\pi^{2} c^{2} Y^{2} + (\nabla \times A)^{2} - 8\pi c Y \cdot \nabla \phi \right] \right\} d^{3}x. \quad (134)$$

where $N_{e}$ is the ensemble capacity, and the canonical symplectic 2-form field is given as,

$$\Omega = -\frac{1}{2} \sum_{i=1}^{4} \left\langle d\psi_{MiR} \wedge d\psi_{FiI} + g.c. \right\rangle + \sum_{i=1}^{3} dA_{i} \wedge dY_{i}. \quad (135)$$

The Poisson algebra of this ensemble model can be constructed as,

$$\{F, G\} = \int_{V} \left[ \left( \frac{\delta F}{\delta \psi_{MR}} \right)^{T}, \left( \frac{\delta F}{\delta \psi_{FR}} \right)^{T}, \frac{\delta F}{\delta A}, \left( \frac{\delta F}{\delta \psi_{MI}} \right)^{T}, \left( \frac{\delta F}{\delta \psi_{FI}} \right)^{T}, \frac{\delta F}{\delta Y} \right] \Omega$$

$$\cdot \left[ \left( \frac{\delta G}{\delta \psi_{MR}} \right)^{T}, \left( \frac{\delta G}{\delta \psi_{FR}} \right)^{T}, \frac{\delta G}{\delta A}, \left( \frac{\delta G}{\delta \psi_{MI}} \right)^{T}, \left( \frac{\delta G}{\delta \psi_{FI}} \right)^{T}, \frac{\delta G}{\delta Y} \right]^{T} d^{3}x$$

$$= \int_{V} \left[ \frac{1}{2} \sum_{i=1}^{4} \left\langle \frac{\delta F}{\delta \psi_{FiI}} \frac{\delta G}{\delta \psi_{MiR}} - \frac{\delta G}{\delta \psi_{FiI}} \frac{\delta F}{\delta \psi_{MiR}} + g.c. \right\rangle + \frac{\delta F}{\delta A} \cdot \frac{\delta G}{\delta Y} - \frac{\delta G}{\delta A} \cdot \frac{\delta F}{\delta Y} \right] d^{3}x. \quad (136)$$

As a result of the general variational principle, the stochastic Dirac spinors $\psi_{F}$ and $\psi_{M}$ admit the same dynamical equations (23)-(30), and the Dirac current density $J$ in Eq. (32) is replace by the ensemble current form,

$$\left\langle J \right\rangle = -\frac{ec}{2} \left\langle \psi_{M}^{+} \alpha \psi_{F} + g.c. \right\rangle :. \quad (137)$$

The canonical symplectic structure-preserving geometric algorithms constructed in this work can be equipped with the ensemble model directly. It means that the calculations of the stochastic bispinors $\psi_{F}$ and $\psi_{M}$ using the updating schemes of $\psi$, and the discrete ensemble current density used for updating gauge field is given as,

$$\left\langle J_{x} \right\rangle = -\frac{ec}{2\hbar} \left\langle (\psi_{M1RJ+1} \psi_{F4RJ} + \psi_{M1JJ+1} \psi_{F4JJ} + \psi_{M2RJ} \psi_{F3RJ+1} + \psi_{M2J} \psi_{F3JJ+1}) \cos f_{j} \right.$$ 

$$+ (\psi_{M1JJ+1} \psi_{F4RJ} - \psi_{M1RJ+1} \psi_{F4JJ} - \psi_{M2J} \psi_{F3RJ+1} + \psi_{M2RJ} \psi_{F3JJ+1}) \sin f_{j} + g. \right\rangle. \quad (138)$$
\[ \langle J_y \rangle = -\frac{e c}{2\hbar} : \left( (\psi_{M1RJ+1}\psi_{F4IJ} - \psi_{M1IJ+1}\psi_{F4RJ} - \psi_{M2RJ}\psi_{F3IJ+1} + \psi_{M2IJ}\psi_{F3RJ+1}) \cos^y_j \right. \\
\left. + (\psi_{M1RJ+1}\psi_{F4RJ} + \psi_{M1IJ+1}\psi_{F4IJ} + \psi_{M2RJ}\psi_{F3RJ+1} + \psi_{M2IJ}\psi_{F3RJ+1}) \sin^y_j + g.c. \right) \],

\[ \langle J_z \rangle = -\frac{e c}{2\hbar} : \left( (\psi_{M1RJ+1}\psi_{F3RJ} + \psi_{M1IJ+1}\psi_{F3IJ} - \psi_{M2RJ}\psi_{F4RJ+1} - \psi_{M2IJ}\psi_{F4RJ+1}) \cos^z_j \right. \\
\left. + (\psi_{M1IJ+1}\psi_{F3RJ} - \psi_{M1RJ+1}\psi_{F3IJ} - \psi_{M2RJ}\psi_{F4IJ+1} + \psi_{M2IJ}\psi_{F4RJ+1}) \sin^z_j + g.c. \right) \].

To keep the physical constraints, the sampling of gauge field configuration should adapt the self-consistent field condition at initial time. We should emphasize that the gauge field can be treated as a classical field without quantum fluctuation only valid in very high occupation states. The SFQED and RQP phenomena always satisfy this condition. When it comes to weak field problems, e.g. some quantum optics and quantum electronics phenomena, the strong-field condition breaks and the quantization of gauge field should also be taken into consideration.

V. REAL-TIME LCFT SIMULATIONS

A. Energy spectra

To verify the canonical symplectic structure-preserving geometric algorithms constructed in this work, we implement the code to obtain a class of numerical energy spectra of the Dirac-Maxwell theory based LCFT. As benchmarks, the analytical dispersion relations of linearized scalar QED are introduced to compare with these numerical energy spectra [6,14]. The dispersion relation of free Dirac fermions are given as [90],

\[ \omega = \pm \sqrt{c^2 k^2 + \frac{m^2 c^4}{\hbar^2}}, \]  

(141)

which means that there are two fermion modes sharing a gap \(2mc^2/\hbar\). The Dirac double-cone of positive and negative states is a basic property of relativistic particles. If there is no strong background magnetic field, e.g. the vacuum and unmagnetized plasmas, the Klein-Gordon-Maxwell (KGM) theory based scalar QED is a good toy model of the Dirac-Maxwell fields theory, both of which admit the same branches of linearized dispersion relations. The 1/2-spin effects only modify the mode structures. The tree-level electromagnetic mode dispersion relation of the scalar QED can be given as [14],

\[ \omega^2 = c^2 k^2 + \omega_p^2. \]  

(142)
Where $\omega_p$ is the plasma frequency of background fermions. When it comes to the vacuum, $\omega_p = 0$ and Eq. (142) reduces to the light cone. The tree-level dispersion relation of electrostatic mode can be given as [6],

$$
\left(\omega^2 - c^2 k^2\right) \left(\omega^2 - c^2 k^2 - \omega_p^2\right) - 4 \frac{m^2 c^4}{\hbar^2} \left(\omega^2 - \omega_p^2\right) = 0.
$$

Eq. (143) shows that the electrostatic mode consists of four branches. In vacuum, two gapless branches relate to the fermions moving with self gauge fields, which are known as Langmuir modes. The other two gapped branches are pair modes, and the half gap $2mc^2/\hbar$ means that if the photon energy $\hbar\omega > 2mc^2$, the fermion pairs will be generated and the quanta of these pair plasmas have finite group velocities. The pair mode is also known as Zitterbewegung effect in relativistic quantum mechanics, which is described as the interference between positive and negative states of a fermion on the Compton space-time scale.

FIG. 2. Numerical dispersion relation of a free fermion. (a) The Dirac double-cone in the BZ of a DEC lattice. Different from the Dirac double-cone in continuous space-time, the exact dispersion relation of the LCFT shown here is modified near the BZ boundary. It can be find that each branch of the spectra has only one cone centered at the origin of BZ. As a result, there is no extra pseudo-fermion modes and the numerical schemes are fermion doubling free. (b) The numerical dispersion relation (contour plot) of a free fermion obtained by a real-time LCFT simulation shows good consistency with the analytical one (solid line for positive state and dashed line for negative state). The energy gap $2m$ between positive and negative states is perfectly recovered. ($m = 0.25, \Delta t = 0.5, \Delta x_i = 1, N_t = 512, N_x = N_y = 1, N_z = 256$)

To implement real-time LCFT simulations, the natural units are used, where the constants $\hbar = c = 1$, the elementary charge $e = 0.0854$, so that the fine structure constant $\alpha = e^2/\hbar c \approx 1/137$ is physically correct. Then all physical variables can be normalized by a unified dimension, such as [M]. Here we employ the fermion mass $m = 0.25$, the energy
FIG. 3. Numerical energy spectra (contour plot) obtained by a real-time LCFT simulation. (a)-(b) Energy spectra of $E_x$ and $E_y$, where the light cone (solid line) is well traced by the analytical electromagnetic mode dispersion. Distinguished from the 0-spin scaler QED model, the existence of pair and Langmuir modes (dashed and circle lines) implies the field structures of these two modes are polarization hybrid. (c) Energy spectrum of $E_z$, where the gapped pair mode (dashed line) and gapless Langmuir mode (circle line) are well traced by the analytical electrostatic mode dispersion. The energy gap $2\tau_m$ is a threshold beyond which pair plasmas will be generated. (d) Energy spectrum of $\psi_{1R}$. The weak self gauge field dressed bispinor spectrum is well traced by a free fermion dispersion (solid line). ($m = 0.25, \Delta t = 0.5, \Delta x_i = 1, N_t = 512, N_x = N_y = 1, N_z = 256$)

dimension is $[M]$, and the dimension of length and time is $[M]^{-1}$. To calculate the energy spectra, a uniform $1 \times 1 \times 256(N_x \times N_y \times N_z)$ DEC lattice is introduced, where the spatial lattice periods $\Delta x = \Delta y = \Delta z = 1$, and the temporal lattice period $\Delta t = 0.5$. In all directions, the periodic boundary is used to naturally introduce an infrared truncation. The simulations are implemented with vacuum background. To initialize the simulations so that a broad spectrum of linear waves are excited, the bispinor field is given using small amplitude unbiased white noise with standard deviation $\sigma = 1 \times 10^{-6}$. After a $N_t = 512$ steps simulation, the numerical spectra of the LCFT can be read out from simulation results by taking fast Fourier transforms (FFT) of bispinor and electric field components on the $t-z$ submanifold. By abandoning the gauge field in simulation, we can obtain the dispersion relation of a free fermion via the same procedure.

Fig. 2 illustrates the numerical dispersion relation of a free fermion in the LCFT. The
Dirac double-cone shown in Fig. 2 (a) is an exact result derived from the linearized LCFT, which can be seen as a massive fermion extension of Eq. (124). Different from the bispinor field in continuous spacetime manifold, the shape of numerical Dirac double-cone is modified near the boundary of lattice BZ. The dispersion relation (contour plot) shown in Fig. 2 (b) is obtained by a simulation, where the benchmark line is a projection of the numerical Dirac double-cone. It can be find that the dispersion relation and the energy gap $2m$ of a free fermion is perfectly recovered. The numerical result also shows that there is only one Dirac double-cone centered at the origin of BZ, which means that the structure-preserving geometric algorithms are fermion doubling free. The dispersion relations obtained by a simulation shown in Fig. 3 provide us with a complete numerical energy spectra of the Dirac-Maxwell theory based LCFT. The momentum in these plots is cut off at $k = 4m$ ($k\Delta z \approx 1$) where the continuous approximation is no longer sufficient. The numerical energy spectrum (contour plot) of $E_z$ shown in Fig. 3 (c) is well traced by the analytical electrostatic mode dispersion, where the dashed line indicates gapped pair mode (energy gap $2m$) and the circle line indicates gapless Langmuir mode. The numerical energy spectra (contour plot) of $E_x$ and $E_y$ plotted in Fig. 3 (a)-(b) show three different branches, where the well traced light cone (solid line) is the typical dispersion of a tree-level electromagnetic mode, and the distinct pair (dashed line) and Langmuir (circle line) modes imply that the field structures of these two modes are polarization hybrid. The hybrid polarization originates from 1/2-spin induced polarization currents hybridization, which is distinguished from the 0-spin KGM theory. Fig. 3 (d) shows a weak self gauge field dressed fermion mode, which can be well traced by the free fermion dispersion. That the analytical dispersion relations are recovered by numerical spectra indicates that our solutions faithfully capture the propagation of linear waves up to the lattice resolution.

To illustrate the advantages of our algorithms, we implement a long-term 3-dimensional simulation and record the numerical errors of the conserved quantities. The simulation domain is a uniform $10 \times 10 \times 10$ DEC lattice, and the the periodic boundary is used in all directions. $\Delta x = \Delta y = \Delta z = 1$, and $\Delta t = 0.05$. At initial time, a unbiased white noise with standard deviation $\sigma = 3 \times 10^{-2}$ is introduced into the bispinor field. After a million steps simulation, the relative numerical errors of the total Hamiltonian and total probability are plotted in Fig. 4. We find that after a extremely long-term simulation, the numerical errors of conserved quantities are bounded by small values without coherent
accumulation. The excellent conservation property in these numerical solutions comes from the preservation of geometric structures and symmetries by using our algorithms. The conservation is a footstone to implement secular simulations for nonlinear multi-scale SFQED and RQP phenomena.

**B. Schwinger mechanism induced $e^{-}e^{+}$ pairs creation**

The Schwinger mechanism induced creation and annihilation of electron and positron pairs are genuine phenomena in SFQED, which can not be described via classical theories \[97\]. In Sec. V A, the numerical spectra show that the pair mode can be find once the energy of the $\gamma$ photon exceeds double electron rest energy. Schwinger effect states that when the photon wavelength is not very short, the $e^{-}e^{+}$ pair can also be generated once the gauge field strength is extremely strong \[10, 90\]. The typical electrostatic field strength of the Schwinger limit is $E_S = 1.32 \times 10^{16}$ V/cm, and the equivalent magnetic field strength and laser intensity are of orders $10^9$ T and $10^{29}$ W·cm$^{-2}$ respectively \[10\]. Beyond the Schwinger threshold, the virtual $e^{-}e^{+}$ pairs can be pulled apart from quantum fluctuations on the Compton spacetime scale and large on shell $e^{-}e^{+}$ pairs can be created from the vacuum. Although there are some other QED mechanisms can create on shell $e^{-}e^{+}$ pairs in the vacuum, e.g. the Breit-Wheeler process, the Schwinger effect becomes the dominate process once the $U(1)$
gauge field becomes a low frequency and extremely strong field. The Feynman diagram of Schwinger effect is shown in Fig. 5.

FIG. 5. The Feynman diagram of Schwinger effect. In order to calculate the Schwinger pair production, one should sum the infinite set of diagrams, each of which contains one electron loop and any number of external photon legs.

To simulate the Schwinger mechanism induced $e^-e^+$ pair creation, we set a longitudinal quasi-static electric field whose strength is normalized by the Schwinger limit $E_S = m^2/e$. Numerical experiments are implemented on a $1 \times 1 \times 256$ uniform DEC lattice, and the periodic boundary is used in all directions. $e/m = 0.2$, $\Delta x = \Delta y = \Delta z = 0.05/m$, and $\Delta t = 0.5\Delta x_i$. At initial time, an ensemble model based Dirac vacuum state is introduced by sampling a class of stochastic Dirac spinors $\psi_M(x,0)$ and $\psi_F(x,0)$ as $n_p^+ = n_p^- = 0$, where the ensemble capacity $N_e = 512$. The gauge field $A^\mu$ is sampled in the temporal gauge, where $A(x,0) = 0$ and $Y(x,0) = (0,0,0,-E_S/4\pi)$ are given as an initial condition. By setting $Y(x,0) = 0$, we can also simulate the quantum fluctuations of Dirac vacuum. After a 20000 steps simulation, the numerical results are recorded, which include the electric field evolution, pair production rate, Hamiltonian transfer, and spectral density.

Fig. 6 illustrates the numerical evolution of normalized Hamiltonians, where the vacuum energy has been renormalized by the normal product. The blue solid line show us the decaying oscillation of the $U(1)$ gauge field. During this process, on shell $e^-e^+$ pairs are continuously created and driven, and the energy of photons is continuously transferred into the fermions energy. With the growth of fermion density, the pair plasma frequency increases and the chirp feature of the plasma oscillation can be distinctly recognized from the Hamiltonian of gauge field. This is a nonlinear phenomenon, as the production of $e^-e^+$ pair can be effectively suppressed by the radiation reaction, which means that the energy of gauge field will be absorbed by self generated pair plasmas and the pair production will reach a saturation level. This nonlinearity can also be read out from the fermion Hamiltonian (red
The lower envelope of this curve told us that the production rate of the $e^{-}e^{+}$ pair in the simulation domain has a very high level in the early time of the vacuum breakdown ($t \cdot m \sim 50$), and then the pair production rate is saturated with a relatively stable plasma frequency after a long time evolution ($t \cdot m \sim 500$). During this nonlinear Schwinger process, the total Hamiltonian in the simulation domain is perfectly conserved (black solid line). In summary, the photon energy is continuously absorbed by new on shell $e^{-}e^{+}$ pairs, and the energy between photon and pair plasmon is exchanged cycle by cycle with a chirped plasma frequency.

FIG. 6. Numerical evolution of different parts of the QED Hamiltonian (normalized by total Hamiltonian). The total Hamiltonian $H_t$ (black solid line) of the interacting fermion-boson system is perfectly conserved in this long-term simulation, which is a result of the preservation of the geometric structures and Poincaré symmetry. The energy transfer between $e^{-}e^{+}$ pair plasmas and $U(1)$ gauge field can be read out from the fermionic sector $H_F$ (red dashed line) and gauge sector $H_G$ (blue solid line) of the total Hamiltonian. The nonlinear envelopes of these curves demonstrate that the pair production experienced a process from rapid growth to saturation, where the nonlinear suppression comes from the nonperturbative field backreaction and Pauli exclusion effect. With the increase of fermion density, the plasma frequency will exhibit blue shift, which can be find as the chirp features in these Hamiltonian curves. ($e/m = 0.2, \Delta x_i = 0.05/m, \Delta t = 0.5\Delta x_i, N_t = 2 \times 10^4, N_x = N_y = 1, N_z = 256, N_e = 512$)

Moreover, we plot the gauge connection $A_z$, electric field $E_z$, net charge $Q$ and Dirac current density $\mathcal{J}_z$ in Fig. 7 to demonstrate the dynamical properties of $U(1)$ gauge field and fermions. The numerical evolution of gauge field shown in Fig. 7 (a)-(b) illustrates the
FIG. 7. Dynamical properties of $U(1)$ gauge field and fermions. (a)-(b) Numerical evolution of gauge connection $A_z$ and associated electric field $E_z$ (normalized by $E_S$). The chirped electric field exhibits dissipative anharmonic feature, which can be used as a probe to diagnose the state of $e$-$e^+$ pair oscillators. In this simulation ($t \sim 500/m$), the electric field amplitude approaches $0.68E_S$, which means that more than half of the gauge field energy has been consumed to create $e$-$e^+$ pairs. All QED phenomena admit the charge conservation law, which means that the net charge $Q$ in Schwinger process must keep 0. It can be find in subfigure (c), where a numerical noise induced extremely small net charge is well conserved in the simulation. (d) shows the pair plasma oscillation induced ensemble current density. With the nonlinear increase of fermion density, the current amplitude experienced a growth process with a decay rate. Obviously, the chirped oscillations of current and electric field are well matched with a $\pi/2$ phase difference. ($e/m = 0.2, \Delta x_i = 0.05/m, \Delta t = 0.5\Delta x_1, N_t = 2 \times 10^4, N_x = N_y = 1, N_z = 256, N_e = 512$)

dissipative anharmonic effects induced by the separation and recombination of nonlinear $e$-$e^+$ pair oscillators. From the Hamiltonian curves plotted in Fig. 6, we already know that after hundreds of Compton periods $1/m$, the pair production will be effectively suppressed by the nonperturbative field backreaction. In Fig. 7 (b), we find a slowly varying electric field amplitude $E_z \approx 0.68E_S$ at the end of this simulation. During this time, more than half of the gauge field energy has been consumed to create $e$-$e^+$ pairs, and the consumed energy is transferred and stored in the pair plasmas. Gauge symmetry induced charge conservation law can be find in Fig. 7 (c), where an extremely small net charge $Q$ in the simulation domain is well conserved in this simulation. The fermion and antifermion are created and annihilated in pairs during the Schwinger process. As a result, the net charge in whole space
must keep 0. The well bounded weak numerical noise of $Q$ exhibits advanced long-term performance of our structure-preserving algorithms in simulating complicated relativistic quantum effects. The ensemble current density of pair plasmon shown in Fig. 7 (d) provide us with an intuitive picture of the pair plasma motion. Just as a classical plasma oscillator, the oscillations of current and electric field are well matched with a $\pi/2$ phase difference. Different from the classical oscillator, the nonlinear increase of pair plasma density gives rise to a nonlinear current amplitude growth and an oscillation frequency blue shift.

FIG. 8. Numerical evolution of fermion Hamiltonians (normalized by total Hamiltonian with background electric field $E_S$) with different background gauge field strengths. The lower envelopes of these Hamiltonian curves can be used as an indicator of the pair production rate. It shows that when the background electric field approaches $0.5E_S$, the Schwinger effect becomes negligible. With a background electric field stronger than $E_S$, the pair plasmas can be quickly generated and then saturated by the nonlinear radiation backreaction in a relatively short period. ($e/m = 0.2, \Delta x_i = 0.05/m, \Delta t = 0.5\Delta x_i, N_t = 2 \times 10^4, N_z = N_y = 1, N_z = 256, N_e = 512$)

To compare the Schwinger effect with different background gauge field strengths, we implement a class of simulations under different initial electric fields (normalized by $E_S$), and plot the associated fermion Hamiltonian curves in Fig. 8. The lower envelope of the curve with $E_z = 0.6$ demonstrate that the Schwinger effect can be effectively cut off when the background electric field is lower than half $E_S$. In this situation, the extremely tenuous fermion density gives rise to a very low plasma frequency, and the energy transfer from photons to fermions is very slow. On the contrary, the lower envelope of the curve with $E_z = 1.4$ shows us that the nonlinear suppression effect in Schwinger process can be significantly enhanced when the background electric field is far stronger than $E_S$. 

36
Finally, we can make a brief summary that the Schwinger mechanism induced fermion pairs production is inherently a nonlinear and non-perturbative phenomenon, which exhibits abundant anharmonic, non-equilibrium and self-modulation features. To illustrate the complete physics of this process, real-time LGT simulation or other non-perturbative methods are needed. Due to the symmetric and geometric structure-preserving nature, our algorithm provides an efficient, accurate, stable and conservative approach to implement real-time LCFT simulations to study this kind of complicated SFQED phenomena.

C. Vacuum Kerr effect

The Schwinger mechanism induced pair plasmas are strongly polarized, which means that the Dirac vacuum is strongly polarized under an extreme electric field. The Kerr effect states that when a dielectric medium is polarized by an external electric field, it will exhibit birefringence property, for the refractive index parallel to external electric field is modulated. Be treated as an QED analogue of the classical polarized dielectric medium, the polarized Dirac vacuum may also exhibit birefringence property, and a Kerr-like effect can be expected to be observed in the SFQED regime. A schematic of the vacuum Kerr effect is shown in Fig. [9].

![Schematic of the vacuum Kerr effect. The Dirac vacuum is strongly polarized under an extreme electric field whose strength approaches the Schwinger threshold. Just as the birefractance in a polarized dielectric medium, a linear polarized FEL beam can transfer into an elliptical polarized beam after it propagating through the polarized vacuum.](image-url)
To simulate the vacuum Kerr effect, we set a transverse quasi-static electric field whose strength approaches $E_S$, and then introduce a weak linear polarized free electron laser (FEL) beam as incident wave. Numerical experiment is implemented on a $40 \times 40 \times 20$ uniform DEC lattice, and the periodic boundary for both fermion and gauge field is used in $x$ and $y$ directions. To cut off the longitudinal radiations, we introduce the second order Mur’s boundary in $z$ direction to simulate a open space.

At initial time, an ensemble model based pair plasma state is introduced by sampling the stochastic bispinors $\psi_M(x,0)$ and $\psi_F(x,0)$ as $n^+_p = n^-_p = 0.1$, where the ensemble capacity $N_e = 3200$. The gauge field $A^\mu$ is sampled in the temporal gauge, where $A(x,0) = 0$ and $Y(x,0) = (0, 0, -E_S/4\pi)$ are given as an initial condition. To excite an incident FEL plane wave, we set a total-scattered fields boundary in the $z = 5\Delta z$ (source) plane, and the laser frequency is given as $\omega = 0.2\pi m$. After a 400 steps simulation, the numerical results are recorded, where the trace of magnetic field vector in the $z = 15\Delta z$ (target) plane demonstrates the polarization state of the beam.

Fig. 10 illustrates the conversion of FEL polarization states in the source and target planes. The incident FEL beam is a $3\pi/4$ linear polarized plane wave, which can be find in Fig. 10 (b), where the trace of magnetic field vector in the source plane draws a perfect line segment. When propagating throw the strongly polarized Dirac vacuum, the $x$ and $y$ components of the FEL beam have different phase velocities. Then there is a phase difference between $x$ and $y$ modes in the target plane, and the beam polarization will transferred into a elliptical-like state, which can be find in Fig. 10 (d). From the numerical results of Schwinger mechanism induced $e^+e^-$ pairs creation, we know that the pair plasma density and the background electric field strength are time dependent. As a result, the Vacuum Kerr effect admits a varying coefficient and the phase difference is time dependent. The insets of Fig. 10 (d) demonstrate this feature, where the second cycle (C2) of the beam admits a larger semi-major axis than the first cycle (C1), and the trace gyrocenter is drifting perpendicular to the major axis. If the pair plasma is dense enough, more significant polarization conversion features can be expected to be observed.

In summary, the numerical experiments illustrated in Sec. V cover relativistic QED wave structures, fermion pairs creation and annihilation effects, self-consistent interactions between fermion plasmas and $U(1)$ gauge field, nonlinear and non-perturbative nature of strong-field physics. The good properties of these numerical solutions ensure the structure-
FIG. 10. Vacuum Kerr effect induced FEL polarization conversion from linear to elliptical-like states. (a) The magnetic field components in the source plane, where the blue solid line denotes $B_x$ and the red dashed line denotes $B_y$. (b) The trace of magnetic field vector in the source plane is a line segment, which means that the incident FEL plane wave is linear polarized (fine structure of the trace can be find in the inset). (c) The magnetic field components in the target plane, where the blue solid line denotes $B_x$ and the red dashed line denotes $B_y$. (d) The trace of magnetic field vector in the target plane exhibits elliptical shape with varying parameters (insets illustrate fine structures of the trace, where C1 and C2 denote the first and the second cycles of the beam respectively), which means that the Dirac vacuum exhibits birefringence property and the birefringence index is time dependent. The magnetic field vectors plotted here are normalized by the incident wave. ($\epsilon/m = 0.2, \Delta x_i = 0.1/m, \Delta t = 0.5 \Delta x_i, \omega = 0.2\pi m, N_t = 400, N_x = N_y = 40, N_z = 20, N_e = 3600$)

preserving real-time LCFT simulation method is expected to be a unified first-principle based theoretical tool in studying SFQED and RQP phenomena.
VI. CONCLUSION AND OUTLOOK

In this paper, we developed a class of high-order canonical symplectic structure-preserving geometric algorithms for simulating the quantized Dirac-Maxwell theory based SFQED and RQP. We constructed a canonical field theory of the Dirac-Maxwell systems, and obtained the canonical symplectic form and Poisson algebra admitted by this field theory. Based on the Noether’s theorem, this field theory admits charge, energy-momentum and angular momentum conservation laws via the gauge and Poincaré symmetries. In DEC framework, we constructed a LCFT which is a good semi-discrete analogue of the continuous canonical field theory. The $U(1)$ gauge field is discreted to form a cochain complex which guarantees the Bianchi identities of the $U(1)$ gauge theory. With the Hodge dual relations, the bispinor field components are discreted as four different differential forms, which naturally generate a staggered checkerboard-like lattice. Two kinds of discrete gauge covariant derivatives, i.e. pull-back and push-forward, are used to construct a gauge invariant semi-discrete action. A well-defined discrete Poisson bracket is constructed, which admits bilinearity, anticommutativity, product rule, and Jacobi identity. With the previous numerical techniques, the semi-discrete LCFT is gauge and Poincaré invariant, which also preserves the canonical symplectic and unitary structures. By using the Hamiltonian splitting method, we obtained three linear subsystems which can be solved independently, and constructed a class of high-order structure-preserving geometric algorithms via the Cayley transformation and symmetric composition technique. The algorithms preserve the symmetries and geometric structures of the semi-discrete LCFT. We proved that the numerical dispersion of the mass free fermions subsystem has only one Dirac double-cone centered at the origin of BZ, which means there is no fermion doubling problem in our algorithms. The locally unconditional stable property can also be obtained from the numerical dispersion. To simulate the quantization of Dirac field to achieve a correct Fermi-Dirac statistics, we introduce an unified statistically quantization-equivalent ensemble model to describe the Dirac vacuum and non-trivial plasma backgrounds. Although the algorithms are unconditional stable, it does not means that the lattice periods can be chosen arbitrary large values. On the one hand, some basic physics can not be captured if the lattice periods exceed the typical space-time scales, such as the Compton scale. On the other hand, large lattice periods will lead to sparse matrices with very large condition numbers, which are very expensive for matrix inversion.
Additionally, the topology of the $U(1)$ gauge field is changed into a torus by the Wilson lines, which means that the lattice periods should not be too large to avoid topological modes.

The numerical energy spectra of the LCFT were calculated and compared with the analytical dispersion relations of linearized scalar QED. Simulation results show that the relativistic quantum wave dynamics and the vacuum responses can be captured perfectly. The gapless lower branches (Langmuir) of electrostatic mode relate to the fermions moving with self gauge fields. The gaped higher branches of electrostatic mode are QED pair modes, where the virtual fermion pairs in quantum fluctuations are generated. As the quanta of pair plasmas, the pair plasmons have finite group velocities, which means the virtual pairs created and annihilated on the Compton space-time scale are very different from the classical plasmas. The nonlinear Schwinger effect was also simulated to illustrate the power of our algorithms. To simulate the quantum fluctuations, we introduced an ensemble of statistically quantization-equivalent initial conditions via random momentum and phase, which can be used as a statistical model of the quantized Dirac vacuum. With a uniform strong field, the pair production rate is obtained with a nonlinear suppression, which means that the energy of the gauge field will be absorbed by self generated pair plasmas and the pair creation will reach a saturation level. This nonlinear property of Schwinger mechanism can only be resolved by non-perturbative methods, such as the quantum particle-in-cell (PIC) and real-time LQED methods $[5, 30, 98]$. Our algorithms provide a more accurate and efficient solver for simulating these SFQED and RQP problems because of the advanced conservation performance in secular simulations and good unconditional stable property. We also simulated the vacuum Kerr effect, where the vacuum response can be resolved. After propagating through a strongly polarized vacuum area, a linear polarized FEL beam transferred into an elliptical polarized one, where the vacuum birefringence property was well traced. Because the vacuum polarization state is strongly affected by the evolution of background electric field, the birefringence index of polarized Dirac vacuum is time dependent. This dynamical property can only be resolved by nonlinear non-perturbative methods. All simulations implemented in this work show a common property that the numerical errors of conserved quantities, e.g. total Hamiltonian and charge, are bounded by a very small value after a long-term simulation. This advantage enables us to simulate nonlinear multi-scale problems dominated by relativistic quantum effects, such as a high energy FEL beam interacting with RQP and the the magnetosphere of an X-ray pulsar.
In summary, the gauge and Poincaré invariant canonical symplectic structure-preserving geometric algorithms constructed in this work provide us with a powerful first-principle based theoretical tool to implement quantized Dirac-Maxwell theory based real-time LCFT simulations. Because of the nonlinear and non-perturbative nature of this approach, it can bring abundant physics from the interacting fields. With well-designed field quantization models, this method opens a new door toward high-quality simulations in SFQED and RQP fields.

ACKNOWLEDGMENTS

This work is supported by the National Nature Science Foundation of China (NSFC-11805273). Numerical simulations were implemented on the ShenMa high performance computing cluster in Institute of Plasma Physics, Chinese Academy of Sciences and the TH-1A supercomputer at National Super Computer Center in Tianjin.

Appendix A: Wigner Function Based Pseudo Distributions and Observables

The observables of electron and positron, e.g. particle numbers and Hamiltonian densities, are hard to read out from the bispinor field directly. To get these important observables, the Dirac-Heisenberg-Wigner (DHW) theory can be introduced as an auxiliary tool, where the Wigner function is recognized as a linear map from real space to phase space \[99\]. The Wigner function transforms operators in real space into pseudo distributions in phase space. Taking number density and Hamiltonian for example, the map can be given as,

\[
\rho(x, p) \triangleq \int_{-\infty}^{\infty} -\frac{1}{2} \left< \psi_M^+ \left( x - \frac{x'}{2} \right) \psi_F \left( x + \frac{x'}{2} \right) + g.c. \right> e^{i \frac{p \cdot x'}{\hbar}} d^3x',
\]

\[
H(x, p) \triangleq \int_{-\infty}^{\infty} -\frac{1}{2} \left< \psi_M^+ \left( x - \frac{x'}{2} \right) \hat{H} \psi_F \left( x + \frac{x'}{2} \right) + g.c. \right> e^{i \frac{p \cdot x'}{\hbar}} d^3x'.
\]

We should emphasize that Eqs. (A1)-(A2) are nonphysical, for they contradict Heisenberg’s uncertainty principle. But these pseudo distributions can help us to construct useful physical observables. The pseudo distribution of electron and positron can be given as,

\[
\rho^\pm(x, p) = \frac{H(x, p) - H_{vac}(x, p)}{2\hbar \omega_p} \pm \hbar \omega_p \rho(x, p).
\]
Where the spectral energy \( \hbar \omega_p = \sqrt{(e \mathbf{p} - e \mathbf{A})^2 + m^2 c^4} \), and \( H_{\text{vac}} \) means pseudo distribution of vacuum Hamiltonian. Eq. (A3) can be used as an approximate evaluation of the local spectral pair production. The physically correct local and total pair productions are obtained as,

\[
\rho^\pm (\mathbf{x}) = \frac{1}{(2\pi \hbar)^3} \int_{-\infty}^{\infty} \rho^\pm (\mathbf{x}, \mathbf{p}) \, d^3p, \quad (A4)
\]

\[
n^\pm = \int_{-\infty}^{\infty} \rho^\pm (\mathbf{x}) \, d^3x. \quad (A5)
\]

The other observables of electron and positron can be obtained via the same procedure.
