Abstract
Deltamethrin (DLM) is a widely used and highly effective insecticide. DLM exposure is harmful to animal and human. Quail, as a bird model, has been widely used in the field of toxicology. However, there is little information available in the literature about quail cerebrum damage caused by DLM. Here, we investigated the effect of DLM on quail cerebrum neurons. Four groups of healthy quails were assigned (10 quails in each group), respectively given 0, 15, 30, and 45 mg/kg DLM by gavage for 12 weeks. Through the measurements of quail cerebrum, it was found that DLM exposure induced obvious histological changes, oxidative stress, and neurons apoptosis. To further explore the possible molecular mechanisms, we performed real-time quantitative PCR to detect the expression of endoplasmic reticulum (ER) stress-related mRNA such as glucose regulated protein 78 kD, activating transcription factor 6, inositol requiring enzyme, and protein kinase RNA (PKR)-like ER kinase. In addition, we detected ATP content in quail cerebrum to evaluate the functional status of mitochondria. The study showed that DLM exposure significantly increased the expression of ER stress-related mRNA and decreased ATP content in quail cerebrum tissues. These results suggest that chronic exposure to DLM induces apoptosis of quail cerebrum neurons via promoting ER stress and mitochondrial dysfunction. Furthermore, our results provide a novel explanation for DLM-induced apoptosis of avian cerebrum neurons.

Keywords
apoptosis, Deltamethrin, endoplasmic reticulum stress, mitochondria dysfunction, quail cerebrum neurons

1 INTRODUCTION

Deltamethrin (DLM) is a kind of type II synthetic pyrethroids, which is used to drive or kill arthropods, such as flies, ticks, lice, and some mites.\textsuperscript{1,2} Among pyrethroids, DLM is considered one of the safest available insecticides.\textsuperscript{3} However, numerous recent reports indicate that DLM is an environmental and industrial pollutant and it is toxic to non-aimed organisms living in the same ecosystem.\textsuperscript{4,5} DLM can
induce neurotoxicity in many species including human, and DLM exposure is related to neurodegenerative diseases.6,7

Endoplasmic reticulum (ER) is one of the membrane organelles in eukaryotic cells, integrating a variety of functions such as regulation of calcium (Ca2+), synthesis and maturation of proteins, biosynthesis of lipids, and maintenance of cell homeostasis.8 ER stress, as a protective stress response in eukaryotic cells, can be activated by the imbalanced homeostasis.9 Once ER stress arises, excessive improperly folded proteins accumulate in the ER lumen.10 The unfolded protein response (UPR) then occurs, which is sensed and activated by three transmembrane proteins, activating transcription factor 6 (ATF6), inositol requiring enzyme (IRE), and protein kinase RNA (PKR)-like ER kinase (PERK).11 UPR plays a crucial role in the restoration of ER homeostasis. However, if ER stress is sustained or serious, UPR will trigger apoptosis.12 In addition, ER stress increases the accumulation of reactive oxygen species (ROS) in cells.13 ROS can induce oxidative stress, which can lead to apoptosis.14 Mitochondria, as essential organelles in cells, play a vital role in energy production and calcium homeostasis regulation. More importantly, mitochondria are the regulatory center of apoptosis, controlling apoptosis via releasing Cytochrome C (Cyt C), activating cysteine proteases, changing calcium flux, decreasing ATP pool, and producing excess ROS.15 The mitochondrial pathway, one of the classic apoptotic pathways, is easily activated by numerous stimuli, thereby inducing apoptosis.16,17 Mitochondria and ER are important target organelles for studying apoptosis and they are closely related to cell survival.18

As a crucial part of cerebrum, neuron is the most basic structure and function unit of nervous system. Neuronal damage is a crucial mechanism of neurological diseases.19 According to report, DLM can increase the risk of Parkinson’s disease, learning disabilities, and Alzheimer’s disease.20 DLM interacts with cell Na+ channels causing an increase of intracellular Ca2+ and activation of the ER stress pathway.21 Simultaneously, high concentration of Ca2+ might trigger mitochondrial permeability transition pore opening.22 Cyt C, apoptosis-inducing factor (AIF) and other apoptotic factors enter the cytoplasm through the open mitochondrial permeability transition pore. Cyt C and AIF activate the caspase pathway causing apoptosis.23

However, there may be a connection between mitochondrial apoptotic pathway and ER stress apoptotic pathway, which makes them jointly involved in apoptosis process. DLM-induced neuronal apoptosis in rats, mice, and fish has been reported.21,24 However, there are a few studies on DLM-induced quail neuron apoptosis,25 and the specific mechanism of DLM-induced neuronal apoptosis remains unclear.

In this study, we aim to investigate the effect of long-term DLM exposure on neurons of quail cerebrum, and explore the role of ER stress and mitochondrial dysfunction in the progress of quail neuronal apoptosis. We hope to provide a new insight for further elucidating the specific mechanism of avian neuronal apoptosis caused by DLM.

## 2 MATERIALS AND METHODS

### 2.1 Animal and experimental protocol

Forty healthy male quails (average body weight of 80 ± 10 g, 21 days old) were purchased from Wanjiu Farm in Harbin, China. The quails were managed in the animal room of Northeast Agricultural University with the standard laboratory conditions (temperature 22 ± 2°C, light 12 h/ dark 12 h cycle, relative humidity 55 ± 5%). Food and water were obtained freely throughout the entire experiment.26,27

After a week of adaptive feeding, four groups of quails were randomly assigned (n = 10 per group): control group (normal saline administered by gavage), low dose (15 mg/kg DLM administered by gavage), medium dose (30 mg/kg DLM administered by gavage), and high dose (45 mg/kg DLM administered by gavage). Treatment duration was 12 weeks. The quails were euthanized and their cerebrum tissues were quickly dissected.28 Some fresh cerebrum tissues were used for the analysis of malondialdehyde (MDA), glutathione (GSH), and superoxide dismutase (SOD). The remaining cerebrum tissues were stored in 4% paraformaldehyde solution and −80°C refrigerator.29 Our animal experimental procedure was authorized by the Ethical Committee for Animal Experiments (Northeast Agricultural University, Harbin, China) and the IACUC number is 20200818.

### 2.2 Chemicals

DLM was purchased from Nanjing Red Sun Co., Ltd. (Nanjing, China). MDA, GSH, SOD, and ATP determination kits were provided by Nanjing Jincheng Bioengineering Research Institute (Nanjing, China). The terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) assay kit was obtained from Roche (Germany). The DAB kit was purchased from Bude Biotechnology Co., Ltd (Wuhan, China). GAPDH was provided by Hangzhou Goodhere Biotechnology Co., Ltd (Hangzhou, China). Primary antibodies against B-cell lymphoma gene 2 (Bcl-2), Bcl-2-associated X protein (Bax), caspase-3, were purchased by Bios Biotechnology (Beijing, China), ABclonal (Wuhan, China), and Abcam (Cambridge, UK). Bicinchoninic acid (BCA) protein assay kit, RIPA, and PMSF were obtained from Beyotime Institute of Biotechnology (Shanghai, China).

### 2.3 Histopathological analysis

Quail cerebrum tissues were soaked with 4% paraformaldehyde for 48 h, embedded in paraffin and sectioned in 0.5 μm thickness. Cerebrum tissue sections were fixed on glass slides, then dewaxed and stained with hematoxylin and eosin (H&E). Finally, the sections were fixed with neutral resin. In addition, the pathological changes were observed by a light microscope (BX-FM, Olympus Corp, Tokyo, Japan).30 The score of the cerebrum injury was according to previously study.31
2.4 | Transmission electron microscopy

Fresh cerebrum tissues of quails were cut into small pieces less than 1 mm$^3$ with a sharp blade and fixed in 2.5% glutaraldehyde for 24 h at 4°C. These cerebrum tissues were fixed again with 1% osmic acid and rinsed with 0.1 mol/L phosphate-buffered saline (PBS) before and after fixation. The tissue blocks were dehydrated with different concentrations of ethanol at 4°C. After embedding and curing, the tissue blocks were cut into ultrathin sections. Then they were dyed with uranyl acetate and lead citrate. Finally, the ultrastructure of quail cerebrum was observed by a transmission electron microscope (TEM) Hitachi H-7650 (Tokyo, Japan).

2.5 | Measurement of oxidative stress bio-chemical markers

Quail cerebrum tissues were mixed with PBS buffer and homogenized on ice plate for 2 min with a portable disperser (S10, scientz, Ningbo, China). Then centrifugation was carried out at 3000 r/min for 15 min at 4°C. After centrifugation, the supernatant was used to measure the activity of SOD, and the contents of MDA and GSH in quail cerebrum with the corresponding commercial kits.

2.6 | Measurement of ATP concentration in cerebrum

The ATP content in cerebrum tissue of quail was determined by phosphomolybdic acid colorimetry. The cerebrum tissue was mixed with boiling distilled water to make homogenate. After boiling and centrifugation, the supernatant was taken for testing. According to the manufacturer’s instructions, we added the corresponding reagents. Finally, the absorbance was measured by spectrophotometer (PHILES, 156, Nanjing, China) with the wavelength of 636 nm. The protein concentration of cerebrum tissue was determined by BCA method. The cerebrum tissue of quail was mixed with PBS buffer and homogenized on ice plate for 2 min with a portable disperser (S10, Scientz, Ningbo, China). Then centrifugation was carried out at 3000 r/min for 15 min at 4°C. After centrifugation, the supernatant was used to measure the activity of SOD, and the contents of MDA and GSH in quail cerebrum with the corresponding commercial kits.

2.7 | TUNEL assay

TUNEL assay was used to detect apoptosis. After the quail cerebrum was fixed by perfusion with 4% paraformaldehyde, paraffin sections were prepared routinely, and the section thickness was 4 μm. We performed TUNEL staining according to the manufacturer’s instructions. The sections were treated with 20 μg/mL proteinase K for 15 min at room temperature and then washed two times with PBS. After washing with PBS, the sections were treated with blocking reagent for 30 min at room temperature and washed with PBS for two times. Erasing the water around the samples, the slides were immersed in the TUNEL reaction mixture for 60 min in a dark humid environment at 37°C. After washing slides three times with PBS and erasing the water around the slides, slides were incubated in Converter-POD for 30 min at 37°C, followed by PBS washing. After PBS washing, the DAB solution was used to develop the stain. The samples were incubated at room temperature for 30 min and washed with PBS for three times, then dehydrated, and mounted in neutral resins. Apoptotic cells were stained brown indicating positive cells, and non-apoptotic cells were stained blue indicating negative cells. The cells were examined by a light microscope. The TUNEL index (%) was calculated by dividing the number of TUNEL positive cells by the total number of cells. This index was considered in assessing the apoptotic index of TUNEL-stained cerebrum tissues. Five regions of randomly selected TUNEL stained sections were counted for each sample and the average was calculated.

2.8 | Quantitative real-time PCR

In order to extract total RNA from quail cerebrum tissue, Trizol reagent was used. RNA concentration was determined by using ultramicro nucleic acid protein analyzer (Implen, N60, Germany), then the RNA was reverse transcribed into cDNA by a cDNA reverse transcription kit (Vazyme, Nanjing). As shown in Table 1, specific primers were synthesized by Sangon Biotech (Shanghai, China). The gene was combined with the corresponding primer according to the instructions of the SYBR Green RT-qPCR Superscript kit (Vazyme, Nanjing, China). The levels of relative mRNA were analyzed by the Bio-Rad CFX96 touch (Hercules, CA, USA), 2$^{-\Delta\Delta C_{T}}$ method was used to analysis the data.

2.9 | Western blot analysis

Western blot analysis is a valuable study to measure the expression of protein. The cerebrum tissue of quail was lysed with the lysate composed of PMSF and RIPA, and the total proteins were extracted from the cerebrum tissue, then measured by BCA kit. Before transferring the proteins to PVDF membranes, the proteins should be electrophoresed in 12% gel SDS-PAGE. The membranes were then sealed in the blocking solution for 2 h, followed by overnight incubation at 4°C with the original antibody. Next, TBST was used to wash the membranes, and the membranes were incubated with the appropriate secondary antibody for 40 min at 37°C. Finally, the membranes were washed with TBST again, the protein band strength was quantified by Image Pro-Plus 6.0 software (Rockville, MD, USA).

2.10 | Protein–protein interaction analysis

In order to explore the relationship between target genes, Protein–protein interaction (PPI) network was constructed (http://string-db.org/, Version 11.0). Specifically, we chose “Coturnix japonica” as the organism, and inputted the target genes such as PERK (Eif2ak3), ATF6 (Atf6), IRE1 (Ern1), GRP78 (Hspa5), AIF (Aifm1), Cyt C (Cycs), caspase-3 (Casp3), and Bcl-2 (Bcl2) into the STRING database. And
then constructed PPI network of the selected species with the genes that can be retrieved from the database.

2.11 | Statistical analysis

SPSS 19.0 software (SPSS, Chicago, IL, USA) was used to analyze data. The data were presented as mean ± SEM. One-way ANOVA was performed to compare multiple groups following Dunnett’s post-hoc test. $P < 0.05$ was considered statistically significant.

3 | RESULTS

3.1 | DLM treatment exacerbated cerebrum injury in quail

As shown in Figure 1, the cerebrum tissue structure of the control group was normal, with normal neuronal morphology and diversity. Compared with the control group, the neuronal morphology was changed and some neurons were shrunk in the DLM groups. In addition, some nuclei were disappeared and a large number of diseased neurons appeared in the high dose DLM group.

3.2 | DLM treatment changed neurons ultrastructure in quail cerebrum

To determine the damage of neurons, we used TEM to observe the ultrastructure of quail cerebrum neurons. The normal morphology of nucleus, mitochondria, and ER could be observed in the control group. However, changes in nuclear morphology, mitochondrial swelling, and ER swelling were observed in DLM-treatment groups. In addition, the happening of nuclear lysis, mitochondrial swelling and ridge rupture, and ER swelling occurred significantly in the high dose group compared with the control group (Figure 2).

3.3 | DLM treatment induced oxidative stress and reduced ATP level in quail cerebrum

To analyze the level of oxidative stress in the cerebrum tissues of quails, we detected the concentration of MDA and GSH, and the activity of SOD. As expected, DLM significantly increased the concentration of MDA (Figure 3A). In addition, treatment with DLM significantly decreased GSH concentration and SOD activity compared with the control group (Figure 3B and C). The ATP concentration of quail cerebrum was shown in Figure 3D. Compared with the control group, the ATP concentration of quail cerebrum in DLM-treatment groups decreased significantly and this effect was dose-related.

3.4 | DLM treatment induced neuronal apoptosis in quail cerebrum

Apoptosis of cerebrum neurons in quail was determined by TUNEL staining. There were only a few TUNEL-positive cells in the control group. However, the number of apoptotic cells increased significantly in DLM-treatment groups and it was a dose-dependent relationship. Furthermore, the apoptosis rate of neurons in high dose DLM group was the highest (Figure 4).

3.5 | DLM induced apoptosis via activating the ER pathway and exacerbating the mitochondrial damage pathway in quail cerebrum

The ER pathway and mitochondrial pathway are key cell life activities. The new study provides evidence that the ER and mitochondrial

pathway participate in the process of apoptosis. With the further research, the study has shown that ER pathway and mitochondrial damage pathway are related to upstream related molecules. We measured the ER stress related mRNA expression levels of glucose regulated protein 78 kD (GRP78), ATF6, PERK, and IRE1. The results showed that the expressions of GRP78, ATF6, PERK, and IRE1 in...
DLM groups were increased significantly compared to the control group and showed a dose-dependent relationship (Figure 5D). In the mitochondrial apoptotic pathway, we detected the protein expressions of Bcl-2, Bax, and caspase-3. Furthermore, we measured the mRNA expression levels of AIF, Cyt C, Bcl-2, and caspase-3. In DLM groups, the protein expression levels of Bcl-2 was decreased significantly and the Bax protein was increased (Figure 5A). The protein expression levels of caspase-3 (Figure 5B) was increased significantly in a dose-dependent manner. As shown in Figure 4C, the mRNA expression levels of AIF, Cyt C, and caspase-3 were increased significantly and the mRNA expression levels of Bcl-2 decreased in DLM groups, and this effect was dose-related.

3.6 | PPI analysis

We constructed a PPI analysis network of cerebrum damage using the STRING 10 database (Figure 6) to confirm our conclusion. The
Cerebrum damage dynamic clusters included PERK, ATF6, IRE1, GRP78, AIF, Cyt C, caspase-3, and Bcl-2. The PPI analysis revealed the relationship between cerebrum damage and ER stress, as well as mitochondrial dysfunction.

4 | DISCUSSION

Apoptosis is a process of cells organizing self-destruction. Numerous studies have demonstrated that DLM can cause neuronal apoptosis. In this study, we explored the relationship among quail cerebrum neuronal apoptosis, mitochondrial, and ER. The mitochondrial apoptosis pathway is regulated by the members of the Bcl-2 family including pro-apoptotic (Bax) and anti-apoptotic (Bcl-2 and Bcl-xl) proteins, while ER apoptosis pathway is activated by long-term or serious ER stress. Here, we found that DLM decreased Bcl-2 protein expression and increased the expression of Bax protein, suggesting that DLM promotes neuronal apoptosis of quail cerebrum related with mitochondrial. Indeed, this was confirmed by TUNEL staining of cerebrum tissue from quail. Thus, DLM exposure induces neuronal apoptosis in quail cerebrum.

ER stress pathway is a new type of apoptosis pathway. Exposed to DLM, neurons may undergo ER stress. Severe or long-term ER stress impairs ER function, and then apoptosis will be induced by activating ER stress-mediated apoptosis signaling pathway. At this time, the three activated transmembrane proteins ATF-6, IRE, and PERK will promote the production of C/EBP-homologous protein (CHOP), and then trigger apoptosis. Normally, the three membrane proteins are combined with chaperone GRP78/Bip and keep inactive. However, when ER stress outbreak, ATF-6, IRE, and PERK will be separated from GRP78/Bip and be activated. IRE1 and ATF-6 are transferred into the nucleus and bind to the ER stress response element to initiate the transcription and expression of CHOP. The transcription factor ATF-4 which is the downstream of PERK can bind to the AARE domain of the CHOP and promote CHOP expression, then down-regulate the expression of anti-apoptotic protein Bcl-2. In our experiment, the findings indicated that DLM exposure obviously induced ER stress and further triggered neuronal apoptosis in quail.
Therefore, ER stress gets involved in the progress of DLM-induced apoptosis of quail cerebrum and plays an important role. Mitochondria are the main source of ROS with the production of ATP. The destruction of mitochondria will lead to the accumulation of a large number of ROS, which causes more serious mitochondrial dysfunction. MDA, SOD, and GSH are important indicators for detecting oxidative stress. The release of ROS can cause oxidative stress in cells and it can trigger apoptosis through a variety of signaling pathways. When mitochondria undergo apoptosis, the expression of Bcl-2 will be inhibited. Simultaneously, the permeability of the mitochondrial membrane changes, then AIF and Cyt C are released from the mitochondria into the cytoplasm. AIF can be transported into the nucleus and cause DNA fragmentation. AIF and Cyt C are both pro-apoptotic factors. These factors activate the caspase signaling pathway and undergo a series of enzyme-linked reactions to apoptosis. Our results showed that DLM induced mitochondrial damage of quail cerebrum neurons, causing oxidative stress of neurons. Meanwhile, the expressions of mitochondrial apoptosis-related factors AIF and Cyt C were increased. The TEM and the ATP assay results further confirmed DLM-induced mitochondria dysfunction in quail cerebrum. Hence, mitochondria dysfunction is involved in the process of neuronal apoptosis in quail cerebrum induced by chronic DLM exposure.

The use of pesticides is closely related to human health. DLM is a highly effective insecticide, but with a defect of polluting the environment. As a representative animal of poultry, quail has excellent advantages of high sensitivity, easy to feed, and small size. Besides, the toxic effects of quails are closer to the toxic effects of toxic substances in the natural environment, because of their idiosyncratic genetic conditions. Therefore, quail has high great research value in pesticide safety evaluation. Studies on the effects of DLM neurotoxic have been reported in mammals, fish, and insects. Furthermore, there were only a few studies about the exposure of pyrethroid induced the change of brain morphology. According to report, in mouse cells, DLM can continuously increase the content of Ca$^{2+}$ in cells, and the imbalance of Ca$^{2+}$ homeostasis will promote ER stress. The response of ER stress will produce a large amount of CHOP, which inhibits the expression of Bcl-2 located on the mitochondrial membrane, thereby promoting apoptosis of the mitochondrial pathway. With the gradual loss of ER function, ER will further release Ca$^{2+}$ into the cell cytoplasm. High concentrations of Ca$^{2+}$ can directly act on mitochondria, causing mitochondrial dysfunction and triggering mitochondrial-related apoptosis. However, the effect of DLM on intracellular Ca$^{2+}$ in cells of quail has not been reported to date. The specific mechanism of ER induced by DLM in quails is still unclear. In our study, the results suggest that DLM caused neuronal apoptosis of quail cerebrum. However, the mechanism is still unclear whether neuronal apoptosis of quail is caused by ER stress and mitochondrial dysfunction working together or separately (Figure 7). The genome-wide gene expression profiling could be used to clarify the mechanism in the future. Hence, we speculate that DLM induces neurotoxicity in quail cerebrum neurons, which is similar to DLM-induced cytotoxicity by increasing intracellular Ca$^{2+}$ concentration in other animals.

**CONCLUSION**

In conclusion, DLM exposure induces apoptosis of cerebrum neurons in quails via promoting ER stress and mitochondrial dysfunction. Our study provides a novel explanation for DLM-induced apoptosis of avian cerebrum neurons.
