LINEAR PROGRAMMING FICTITIOUS PLAY ALGORITHM FOR MEAN FIELD GAMES WITH OPTIMAL STOPPING AND ABSORPTION

ROXANA DUMITRESCU¹, MARCOS LEUTSCHER² AND PETER TANKOV²,*

Abstract. We develop the fictitious play algorithm in the context of the linear programming approach for mean field games of optimal stopping and mean field games with regular control and absorption. This algorithm allows to approximate the mean field game population dynamics without computing the value function by solving linear programming problems associated with the distributions of the players still in the game and their stopping times/controls. We show the convergence of the algorithm using the topology of convergence in measure in the space of subprobability measures, which is needed to deal with the lack of continuity of the flows of measures. Numerical examples are provided to illustrate the convergence of the algorithm.

1. INTRODUCTION

The goal of this paper is to develop a numerical algorithm for computing Nash equilibria in mean-field games of optimal stopping and mean-field games with regular control and absorption.

Mean-field games (MFGs) are useful for approximating $N$-player Nash equilibria, which are rarely tractable. They have been introduced at about the same time by Lasry and Lions [39–41] and Huang et al. [30] as limit version of games with a large number of agents, symmetric interactions and negligible individual influence of each player on the others. In the literature, several approaches have been developed to prove existence of an MFG Nash equilibrium. The analytic approach, introduced by Lasry and Lions and Huang, Malhame and Caines, boils down to solving a coupled system of nonlinear partial differential equations: a Hamilton–Jacobi–Bellman equation (backward in time) satisfied by the value function of the representative agent and a Fokker–Planck–Kolmogorov equation (forward in time) describing the evolution of the density of agents when the optimal control is used. The probabilistic approach, introduced by Carmona and Delarue, based on the stochastic maximum principle, reduces the problem to a system of coupled forward-backward stochastic differential equations of McKean–Vlasov type. Finally, the compactification methods consist in relaxing the optimization problems, and often allow to prove existence under weaker assumptions than the first two approaches. We refer here to the controlled

Keywords and phrases. Mean-field games, Optimal stopping, Continuous control, Absorption, Infinite-dimensional linear programming, Fictitious play.

martingale problem approach, introduced in the MFG setting by Lacker \[38\] and the linear programming approach, developed for MFGs of optimal stopping in \[12\] and extended to a more general framework in \[24\]. In the single-agent case the linear programming approach is described in various papers, e.g. \[21, 35, 36\]. A similar approach has been introduced in the works \[42\] (deterministic case) and \[26\] (stochastic case) and in the context of Aubry-Mather theory in the deterministic and stochastic cases (see e.g. \[10, 27, 43, 44\]). In the mean-field game setting, Aubry-Mather theory has been applied in the recent paper \[6\] for studying a price formation MFG model.

Fast numerical methods for computing Nash equilibria are very important for applications. Several algorithms exist in the literature for the case of regular control without absorption. These use either analytic or probabilistic approach and iterate over the value function and the mass distribution (see e.g. \[1, 2, 5, 19\]). Another method, based on the fictitious play algorithm which goes back to Brown \[14\] in the classical setting of game theory, has been introduced in the Mean-field framework in \[18\]. The fictitious play algorithm is a learning procedure, very natural in this setting. Due to the complexity of the game, it is unrealistic to assume that the agents can actually compute the equilibrium configuration. Such a configuration may only arise if the players learn how to play the game. The fictitious play for MFGs has been applied in the settings of potential MFGs with regular controls \[18\] and first order MFGs with regular controls \[25, 28, 29\]. A continuous time version of the fictitious play has been studied in \[47\] for finite MFGs with common noise.

The compactification methods based on the controlled martingale problem approach, although they simplify the proofs of existence, are very abstract and cannot be exploited for the development of numerical algorithms. On the contrary, the linear programming formulation seems appropriate to build numerical schemes, see e.g. \[21, 45\].

In this paper we develop and study the linear programming fictitious play algorithm (LPFP) for mean-field games of optimal stopping and regular control with absorption, in the case of second-order possibly non-potential games, under general assumptions on the coefficients and a non-strict monotonicity condition on the reward function with respect to the measure.

The LPFP algorithm starts with an initial guess of the equilibrium and iterates the following two steps:

(i) Compute the best response corresponding to the guess by solving a linear program.
(ii) Update the guess via a convex combination (with well chosen parameters) of the previous guess and the best response computed in step (i).

While the linear program is infinite dimensional, one can approximate it by a finite dimensional linear program (see e.g. \[21, 45\]), for which fast and accurate algorithms exist in most computing environments. We provide several numerical examples, which illustrate the convergence of the algorithm.

We emphasize that unlike other algorithms which iterate over both, the value function and the distribution of agents, the LPFP algorithm iterates only over the distribution of agents, which is the main object of interest in the mean-field game setting.

Very few papers present numerical algorithms for Mean-field games of optimal stopping and discuss their convergence. \[12\] prove the convergence of fictitious play for potential games and \[9\] studies the Uzawa algorithm for the (possibly non-potential) MFG system introduced in \[8\] in the stationary case, under the assumption of strict monotonicity of the reward map. This LPFP algorithm has already been used for applications to water management and electricity markets in \[13\] and \[3\], respectively, but no theoretical convergence results have been provided. In the recent paper \[23\], the authors study the class of submodular MFGs. In particular, in the case of optimal stopping, they prove the existence of equilibria using Tarski’s fixed point theorem and provide an approximation of the minimal equilibria (with respect to a specific order structure) by starting with the minimal measure flow and iterating the minimal best response. The results hold under the opposite inequality to the Lasry–Lions monotonicity condition used in this paper. The theory on mean-field games with regular control and absorption has received a lot of interest recently, being developed in \[15–17\], and using the linear programming approach in \[24\]. To the best of our knowledge, no algorithm has been proposed so far in this setting and one of our goals is to fill this gap.
One of the principal difficulties of MFGs with stopping/absorption is that the standard weak convergence topology for measures cannot be used due to the possible lack of regularity of the flow of measures. In this paper, we solve this problem and provide general convergence results for LPFP, by finding an appropriate topology, i.e. the topology of the convergence in measure in infinite-dimensional spaces and providing appropriate estimates using well chosen metrics. Furthermore, the use of this topology allows us to prove the existence of an equilibria in a much more general framework compared to [12] and [24].

The paper is organized as follows. In Section 2, we introduce the LPFP algorithm for MFGs of optimal stopping. We study the compactness under the convergence in measure topology of the set of admissible measures and provide several key estimates, which are used to prove the convergence of the algorithm. Numerical illustrations are provided. In Section 3, we propose an LPFP algorithm in the case of regular control with absorption, and provide several key estimates, which are used to prove the convergence of the algorithm. In Appendixes A and B we give some technical results and some examples of sufficient conditions under which the main results hold.

**Notation.** For a topological space \((E, \tau)\) we denote by \(\mathcal{B}(E)\) the Borel \(\sigma\)-algebra, by \(\mathcal{M}^s(E)\) the set of Borel finite signed measures on \(E\), by \(\mathcal{M}(E)\) the set of Borel finite positive measures on \(E\), by \(\mathcal{P}^{\text{sub}}(E)\) the set of Borel subprobability measures on \(E\) and by \(\mathcal{P}(E)\) the set of Borel probability measures on \(E\). We denote by \(\mathcal{M}(E)\) the set of Borel measurable functions from \(E\) to \(\mathbb{R}\), by \(\mathcal{M}_b(E)\) the subset of Borel measurable and bounded functions, by \(C(E)\) the subset of continuous functions, and by \(\mathcal{C}_0(E)\) the subset of continuous and bounded functions. The set \(\mathcal{M}_0(E)\) is endowed with the supremum norm \(\|\varphi\|_\infty = \sup_{x \in E} |\varphi(x)|\). If \((E, d)\) is a metric space and \(p \geq 1\), we denote by \(\mathcal{M}_p(E)\) (respectively \(\mathcal{M}_p(E), \mathcal{P}^{\text{sub}}_p(E)\) and \(\mathcal{P}_p(E)\)) the set of \(\mu \in \mathcal{M}(E)\) (respectively \(\mathcal{M}(E), \mathcal{P}^{\text{sub}}(E)\) and \(\mathcal{P}(E)\)) such that there exists a point \(x_0 \in E\) so that \(\int_E d(x, x_0)^p \mu(\mathrm{d}x) < \infty\), where \(\mu\) is the total variation measure of \(\mu\).

Let \(T > 0\) be a terminal time horizon, \(\mathcal{O}\) be an open subset of \(\mathbb{R}\) with closure \(\bar{\mathcal{O}}\) and \(A\) be a compact subset of \(\mathbb{R}\). We denote by \(\mathcal{C}_b^1,2([0, T] \times \bar{\mathcal{O}})\) the set of functions \(u \in C_b([0, T] \times \bar{\mathcal{O}})\) such that \(\partial_t u, \partial_x u, \partial_{xx} u \in C_b([0, T] \times \bar{\mathcal{O}})\). We denote by \(\mathbb{R}_+\) the set \([0, +\infty[\). For a given process \((Y_t)_t\) and a Borel subset \(B\) of \(\mathbb{R}\), we define the random time \(\tau^Y_B(\omega) := \inf\{t \geq 0 : Y_t(\omega) \notin B\}\), with the convention \(\inf\emptyset = +\infty\).

Since we will deal with different topologies and distances throughout the paper, we list them here, making reference to the places where they are introduced: the topologies \(\mathcal{T}_0\) (weak convergence), \(\mathcal{T}_p\) (weak convergence with \(p\)-growth), \(\bar{\mathcal{T}}\) (stable convergence), \(\bar{\mathcal{T}}_p\) (stable convergence with \(p\)-growth) and the metric \(d_{BL}\) are introduced in Appendix A. The topology \(\bar{\mathcal{T}}_p\) of the convergence in measure for flows of subprobabilities in \(\mathcal{P}^{\text{sub}}_p\) is defined just before Assumption 1. The metric \(W^1_p\) on \(\mathcal{P}^{\text{sub}}_p\) is defined just before Proposition 2.13 and the metrics \(d_M\) and \(\rho\) are defined in Proposition 2.13.

## 2. Linear Programming Algorithm for Optimal Stopping MFGs

### 2.1. Preliminaries and main result

We describe here the LPFP algorithm for MFGs of optimal stopping, i.e. when players choose the time to exit the game. We present the definition of LP (Linear Programming) MFG Nash equilibrium in this setting and prove the convergence of the LPFP algorithm to the LP MFG Nash equilibrium.

**Preliminaries.** Let \(U\) be the set of flows of measures on \(\bar{\mathcal{O}}\), \((m_t)_{t \in [0, T]}\), such that: for every \(t \in [0, T]\), \(m_t\) is a Borel finite signed measure on \(\mathcal{O}\), for every \(B \in \mathcal{B}(\mathcal{O})\), the mapping \(t \mapsto m_t(B)\) is measurable, and \(\int_0^T m_t(\partial \mathcal{O}) \mathrm{d}t < \infty\), where \(|m_t|\) is the total variation measure of \(m_t\).

We define \(\hat{U}\) as the quotient space given by \(U\) and the almost everywhere equivalence relation on \([0, T]\), that is, if \(dt\)-almost everywhere on \([0, T]\) the measures \(m_t^1\) and \(m_t^2\) coincide, the measure flows \((m_t^1)_{t \in [0, T]}\) and \((m_t^2)_{t \in [0, T]}\) are considered equivalent. \(\hat{U}\) endowed with the usual sum and scalar multiplication is a vector space, where the zero vector is given by the family of null measures \((0)_{t \in [0, T]}\). To each \((m_t)_{t \in [0, T]}\) in \(\hat{U}\) we associate a Borel finite signed measure on \([0, T] \times \bar{\mathcal{O}}\) defined by \(m_t(dx) \mathrm{d}t\) and we endow \(\hat{U}\) with the topology of weak
convergence of the associated measures. For $p \geq 1$, define the subsets of $\bar{U}$,
\[
\bar{U}_p := \left\{ m \in \bar{U} : \int_0^T \int_{\mathcal{O}} |x|^p m_l(dx)dt < \infty \right\},
\]
endowed with the weak topology with respect to continuous functions with $p$-growth, denoted by $\tau_p$, of the associated measures (see Appendix A). We denote by $V$ (resp. $V_p$) the set of measure flows $(m_t)_{t \in [0,T]} \in \bar{U}$ (resp. $\bar{U}_p$) such that $dt$-a.e. $m_t$ is a subprobability measure. We make the convention that when integrating a quantity with respect to $dt$, the version taken for $(m_t)_{t \in [0,T]} \in V$ inside the integral is such that, for each $t \in [0,T]$, $m_t$ is a subprobability measure. We note that $\bar{U}$ is a Hausdorff locally convex topological vector space and $V_p$ is metrizable. We endow the set $\mathcal{P}_p([0,T] \times \mathcal{O})$ with the topology $\tau_p$ and we will often work on the product space $\mathcal{P}_p([0,T] \times \mathcal{O}) \times V_p$ endowed with the product topology, which we will denote $\tau_p \otimes \tau_p$. Since this product space is metrizable, we will often work with sequences. Finally, consider the set $M_p := M([0,T]; \mathcal{P}^{\text{sub}}(\mathcal{O}))$ of Borel measurable functions from $[0,T]$ to $\mathcal{P}^{\text{sub}}(\mathcal{O})$ identified a.e. on $[0,T]$. This set is endowed with the topology of convergence in measure (see Appendix B) which is denoted by $\bar{\tau}_p$. Moreover, any $m \in V_p$ admits a representative in $M_p$. We can thus consider, without loss of generality, the topology $\bar{\tau}_p$ in $V_p$.

We are given constants $q > p \geq 1 \lor r$, where $r \in [0,2]$ and $q \geq 2$, and the following functions:
\[
(b, \sigma) : [0, T] \times \mathbb{R} \to \mathbb{R}, \quad f : [0, T] \times \mathcal{O} \times \mathcal{P}^{\text{sub}}(\mathcal{O}) \to \mathbb{R}, \quad g : [0, T] \times \mathcal{O} \times \mathcal{P}_p([0,T] \times \mathcal{O}) \to \mathbb{R}.
\]
The sets $[0,T]$, $\mathbb{R}$, and $\mathcal{O}$ are endowed with the usual topology and the sets $\mathcal{P}^{\text{sub}}(\mathcal{O})$ and $\mathcal{P}_p([0,T] \times \mathcal{O})$ are endowed with the topology $\tau_p$. Throughout the paper, we will adopt the bilinear form notation
\[
\langle f(m), m' \rangle := \int_0^T \int_{\mathcal{O}} f(t, x, m_t)m'_l(dx)dt, \quad \langle g(\mu), \mu' \rangle := \int_{[0,T] \times \mathcal{O}} g(t, x, \mu')d(\mu(dx, dt)),
\]
where $(\mu, m), (\mu', m') \in \mathcal{P}_p([0,T] \times \mathcal{O}) \times V_p$.

In this section, we let the following assumptions hold true.

**Assumption 1.**

1. $m_0^\sigma \in \mathcal{P}_Q(\mathcal{O})$.
2. The functions $(t, x) \mapsto b(t,x)$ and $(t, x) \mapsto \sigma(t, x)$ are jointly measurable and continuous in $x$ for each $t$. Moreover, there exists a constant $c_1 > 0$ such that for all $(t, x, y) \in [0,T] \times \mathbb{R} \times \mathbb{R}$,
   \[
   |b(t, x) - b(t, y)| + |\sigma(t, x) - \sigma(t, y)| \leq c_1|x - y|, \quad |b(t, x)| \leq c_1[1 + |x|], \quad \sigma^2(t, x) \leq c_1[1 + |x|^r].
   \]
3. The function $(t, x, m) \mapsto f(t, x, m)$ is jointly measurable and continuous in $(x,m)$ for each $t$. The function $g$ is jointly continuous. Moreover, there exists a constant $c_2 > 0$ such that for all $(t, x, m, \mu) \in [0,T] \times \mathcal{O} \times \mathcal{P}^{\text{sub}}(\mathcal{O}) \times \mathcal{P}_p([0,T] \times \mathcal{O})$,
   \[
   |f(t, x, m)| \leq c_2 \left[ 1 + |x|^p + \int_{\mathcal{O}} |z|^p m(dz) \right], \quad |g(t, x, \mu)| \leq c_2 \left[ 1 + |x|^p + \int_{[0,T] \times \mathcal{O}} |z|^p \mu(ds, dz) \right].
   \]
4. One of the following statements is true:
   (a) Unattainable boundary: $b$, $\sigma$ and $\mathcal{O}$ are such that, $\mathcal{P}(\tau^X_\mathcal{O} \geq T) = 1$ where $X$ is the unique strong solution of
      \[
      dX_t = b(t, X_t)dt + \sigma(t, X_t)dW_t, \quad \mathbb{P} \circ X_0^{-1} = m_0^\sigma.
      \]
   (b) Attainable boundary: $\mathcal{O}$ is a bounded open interval and for all $(t, x) \in [0,T] \times \mathbb{R}$, $\sigma^2(t, x) \geq c_\sigma$ for some $c_\sigma > 0$. 

We now give the formulation of the linear programming Optimal Stopping MFG problem, where the set of occupation measures induced by stopping times is replaced by the set of measures satisfying an infinite-dimensional linear constraint. This allows to compactify and convexify the optimization problem. As will be explained later in the paper, the flow of subprobability measures \( m \) is not necessarily regular in time. Because of this lack of regularity, MFGs of optimal stopping require a different treatment, and in particular, a different topology than classical MFGs (stochastic control without absorption). For the strong formulation of Optimal Stopping MFG, we refer the reader to \([24]\).

The relaxed MFG problem: the linear programming formulation.

**Definition 2.1.** Let \( \mathcal{R} \) be the set of pairs \((\mu, m) \in \mathcal{P}_p([0,T] \times \overline{\mathcal{O}}) \times V_p\), such that for all \( u \in C^1_b([0,T] \times \overline{\mathcal{O}})\),

\[
\int_{[0,T] \times \overline{\mathcal{O}}} u(t,x) \mu(dt,dx) = \int_{\overline{\mathcal{O}}} u(0,x) m_0^\mu(dx) + \int_0^T \int_{\overline{\mathcal{O}}} (\partial_t u + \mathcal{L} u)(t,x)m_t(dx)dt,
\]

where \( \mathcal{L} u := b(t,x) \partial_x u(t,x) + \frac{\sigma^2(t,x)}{2} \partial_{xx} u(t,x) \).

**Definition 2.2 (LP formulation of the MFG problem).** For \((\bar{\mu}, \bar{m}) \in \mathcal{P}_p([0,T] \times \overline{\mathcal{O}}) \times V_p\), let \( \Gamma[\bar{\mu}, \bar{m}] : \mathcal{P}_p([0,T] \times \overline{\mathcal{O}}) \times V_p \to \mathbb{R} \) be the reward functional associated to \((\bar{\mu}, \bar{m})\), defined by

\[
\Gamma[\bar{\mu}, \bar{m}](\mu, m) = \langle f(\bar{m}), m \rangle + \langle g(\bar{\mu}), \mu \rangle.
\]

We say that \((\mu^*, m^*) \in \mathcal{P}_p([0,T] \times \overline{\mathcal{O}}) \times V_p\) is an LP MFG Nash equilibrium if \((\mu^*, m^*) \in \mathcal{R}\) and for all \((\mu, m) \in \mathcal{R}\), \( \Gamma[\mu^*, m^*](\mu, m) \leq \Gamma[\mu^*, m^*](\mu^*, m^*) \).

For a finite number of iterations, the LPFP algorithm will produce what we call an \( \varepsilon \)-LP MFG Nash equilibrium.

**Definition 2.3.** For a given \( \varepsilon \geq 0\), we say that \((\mu^*, m^*) \in \mathcal{P}_p([0,T] \times \overline{\mathcal{O}}) \times V_p\) is an \( \varepsilon \)-LP MFG Nash equilibrium if \((\mu^*, m^*) \in \mathcal{R}\) and for all \((\mu, m) \in \mathcal{R}\), \( \Gamma[\mu^*, m^*](\mu, m) - \varepsilon \leq \Gamma[\mu^*, m^*](\mu^*, m^*) \).

In the next paragraph, we present the main results of the paper, in particular the linear programming fictitious play algorithm and its convergence.

The linear programming fictitious play algorithm.

In order to show the convergence of the algorithm, we impose the following Assumption.

**Assumption 2.**

1. For each \((\bar{\mu}, \bar{m}) \in \mathcal{R}\), there exists a unique maximizer of \( \Gamma[\bar{\mu}, \bar{m}] \) on \( \mathcal{R} \).
2. The Lasry–Lions monotonicity condition holds: for all \((\mu, m)\) and \((\bar{\mu}, \bar{m})\) in \( \mathcal{P}_p([0,T] \times \overline{\mathcal{O}}) \times V_p\),

\[
\langle f(\bar{m}) - f(m), m - \bar{m} \rangle + \langle g(\mu) - g(\bar{\mu}), \mu - \bar{\mu} \rangle \leq 0.
\]

3. There exist constants \( c_f \geq 0 \) and \( c_g \geq 0 \) such that for all \( t \in [0,T] \), \( x, x' \in \overline{\mathcal{O}} \), \( m, m' \in \mathcal{P}^{\text{sub}}(\overline{\mathcal{O}}) \), \( \mu, \mu' \in \mathcal{P}_p([0,T] \times \overline{\mathcal{O}}) \),

\[
\begin{align*}
|f(t,x,m) - f(t,x,m')| &\leq c_f(1 + |x|) \int_{\overline{\mathcal{O}}} (1 + |z|^p)|m - m'|(dz), \\
|f(t,x,m) - f(t,x,m') - f(t,x',m) + f(t,x',m')| &\leq c_f|x - x'| \int_{\overline{\mathcal{O}}} (1 + |z|^p)|m - m'|(dz), \\
|g(t,x,\mu) - g(t,x,\mu')| &\leq c_g(1 + |x|) \int_{[0,T] \times \overline{\mathcal{O}}} (1 + |z|^p)|\mu - \mu'|((ds,dz), \\
|g(t,x,\mu) - g(t,x,\mu')| &\leq c_g(|t - t'| + |x - x'|) \int_{[0,T] \times \overline{\mathcal{O}}} (1 + |z|^p)|\mu - \mu'|((ds,dz).
\end{align*}
\]
For sufficient conditions on the coefficients under which the above assumptions hold, the reader is referred to Appendix D.

Note that under Assumption 2, the function \( \Theta : \mathcal{R} \rightarrow \mathcal{R} \) defined by
\[
\Theta(\mu, m) = \arg\max_{(\mu, m) \in \mathcal{R}} \Gamma[\mu, m](\mu, m), \quad (\mu, m) \in \mathcal{R}
\]
is well defined. Furthermore, we can show the uniqueness of the LP MFG Nash equilibrium.

**Proposition 2.4 (Uniqueness of the equilibrium).** Under Assumptions 1 and 2, there exists at most one LP MFG Nash equilibrium.

**Proof.** Let \((\mu, m) \in \mathcal{R}\) and \((\mu', m') \in \mathcal{R}\) be two LP MFG Nash equilibria. Using the equilibrium property we get the following two inequalities:
\[
\langle f(m), m - m' \rangle + \langle g(\mu), \mu - \mu' \rangle \geq 0, \quad \langle f(m'), m' - m \rangle + \langle g(\mu'), \mu - \mu' \rangle \geq 0.
\]
Adding up these two inequalities we obtain \(\langle f(m) - f(m'), m - m' \rangle + \langle g(\mu) - g(\mu'), \mu - \mu' \rangle \geq 0\). By the Lasry–Lions monotonicity condition we get the equality in the previous inequalities. Using that
\[
\Gamma[\mu, m](\mu, m) = \langle f(m), m \rangle + \langle g(\mu), \mu \rangle = \langle f(m), m' \rangle + \langle g(\mu), \mu' \rangle = \Gamma[\mu, m](\mu', m'),
\]
we deduce by the uniqueness of the best response to \((\mu, m)\) that \((\mu, m) = (\mu', m')\).

We propose the following algorithm for computing the LP MFG Nash equilibrium.

**Algorithm 1: LPFP algorithm (Optimal stopping MFGs)**

**Data:** A number of steps \(N\) for the equilibrium approximation; a pair \((\mu^{(0)}, m^{(0)}) \in \mathcal{R}\);

**Result:** Approximate LP MFG Nash equilibrium

1. for \(\ell = 0, 1, \ldots, N - 1\) do
2. Compute a linear programming best response \((\mu^{(\ell + 1)}, m^{(\ell + 1)})\) to \((\mu^{(\ell)}, m^{(\ell)})\) by solving the linear programming problem
\[
\arg\max_{(\mu, m) \in \mathcal{R}} \Gamma[\mu^{(\ell)}, m^{(\ell)}](\mu, m).
\]
3. Set \((\bar{\mu}^{(\ell + 1)}, \bar{m}^{(\ell + 1)}) := \frac{\ell}{\ell + 1}(\mu^{(\ell)}, m^{(\ell)}) + \frac{1}{\ell + 1}(\mu^{(\ell + 1)}, m^{(\ell + 1)}) = \frac{1}{\ell + 1} \sum_{v=1}^{\ell + 1} (\mu^{(v)}, m^{(v)})
4. end

We state now the main theorem. Its proof is provided in Section 2.3.2.

**Theorem 2.5 (Convergence of the algorithm).** Let Assumptions 1 and 2 hold true and consider the sequences \((\mu^{(N)}, m^{(N)})_{N \geq 1}\) and \((\bar{\mu}^{(N)}, \bar{m}^{(N)})_{N \geq 1}\) generated by the Algorithm 1. Then both sequences converge in the product topology \(\tau_p \otimes \bar{\tau}_p\) to the unique LP MFG Nash equilibrium.

**Numerical example.** To illustrate the convergence of the algorithm, we solve numerically a simple MFG of optimal stopping. In this game, the state of the representative player belongs to the domain \([0, T] \times \mathcal{O}\) with \(T = 1\) and \(\mathcal{O} = \mathbb{R}\) and is given by
\[
X_t = X_0 + t + W_t,
\]
i.e. \(b(t, x) = \sigma(t, x) = 1\). The initial states of the players are distributed according to the law \(m_0 = \mathcal{N}(0, 4)\). Before exiting the game, at each time \(t\), the representative player receives an instantaneous reward given by
\[
\int_{\mathbb{R}} (X_t - y)m_t(dy),
\]
where \( m_t \) is the distribution of players still in the game at time \( t \), and upon exiting the game at time \( \tau \), the player receives the terminal reward
\[
\int_{[0,T] \times \mathbb{R}} (\tau - s) \mu(ds,dy),
\]
where \( \mu \) is the joint distribution of exit times and states of the players. The functions \( f \) and \( g \) are therefore defined as follows:
\[
f(t,x,m) := \int_{\mathbb{R}} (x-y)m(dy), \quad g(t,x,\mu) := \int_{[0,T] \times \mathbb{R}} (t - s) \mu(ds,dy).
\]

The representative player has an incentive to stay in the game if its state is higher than the average state of the other players who are still in the game. It is expected that the players starting with a low state value will exit the game immediately, while the players starting with a high state value will stay until the end of the game.

To apply the LPFP algorithm, we discretize the linear program for the computation of the best response as in [21, 45]. More precisely, we consider a time grid \( t_i = i\Delta \) with \( \Delta = \frac{T}{n_t} \), for \( i \in \{0,1,\ldots,n_t\} \) and a state grid \( x_{j+1} = x_j + \delta \), for \( j \in \{0,1,\ldots,n_s - 1\} \) with \( x_0 \in \mathbb{R} \) and \( \delta > 0 \). We define
\[
Lu(t,x) = \frac{\partial u}{\partial t}(t,x) + b(t,x) \frac{\partial u}{\partial x}(t,x) + \frac{\sigma^2}{2}(t,x) \frac{\partial^2 u}{\partial x^2}(t,x), \quad \forall u \in D(L) := C_b^{1,2}([0,T] \times \mathbb{R}).
\]

We set \( D(\hat{L}) \) as the functions in \( D(L) = C_b^{1,2}([0,T] \times \mathbb{R}) \) restricted to the time-state discretization grid. For \( u \in D(\hat{L}) \), we discretize the derivatives as follows
\[
\hat{L}_t u(t_i, x_j) = \frac{1}{\Delta} [u(t_{i+1}, x_j) - u(t_is, x_j)],
\]
\[
\hat{L}_x u(t_i, x_j) = \frac{1}{\delta} \max(b(t_i, x_j),0)[u(t_{i+1}, x_{j+1}) - u(t_{i+1}, x_{j})],
\]
\[
\hat{L}_d u(t_i, x_j) = \frac{1}{\delta} \min(b(t_i, x_j),0)[u(t_{i+1}, x_{j-1}) - u(t_{i+1}, x_{j})],
\]
\[
\hat{L}_{xx} u(t_i, x_j) = \frac{1}{\delta^2} \frac{\sigma^2}{2}(t_i, x_j)[u(t_{i+1}, x_{j+1}) + u(t_{i+1}, x_{j-1}) - 2u(t_{i+1}, x_{j})].
\]
The discretized generator has the form:
\[
\hat{L} u(t_i, x_j) = \hat{L}_t u(t_i, x_j) + \hat{L}_x u(t_i, x_j) + \hat{L}_d u(t_i, x_j) + \hat{L}_{xx} u(t_i, x_j).
\]
The constraint reads as
\[
\sum_{i=0}^{n_t} \sum_{j=0}^{n_s} u(t_i, x_j) \mu(t_i, x_j) - \Delta \sum_{i=0}^{n_t-1} \sum_{j=0}^{n_s-1} \hat{L} u(t_i, x_j) m(t_i, x_j) = \sum_{j=0}^{n_s-1} u(t_0, x_j) m^*_0(x_j),
\]
for \( u \in D(\hat{L}) \). The set \( D(\hat{L}) \) is equal to the linear span of the indicators functions
\[
1_{\{(t_i, x_j)\}}, \quad i \in \{0,1,\ldots,n_t\}, \quad j \in \{0,1,\ldots,n_s\}
\]
on the time-state grid. By linearity, it suffices to evaluate the constraint on the set of indicator functions. We obtain a total number of \( (n_t + 1) \times (n_s + 1) \) constraints. The discretized reward associated to a discrete mean-field term \((\hat{\mu}, \hat{m})\) is given by
\[
\sum_{i=0}^{n_t} \sum_{j=0}^{n_s} g(t_i, x_j, \hat{\mu}) \mu(t_i, x_j) + \Delta \times \sum_{i=0}^{n_t-1} \sum_{j=0}^{n_s-1} f(t_i, x_j, \hat{m}(t_i, \cdot)) m(t_i, x_j).
\]
The generator obtained using these approximations is associated to the following Markov chain (see p. 328 in [37]):

\[
\begin{align*}
\mathbb{P}(Y_{t+1} = x_j|Y_t = x_j) &= 1 - \sigma^2(t_i, x_j) \frac{\Delta}{\delta^2} - |b(t_i, x_j)| \frac{\Delta}{\delta}, \\
\mathbb{P}(Y_{t+1} = x_{j+1}|Y_t = x_j) &= \frac{\sigma^2}{2}(t_i, x_j) \frac{\Delta}{\delta^2} + b^+(t_i, x_j) \frac{\Delta}{\delta}, \\
\mathbb{P}(Y_{t+1} = x_{j-1}|Y_t = x_j) &= \frac{\sigma^2}{2}(t_i, x_j) \frac{\Delta}{\delta^2} + b^-(t_i, x_j) \frac{\Delta}{\delta}.
\end{align*}
\]

For this to be well defined, we should have

\[1 - \sigma^2(t_i, x_j) \frac{\Delta}{\delta^2} - |b(t_i, x_j)| \frac{\Delta}{\delta} \geq 0,
\]

meaning that we should have for all \(i\) and \(j\)

\[
\Delta \leq \frac{\delta^2}{\sigma^2(t_i, x_j) + \delta |b(t_i, x_j)|}.
\]

The discretized constraint coincides with the constraint associated to the Markov chain \(Y\) (with absorption on \(\{x_0, x_n\}\)). Convergence of this approximating procedure in the context of single-agent stochastic control is studied in [37, Chapter 10].

These finite dimensional linear programs are solved using the Gurobi\(^1\) solver in Python (Version 9.5.1). In order to evaluate the convergence of the algorithm, we compute the (discrete time-space) exploitability (term borrowed from [47]) at each iteration:

\[
\varepsilon_N = \Delta \sum_{i=0}^{n_1-1} \sum_{j=1}^{n_2-1} f\left(t_i, x_j, \bar{m}^{(N-1)}(t_i, \cdot)\right) \left(m^{(N)}(t_i, x_j) - \bar{m}^{(N-1)}(t_i, x_j)\right)
+ \sum_{i=0}^{n_1} \sum_{j=0}^{n_2} g(t_i, x_j, \bar{\mu}^{(N-1)}) \left(\mu^{(N)}(t_i, x_j) - \bar{\mu}^{(N-1)}(t_i, x_j)\right).
\]

In Figure 1 (left graph), we can observe the evolution of the distribution of the players \(m_t\) over time and Figure 1 (right) shows the exit distribution \(\mu\) of the players. As expected, players starting at a low position exit the game immediately and players starting at higher positions exit the game at later dates. Finally, Figure 2 illustrates the convergence of the algorithm via a log–log plot (base 10) of the exploitability. We can observe that the convergence is in \(O(N^{-1})\).

2.2. Compactness of \(\mathcal{R}\) under the convergence in measure topology

In this subsection, we prepare the ground for showing the convergence of our LPFP algorithm, by providing several results which are needed in the proof of the main result. In particular, we show the compactness of the set \(\mathcal{R}\) under the topology of the convergence in measure. This result also allows to prove the existence of an equilibrium under Assumption 1 only (see Theorem 2.12), improving earlier results in [12] and [24], which did not take into account a general dependence of the map \(f\) on \(m\) (resp. \(g\) on \(\mu\)) nor coefficients with polynomial growth.

Recall that by Theorem C.6 in [24], for \((\mu, m) \in \mathcal{R}\), there exists \((\Omega, \mathcal{F}, \mathbb{F}, \mathbb{P}, W, \tau, X)\), such that \((\Omega, \mathcal{F}, \mathbb{F}, \mathbb{P})\) is a filtered probability space, \(W\) is an \(\mathbb{F}\)-Brownian motion, \(\tau\) is an \(\mathbb{F}\)-stopping time such that \(\tau \leq T \wedge \tau^X\) \(\mathbb{P}\text{-a.s.}\) and \(X\) is an \(\mathbb{F}\)-adapted process verifying

\[
X_t = X_0 + \int_0^t b(s, X_s)ds + \int_0^t \sigma(s, X_s)dW_s, \quad \mathbb{P} \circ X_0^{-1} = m_0^*,
\]

\(^1\)https://www.gurobi.com/.
\( \mu = \mathbb{P} \circ (\tau, X_\tau)^{-1}, \) and \( m_t(B) = m^*_t(B), \) \( B \in \mathcal{B}(\bar{\mathcal{O}}), \) \( t - a.e, \)

where

\[
m^*_t(B) := \mathbb{E}^P[\mathbb{1}_B(X_t)\mathbb{1}_{t<\tau}].
\]

Seen as a mapping from \([0, T]\) to \( \mathcal{P}_{sub}(\bar{\mathcal{O}})\) endowed with the topology of weak convergence, \( m^* \) is càdlàg. In fact, for any \( \varphi \in C_b(\bar{\mathcal{O}}) \) and \( t_n \downarrow t, \) by dominated convergence,

\[
\lim_{n \to \infty} \int_{\bar{\mathcal{O}}} \varphi(x)m^*_{t_n}(dx) = \lim_{n \to \infty} \mathbb{E}^P[\varphi(X_{t_n})\mathbb{1}_{t_n<\tau}] = \mathbb{E}^P[\varphi(X_t)\mathbb{1}_{t<\tau}] = \int_{\bar{\mathcal{O}}} \varphi(x)m^*_t(dx).
\]

Similarly, for \( t_n \uparrow t, \)

\[
\lim_{n \to \infty} \int_{\bar{\mathcal{O}}} \varphi(x)m^*_{t_n}(dx) = \mathbb{E}^P[\varphi(X_t)\mathbb{1}_{t\leq\tau}].
\]

In general we can not expect the measure \( m^* \) to be continuous (consider for example the measures associated to deterministic stopping times). The MFG interpretation of this time irregularity comes from the possible simultaneous exit of a significant amount of players. Without loss of generality, we can and will always consider the càdlàg representative of \( m, \) still denoted by \( m.\)

The following estimates will be useful to establish the main result of the subsection, Theorem 2.10.
Lemma 2.6 (Estimates). There exist constants $C_1$ and $C_2$ such that for all $(\mu, m) \in \mathcal{R}$ we have the following estimates:

1. For all $t \in [0, T]$, \[ \int_{[0,T] \times \mathcal{O}} |x|^q \mu(dt, dx) \leq C_1, \quad \int_{\mathcal{O}} |x|^q m_t(dx) \leq C_1. \]

2. For all $h \in [0, T]$, we have \[ \int_0^{T-h} d_{BL}(m_{t+h}, m_t)dt \leq C_2 \sqrt{h}, \] where $d_{BL}$ is the bounded Lipschitz distance (see Appendix A).

Proof. Let $(\mu, m) \in \mathcal{R}$ and consider their probabilistic representation. Using standard estimates, we obtain the existence of a constant $C_1 \geq 0$ such that $\mathbb{E}^\|X\|^q_T \leq C_1$. We deduce that

\[ \int_{[0,T] \times \mathcal{O}} |x|^q \mu(dt, dx) = \mathbb{E}^\|X_T\|^q \leq \mathbb{E}^\|X_T\|^q \leq C_1, \]

\[ \int_{\mathcal{O}} |x|^q m_t(dx) = \mathbb{E}^{\|X_t\|^q} \leq \mathbb{E}^{\|X_t\|^q} \leq C_1, \quad t \in [0, T]. \]

Let us show the second estimate. For $\phi \in \text{BL}(\mathcal{O})$ such that $\|\phi\|_{\text{BL}} \leq 1$ (where $\|\cdot\|_{\text{BL}}$ denotes the bounded Lipschitz norm, see Appendix A), $h \in [0, T]$ and $t \in [0, T-h]$, we have:

\[ \int_\mathcal{O} \phi(x)(m_{t+h} - m_t)(dx) = \mathbb{E}^\phi(X_{t+h} \mathbf{1}_{t+h < \tau} - \phi(X_t) \mathbf{1}_{t < \tau}) = \mathbb{E}^\phi((\phi(X_{t+h}) - \phi(X_t)) \mathbf{1}_{t+h < \tau}) = \mathbb{E}^\phi(\phi(X_{t+h}) - \phi(X_t) \mathbf{1}_{t+h < \tau}) = \mathbb{E}^\phi(\phi(X_{t+h}) - \phi(X_t)) \mathbf{1}_{t+h < \tau} - \phi(X_t) \mathbf{1}_{t < \tau}) \leq \mathbb{E}^\phi(\|X_{t+h} - \phi(X_t)\| \mathbf{1}_{t+h < \tau}) \leq \mathbb{E}^\phi(\|X_{t+h} - X_t\|) + \mathbb{E}^\phi(\|\phi(X_t)\| \mathbf{1}_{t < \tau}) \leq \mathbb{E}^\phi(\|X_{t+h} - X_t\|) + \mathbb{E}^\phi(\|\phi(X_t)\| \mathbf{1}_{t < \tau}) \leq \mathbb{E}^\phi(\|X_{t+h} - X_t\|) + \mathbb{E}^\phi(\|\phi(X_t)\| \mathbf{1}_{t < \tau}). \]

Taking the supremum over $\phi$ we get $d_{BL}(m_{t+h}, m_t) \leq \mathbb{E}^\|X_{t+h} - X_t\|) + \mathbb{E}^\|\phi(X_t)\| \mathbf{1}_{t < \tau} \leq C_2$. We also have

\[ \int_0^{T-h} \mathbb{E}^\|X_{t+h} - X_t\| dt \leq \mathbb{E}^\|X_{t+h} - X_t\|) \leq 0 \vee (T-h) \leq h. \]

On the other hand, applying Jensen’s inequality and Burkholder–Davis–Gundy inequality, we get $\mathbb{E}^\|X_{t+h} - X_t\|^2 \leq Ch$, for some constant $C \geq 0$. We deduce that there exists a constant $C_2$ such that $\int_0^{T-h} d_{BL}(m_{t+h}, m_t)dt \leq C_2 \sqrt{h}$. \qed

Using the above estimates, one can show that for $(\mu, m) \in \mathcal{R}$ the flow of measures $m$ is càdlàg as a map from $[0, T]$ to $\mathcal{P}^{\text{sub}}_{\text{loc}}(\mathcal{O})$ endowed with the $\tau$-topology (weak convergence with $p$-growth). In particular $m$ is Borel measurable from $[0, T]$ to $\mathcal{P}^{\text{sub}}_{\text{loc}}(\mathcal{O})$.

Now we study the topology of convergence in measure which is convenient since we will be able to extract subsequences converging in $\mathcal{P}^{\text{sub}}_{\text{loc}}(\mathcal{O})$ a.e. on $[0, T]$. This topology allows to have a general mean-field dependence on the reward function $f$, which was not the case in [24]. Moreover, it permits to consider test functions which are only measurable in time, and therefore to use the topology of the stable convergence. More precisely, we say that $(m^n)_{n \geq 1} \subset V_p$ converges in $\tau_p$ to $m \in V_p$ if for all test functions $\phi : [0, T] \times \mathcal{O} \to \mathbb{R}$ jointly measurable, continuous in $x$ for each $t$ and with $p$-polynomial growth, we have

\[ \lim_{n \to \infty} \int_0^T \int_{\mathcal{O}} \phi(t, x)m^n_t(dx)dt = \int_0^T \int_{\mathcal{O}} \phi(t, x)m_t(dx)dt. \]

We state this result in the next lemma, whose proof follows by Proposition A.7 and an intermediary application of Corollary 2.9 in [32].

Lemma 2.7 (Stable convergence with polynomial growth). On the set $\mathcal{R}$ we have the inclusion $\tau_p \otimes \tau_p \subset \tau_p \otimes \tau_p$. In other words, the convergence in measure of the flow of measures implies the convergence in the stable topology.
For the sake of clarity, we give the definition of a coercive normal integrand, which can be found in [49].

**Definition 2.8** (Coercive normal integrands). \( H : [0,T] \times E \to [0,\infty] \) is a coercive normal integrand if

1. It is measurable with respect to \( \mathcal{L} \otimes \mathcal{B}(E) \), where \( \mathcal{L} \) denotes the Lebesgue-measurable subsets of \([0,T]\).
2. The maps \( x \mapsto H_t(x) := H(t,x) \) are lower semicontinuous for a.e. \( t \in [0,T] \).
3. The sets \( \{ x \in E : H_t(x) \leq c \} \) are compact for any \( c \geq 0 \) and for a.e. \( t \in [0,T] \).

**Lemma 2.9.** The map \( H : \mathcal{P}_{\text{sub}}(\mathcal{O}) \to [0,\infty] \) defined by \( H(m) = \int_{\mathcal{O}} |x|^q m(dx) \), \( m \in \mathcal{P}_{\text{sub}}(\mathcal{O}) \), is a coercive normal integrand, where \( \mathcal{P}_{\text{sub}}(\mathcal{O}) \) is endowed with the topology of weak convergence.

**Proof.** To show that \( H \) is a coercive normal integrand it suffices to prove that \( H \) is measurable and has compact level sets. Define the maps \( H_k(m) = \int_{\mathcal{O}} |x|^q \wedge k m(dx) \), \( k \geq 1 \). These functions are continuous for the topology of weak convergence. Moreover by the monotone convergence theorem \( H_k(m) \) converges to \( H(m) \) for each \( m \in \mathcal{P}_{\text{sub}}(\mathcal{O}) \) as \( k \to \infty \), which allows to conclude the measurability of \( H \). Let us show that \( H \) has compact level sets. Let \( c \geq 0 \) and \( L_c := \{ m \in \mathcal{P}_{\text{sub}}(\mathcal{O}) : H(m) \leq c \} \). By definition

\[
\sup_{m \in L_c} \int_{\mathcal{O}} |x|^q m(dx) \leq c,
\]

which shows that \( L_c \) is relatively compact in \( \mathcal{P}_{\text{sub}}(\mathcal{O}) \). It remains to show that \( L_c \) is closed. Let \( (m^n)_{n \geq 1} \subset L_c \) converging to some \( m \in \mathcal{P}_{\text{sub}}(\mathcal{O}) \). We have for each \( n \geq 1 \) and \( k \geq 1 \), \( H_k(m^n) \leq H(m^n) \leq c \), and taking the limit \( n \to \infty \), we get \( H_k(m) \leq c \). By the monotone convergence theorem we deduce that \( m \in L_c \). \( \square \)

**Theorem 2.10** (Compactness of \( \mathcal{R} \) in \( \tau_p \otimes \tilde{\tau}_p \). The topological space \( (\mathcal{R}, \tau_p \otimes \tilde{\tau}_p) \) is compact.

**Proof.** Since the space \( (\mathcal{R}, \tau_p \otimes \tilde{\tau}_p) \) is metrizable, it suffices to show that it is sequentially compact. Consider a sequence \( (\mu^n, m^n)_{n \geq 1} \subset \mathcal{R} \). Using the estimate (1) from Lemma 2.6

\[
\int_{[0,T] \times \mathcal{O}} |x|^q \mu^n(dt, dx) \leq C_1,
\]

we get by Corollary A.4 that up to a subsequence, \( (\mu^n)_{n \geq 1} \) converges to some \( \mu \in \mathcal{P}_p([0,T] \times \mathcal{O}) \) in \( \tau_p \). Let us show now that we can extract a further subsequence such that \( (m^n)_{n \geq 1} \) converges to some \( m \) in \( \tilde{\tau}_p \). To prove this, we use the relative compactness criterion given in Theorem 2 and Extension 1 in [49] for the convergence in measure topology. Let \( H \) be the map defined in Lemma 2.9. Using the first estimates of Lemma 2.6,

\[
\sup_{n \geq 1} \int_0^T H(m^n_t) dt = \sup_{n \geq 1} \int_0^T \int_{\mathcal{O}} |x|^q m^n_t(dx) dt \leq C_1 T.
\]

Now, using the second estimate of Lemma 2.6, \( \lim_{h \to 0} \sup_{n \geq 1} \int_0^{T-h} d_{BL}(m^n_{t+h}, m^n_t) dt = 0 \). By Theorem 2 and Extension 1 in [49], up to a subsequence, \( (m^n)_{n \geq 1} \) converges to some \( m \in M([0,T]; \mathcal{P}_{\text{sub}}(\mathcal{O})) \) in measure. Up to another subsequence, \( (m^n_t)_{n \geq 1} \) converges weakly to \( m_t \) \( t \)-a.e. on \([0,T]\). Since for each \( t \in [0,T] \),

\[
\sup_{n \geq 1} \int_{\mathcal{O}} |x|^q m^n_t(dx) \leq C_1,
\]

\( (m^n_t)_{n \geq 1} \) converges to \( m_t \) \( t \)-a.e. on \([0,T]\), and in particular \( (m^n)_{n \geq 1} \) converges to \( m \) in \( \tilde{\tau}_p \). Finally, by Lemma 2.7 we get \( \mu^n \to \mu \) in \( \tilde{\tau}_p \) and we can pass easily to the limit in the constraint to conclude that \( (\mu, m) \in \mathcal{R} \). \( \square \)

Recall that if a set is compact and Hausdorff under two comparable topologies, then both topologies coincide (see [46] Chapter 3, Exercise 1.1(b) p. 168). As a consequence of the above theorem, we get the following result which will be useful to consider different metrics on the space \( \mathcal{R} \) in order to show the convergence of the algorithm.
Corollary 2.11. On the set $\mathcal{R}$ the topologies $\tau_0 \otimes \tau_0$, $\tau_p \otimes \tau_p$, $\tau_p \otimes \tilde{\tau}_p$ and $\tau_p \otimes \overline{\tau}_p$ coincide.

The existence of a maximizer of the best response map $\Theta : \mathcal{R} \to 2^\mathcal{R}$ defined by

$$\Theta(\hat{\mu}, \hat{m}) = \arg \max_{(\mu, m) \in \mathcal{R}} \Gamma(\mu, m), \quad (\hat{\mu}, \hat{m}) \in \mathcal{R}$$

follows by the same arguments as in Theorem 2.14 from [24]. Then, by applying the Kakutani–Fan–Glicksberg’s fixed point theorem for set-valued maps (see Theorem 3.11 in [24]) together with an intermediary application of Lemmas F.1 and F.2, we get the existence of an LP MFG equilibrium.

Theorem 2.12 (Existence of LP MFG equilibria). Under Assumption 1, there exists an LP MFG Nash equilibrium.

To show the convergence of the algorithm, we use a precise metric on the set $\mathcal{R}$, denoted by $\rho$, which is introduced below. In particular, this metric is used in Corollary 2.17, where we show the convergence to zero of the distance $\rho$ between two successive best responses. We denote by $W_1$ the 1-Wasserstein metric on $\mathcal{P}_1([0, T] \times \bar{\mathcal{O}})$. We also make use of an analogue of the 1-Wasserstein metric on $\mathcal{P}_1^{\text{sub}}(\bar{\mathcal{O}})$, which is denoted by $W_1'$ and constructed as in Appendix B of [22]. This metric depends on some arbitrary reference point $x_0 \in \bar{\mathcal{O}}$ (which is fixed for the rest of the paper) and metrizes the topology $\tau_1$ in $\mathcal{P}_1^{\text{sub}}(\bar{\mathcal{O}})$ described in Appendix A (see Lemma B.2 in [22]). In particular, we use the following Kantorovich duality type result (Lemma B.1 in [22]):

$$W_1'(m, m') = \sup_{\phi \in \text{Lip}_1(\bar{\mathcal{O}}, x_0)} \int_{\bar{\mathcal{O}}} \phi(x)(m - m')(dx) + |m(\bar{\mathcal{O}}) - m'(\bar{\mathcal{O}})|, \quad m, m' \in \mathcal{P}_1^{\text{sub}}(\bar{\mathcal{O}}),$$

where $\text{Lip}_1(\bar{\mathcal{O}}, x_0)$ is the set of all functions $\phi : \bar{\mathcal{O}} \to \mathbb{R}$ with Lipschitz constant smaller or equal to 1 and such that $\phi(x_0) = 0$.

Proposition 2.13 (Metric $\rho$). Any of the topologies on the set $\mathcal{R}$ considered in Corollary 2.11 is induced by the metric $\rho$, given by $\rho((\mu, m), (\mu', m')) = W_1(\mu, \mu') + d_M(m, m')$, with $(\mu, m), (\mu', m') \in \mathcal{R}$, and

$$d_M(m, m') := \int_0^T W_1'(m_t, m'_t) dt.$$  \hspace{1cm} (2.1)

Proof. Let us prove that the metric $\rho$ metrizes the topology $\tau_1 \otimes \tilde{\tau}_1$ on $\mathcal{R}$. To do so, by Lemma B.1, it suffices to show that there exists a constant $C \geq 0$ such that for each $(\mu, m) \in \mathcal{R}$ we have $t$-a.e. on $[0, T]$, $W_1'(m_t, 0) \leq C$, where 0 denotes the null measure on $\overline{\mathcal{O}}$. Let $(\mu, m) \in \mathcal{R}$. By Lemma 2.6, there exists a constant $C \geq 0$ such that for all $t \in [0, T]$ we have

$$\int_{\overline{\mathcal{O}}} |x|m_t(dx) \leq C.$$

We obtain for all $t \in [0, T]$,

$$W_1'(m_t, 0) = \sup_{\phi \in \text{Lip}_1(\overline{\mathcal{O}}, x_0)} \int_{\overline{\mathcal{O}}} \phi(x)m_t(dx) + m_t(\overline{\mathcal{O}}) \leq \int_{\overline{\mathcal{O}}} |x|m_t(dx) + |x_0| + 1 \leq C + |x_0| + 1.$$

□
2.3. Convergence of the algorithm

In this subsection, Assumptions 1 and 2 are in force. We recall the quantities computed by the algorithm: for \( N \geq 0 \),
\[
\left( \mu^{(N+1)}, m^{(N+1)} \right) := \Theta \left( \bar{\mu}^{(N)}, \bar{m}^{(N)} \right),
\]
\[
\left( \bar{\mu}^{(N+1)}, \bar{m}^{(N+1)} \right) := \frac{N}{N+1} \left( \bar{\mu}^{(N)}, \bar{m}^{(N)} \right) + \frac{1}{N+1} \left( \mu^{(N+1)}, m^{(N+1)} \right) = \frac{1}{N+1} \sum_{k=1}^{N+1} \left( \mu^{(k)}, m^{(k)} \right).
\]
Since all these tuples are in \( \mathcal{R} \), the measures \( (m^{(N)})_N \) and \( (\bar{m}^{(N)})_N \) admit càdlàg representatives. Without loss of generality, we consider the càdlàg representatives, for which the same notation is used.

2.3.1. Estimates and regularity of the best response map

Using Lemma 2.6 (i), we get the claimed estimate.

Analogously, \( \bar{\mu}^{(N+1)} - \bar{\mu}^{(N)} = \frac{1}{N+1} \left[ \mu^{(N+1)} - \bar{\mu}^{(N)} \right] \). Let \( \varphi \in \text{Lip}_1([0,T] \times \mathcal{O}) \), i.e. a 1-Lipschitz function. Using Lemma 2.6 (i),
\[
\left\langle \varphi, \bar{\mu}^{(N+1)} \right\rangle - \left\langle \varphi, \bar{\mu}^{(N)} \right\rangle = \frac{1}{N+1} \left\langle \varphi, \mu^{(N+1)} - \bar{\mu}^{(N)} \right\rangle = \frac{1}{N+1} \left\langle \varphi - \varphi(0, x_0), \mu^{(N+1)} - \bar{\mu}^{(N)} \right\rangle \\
\leq \frac{C}{N},
\]
for some constant \( C \geq 0 \) independent from \( N \) and \( \varphi \). Taking the supremum over \( \varphi \) we obtain the result.

Analogously, \( \bar{m}^{(N+1)} - \bar{m}^{(N)} = \frac{1}{N+1} \left[ m^{(N+1)} - \bar{m}^{(N)} \right] \). Let \( \varphi \in \text{Lip}_1(\mathcal{O}, x_0) \), i.e. a 1-Lipschitz function with \( \varphi(x_0) = 0 \). Using again Lemma 2.6 (i), for all \( t \in [0,T] \),
\[
\left\langle \varphi, \bar{m}^{(N+1)}_t \right\rangle - \left\langle \varphi, \bar{m}^{(N)}_t \right\rangle = \frac{1}{N+1} \left\langle \varphi, m^{(N+1)}_t - \bar{m}^{(N)}_t \right\rangle \\
\leq \frac{C}{N},
\]
for some constant \( C \geq 0 \) independent from \( N \), \( \varphi \) and \( t \). Taking the supremum over \( \varphi \) and integrating over \( t \) we get the claimed estimate.
(ii) By Lemma 2.6, we get for all \( t \in [0, T] \):
\[
\int_{\Omega} (1 + |x|^p) |\tilde{m}_t^{(N+1)} - \tilde{m}_t^{(N)}| (dx) \leq \frac{1}{N+1} \int_{\Omega} (1 + |x|^p) \left( m_t^{(N+1)} + \tilde{m}_t^{(N)} \right) (dx) \leq \frac{C}{N}.
\]

Similarly, by Lemma 2.6, we get
\[
\int_{[0,T] \times \bar{\Omega}} (1 + |x|^p) |\tilde{\mu}^{(N+1)}(t) - \tilde{\mu}^{(N)}(t)| (dt, dx) \leq \frac{C}{N}.
\]

We establish below the following estimates on the reward map.

**Lemma 2.15 (Estimates on the reward map).** There exist constants \( C_f \) and \( C_g \) such that for all \( N \geq 1 \)
\[
\left\langle f\left( \tilde{m}^{(N+1)} \right) - f\left( \tilde{m}^{(N)} \right), m^{(N+2)} - m^{(N+1)} \right\rangle \leq \frac{C_f}{N} d_M \left( m^{(N+1)}, m^{(N+2)} \right),
\]
\[
\left\langle g\left( \tilde{\mu}^{(N+1)} \right) - g\left( \tilde{\mu}^{(N)} \right), \mu^{(N+2)} - \mu^{(N+1)} \right\rangle \leq \frac{C_g}{N} W_1 \left( \mu^{(N+1)}, \mu^{(N+2)} \right).
\]

**Proof.** Let us first show that the function \( \varphi_N : [0, T] \times \bar{\Omega} \to \mathbb{R} \) defined by
\[
\varphi_N(t, x) := f\left( t, x, \tilde{m}_t^{(N+1)} \right) - f\left( t, x, \tilde{m}_t^{(N)} \right)
\]
is a \( C/N \)-Lipschitz continuous function in \( t \) uniformly on \( x \), for some constant \( C \geq 0 \). Indeed, by item (3) in Assumption 2 and Lemma 2.14, for each \( t \in [0, T] \) and \( x, x' \in \bar{\Omega} \), we have
\[
|\varphi_N(t, x) - \varphi_N(t, x')| = |f\left( t, x, \tilde{m}_t^{(N+1)} \right) - f\left( t, x, \tilde{m}_t^{(N)} \right) - f\left( t, x', \tilde{m}_t^{(N+1)} \right) + f\left( t, x', \tilde{m}_t^{(N)} \right)|
\leq c_f |x - x'| \int_{\bar{\Omega}} (1 + |z|^p) \left| \tilde{m}_t^{(N+1)} - \tilde{m}_t^{(N)} \right| (dz) \leq \frac{C}{N} |x - x'|.
\]
The same holds for the function \( (t, x) \mapsto \varphi_N(t, x) - \varphi_N(t, x_0) \), which is equal to 0 at \( x_0 \). By definition of \( W_1' \),
\[
W_1\left( m_t^{(N+2)}, m_t^{(N+1)} \right) = \sup_{\phi \in \text{Lip}_1(\bar{\Omega}, x_0)} \int_{\bar{\Omega}} \phi(x) \left( m_t^{(N+2)} - m_t^{(N+1)} \right) (dx) + \left| m_t^{(N+2)}(\bar{\Omega}) - m_t^{(N+1)}(\bar{\Omega}) \right|.
\]
Furthermore, by item (3) from Assumption 2 and Lemma 2.14, we get that for \( t \in [0, T] \),
\[
|\varphi_N(t, x_0)| = \left| f\left( t, x_0, \tilde{m}_t^{(N+1)} \right) - f\left( t, x_0, \tilde{m}_t^{(N)} \right) \right| \leq c_f (1 + |x_0|) \int_{\bar{\Omega}} (1 + |z|^p) \left| \tilde{m}_t^{(N+1)} - \tilde{m}_t^{(N)} \right| (dz) \leq \frac{C'}{N}.
\]
We derive
\[
\left\langle f\left( \tilde{\mu}^{(N+1)} \right) - f\left( \tilde{\mu}^{(N)} \right), m^{(N+2)} - m^{(N+1)} \right\rangle
\leq \frac{C}{N} \int_{[0,T]} W_1\left( m_t^{(N+2)}, m_t^{(N+1)} \right) dt + \frac{C'}{N} \int_{[0,T]} W_1\left( m_t^{(N+2)}, m_t^{(N+1)} \right) dt
\leq \frac{C + C'}{N} d_M \left( m^{(N+2)}, m^{(N+1)} \right),
\]
where the last inequality follows by definition of the metric \( d_M \) given by (2.1).
Let us show the second estimate. To this purpose, we consider the function \( \psi_N : [0,T] \times \bar{O} \to \mathbb{R} \) defined by
\[
\psi_N(t,x) := g\left(t, x, \bar{\mu}^{(N+1)} \right) - g\left(t, x, \mu^{(N)} \right)
\]
and show that it is a \( C''/N \)-Lipschitz continuous function, for some constant \( C'' \geq 0 \). Indeed, by item (3) in Assumption 2 and Lemma 2.14, for each \( t, t' \in [0,T], x, x' \in O \), we have
\[
|\psi_N(t, x) - \psi_N(t', x')| = \left| g\left(t, x, \bar{\mu}^{(N+1)} \right) - g\left(t, x, \mu^{(N)} \right) - g\left(t', x', \bar{\mu}^{(N+1)} \right) + g\left(t', x', \mu^{(N)} \right) \right|
\leq c_g(|t - t'| + |x - x'|) \int_{[0,T] \times \bar{O}} (1 + |z|^p) |\bar{\mu}^{(N+1)} - \mu^{(N)}| \, (ds, dz)
\leq \frac{C''}{N} (|t - t'| + |x - x'|).
\]
By Kantorovich’s duality theorem,
\[
\left\langle g\left(\bar{\mu}^{(N+1)} \right) - g\left(\mu^{(N+1)} \right), \mu^{(N+2)} - \mu^{(N+1)} \right\rangle = \left\langle \psi_N, \mu^{(N+2)} - \mu^{(N+1)} \right\rangle \leq \frac{C''}{N} \mathcal{W}_1 \left( \mu^{(N+2)}, \mu^{(N+1)} \right).
\]

In the following lemma, we prove the continuity of the best response map.

**Lemma 2.16 (Continuity of the best response map).** The function \( \Theta \) is continuous on \( \mathcal{R} \) with respect to all topologies listed in Corollary 2.11.

**Proof.** Let \((\bar{\mu}^n, \bar{m}^n)_{n \geq 1} \subset \mathcal{R} \) be a sequence converging to \((\bar{\mu}, \bar{m}) \in \mathcal{R} \). Define \((\mu^n, m^n) := \Theta(\bar{\mu}^n, \bar{m}^n) \in \mathcal{R} \) and let \((\mu, m) \in \mathcal{R} \) be a cluster point of the sequence \((\mu^n, m^n)_{n \geq 1} \) (which exists since \( \mathcal{R} \) is compact). Up to taking a subsequence, we assume that the entire sequence converges to \((\mu, m) \). Let \((\bar{\mu}, \bar{m}) \in \mathcal{R} \), we have to show that \( \Gamma[\bar{\mu}, \bar{m}] \leq \Gamma[\bar{\mu}, \bar{m}][\mu, m] \). By definition of \( \Theta \), \( \Gamma[\bar{\mu}, \bar{m}] \leq \Gamma[\bar{\mu}, \bar{m}][\mu, m] \). Taking the limit in the above inequality as \( n \to \infty \) (by an intermediary application of Lemmas F.1 and F.2), we obtain \( \Gamma[\bar{\mu}, \bar{m}][\mu, m] \), which, by uniqueness of the best response, shows that \((\mu, m) = \Theta(\bar{\mu}, \bar{m}) \).

Using Lemmas 2.14 and 2.16, we derive the following result.

**Corollary 2.17 (Proximity between two successive best responses).** We have
\[
\lim_{N \to \infty} \mathcal{W}_1 \left( \mu^{(N)}, \mu^{(N+1)} \right) = 0 \quad \text{and} \quad \lim_{N \to \infty} d_M \left( m^{(N)}, m^{(N+1)} \right) = 0.
\]

**Proof.** Recall the metric \( \rho \) on \( \mathcal{R} \) defined in Proposition 2.13. Viewing \( \Theta \) as a function between the metric spaces \((\mathcal{R}, \rho) \) and \((\mathcal{R}, \rho) \), it is uniformly continuous since it is continuous by Lemma 2.16 and \((\mathcal{R}, \rho) \) is a compact metric space by Theorem 2.10. By Lemma 2.14 (i),
\[
\rho \left( \left( \bar{\mu}^{(N)}, \bar{m}^{(N)} \right), \left( \bar{\mu}^{(N+1)}, \bar{m}^{(N+1)} \right) \right) \underset{N \to \infty}{\to} 0.
\]
We get by the sequential characterization of the uniform continuity that
\[
\rho \left( \left( \mu^{(N+1)}, m^{(N+1)} \right), \left( \mu^{(N+2)}, m^{(N+2)} \right) \right) = \rho \left( \Theta \left( \mu^{(N)}, \bar{m}^{(N)} \right), \Theta \left( \bar{\mu}^{(N+1)}, \bar{m}^{(N+1)} \right) \right) \underset{N \to \infty}{\to} 0.
\]

\( \square \)
2.3.2. Main convergence result

In this section, we prove the convergence of the algorithm. To do so, we first introduce the following sequence of real numbers \( \varepsilon_N \), which quantifies how far \((\bar{\mu}^{(N)}, \bar{m}^{(N)})\) is from being the best response when the reward maps depend on \((\bar{m}^{(N)}, \bar{m}^{(N)})\). Therefore, \( \varepsilon_N \) quantifies the proximity of \((\bar{\mu}^{(N)}, \bar{m}^{(N)})\) from an LP MFG Nash equilibrium.

**Definition 2.18 (Exploitability).** We define the sequence of real numbers \( (\varepsilon_N)_{N \geq 1} \) by

\[
\varepsilon_N = \left\langle f\left(\bar{m}^{(N)}\right), m^{(N+1)} - \bar{m}^{(N)}\right\rangle + \left\langle g\left(\bar{\mu}^{(N)}\right), \mu^{(N+1)} - \bar{\mu}^{(N)}\right\rangle \geq 0. \tag{2.2}
\]

In particular, \((\bar{\mu}^{(N)}, \bar{m}^{(N)})\) is an \( \varepsilon_N \)-LP MFG Nash equilibrium and we will show in the next theorem that \( \varepsilon_N \to 0 \) as \( N \to \infty \).

**Proof of Theorem 2.5.** In the proof we will denote by \( C \geq 0 \) a generic constant which may change from line to line. Recall the expression of \( \varepsilon_N \) from (2.2). We can rewrite \( \varepsilon_N \) as

\[
\varepsilon_N = \Gamma\left[\bar{\mu}^{(N)}, \bar{m}^{(N)}\right] \left(\mu^{(N+1)}, m^{(N+1)}\right) - \Gamma\left[\bar{\mu}^{(N)}, \bar{m}^{(N)}\right] \left(\bar{\mu}^{(N)}, \bar{m}^{(N)}\right).
\]

Now we have

\[
\varepsilon_{N+1} - \varepsilon_N = \Gamma\left[\bar{\mu}^{(N+1)}, \bar{m}^{(N+1)}\right] \left(\mu^{(N+1)}, m^{(N+1)}\right) - \Gamma\left[\bar{\mu}^{(N+1)}, \bar{m}^{(N+1)}\right] \left(\bar{\mu}^{(N+1)}, \bar{m}^{(N+1)}\right)
- \Gamma\left[\bar{\mu}^{(N)}, \bar{m}^{(N)}\right] \left(\mu^{(N+1)}, m^{(N+1)}\right) + \Gamma\left[\bar{\mu}^{(N)}, \bar{m}^{(N)}\right] \left(\bar{\mu}^{(N)}, \bar{m}^{(N)}\right).
\]

Define

\[
\varepsilon^{(1)}_N := \Gamma\left[\bar{\mu}^{(N)}, \bar{m}^{(N)}\right] \left(\mu^{(N)}, m^{(N)}\right) - \Gamma\left[\bar{\mu}^{(N+1)}, \bar{m}^{(N+1)}\right] \left(\bar{\mu}^{(N+1)}, \bar{m}^{(N+1)}\right),
\]

\[
\varepsilon^{(2)}_N := \Gamma\left[\bar{\mu}^{(N+1)}, \bar{m}^{(N+1)}\right] \left(\mu^{(N+2)}, m^{(N+2)}\right) - \Gamma\left[\bar{\mu}^{(N)}, \bar{m}^{(N)}\right] \left(\bar{\mu}^{(N+1)}, \bar{m}^{(N+1)}\right).
\]

Then \( \varepsilon_{N+1} - \varepsilon_N = \varepsilon^{(1)}_N + \varepsilon^{(2)}_N \). Let us make some estimates of these two quantities. Using Lemma 2.14 (ii), for each \( t \in [0, T] \) and \( x \in \mathcal{O} \) we obtain

\[
\left| f\left(t, x, \bar{m}^{(N+1)}_t\right) - f\left(t, x, \bar{m}^{(N)}_t\right) \right| \leq C f(1 + |x|) \int_0^t (1 + |z|^p) \left| \bar{m}^{(N+1)}_t - \bar{m}^{(N)}_t \right| (dz) \leq \frac{C}{N} (1 + |x|),
\]

and therefore we get by Lemma 2.6 (i)

\[
- \frac{1}{N+1} \left( f\left(\bar{m}^{(N+1)}\right) - f\left(\bar{m}^{(N)}\right), m^{(N+1)} - \bar{m}^{(N)}\right) \leq \frac{1}{N+1} \left( \left| f\left(\bar{m}^{(N+1)}\right) - f\left(\bar{m}^{(N)}\right)\right|, m^{(N+1)} + \bar{m}^{(N)}\right) \leq \frac{C}{N^2}.
\]

We deduce that

\[
\left\langle f\left(\bar{m}^{(N)}\right), \bar{m}^{(N)} \right\rangle - \left\langle f\left(\bar{m}^{(N+1)}\right), \bar{m}^{(N+1)} \right\rangle = \left\langle f\left(\bar{m}^{(N)}\right), \bar{m}^{(N)} \right\rangle
- \left\langle f\left(\bar{m}^{(N+1)}\right), \bar{m}^{(N)} + \frac{1}{N+1} \left( m^{(N+1)} - \bar{m}^{(N)} \right) \right\rangle
= \left\langle f\left(\bar{m}^{(N)}\right) - f\left(\bar{m}^{(N+1)}\right), \bar{m}^{(N)} \right\rangle
- \frac{1}{N+1} \left\langle f\left(\bar{m}^{(N+1)}\right), m^{(N+1)} - \bar{m}^{(N)} \right\rangle.
\]
Now, by Lemma 2.15,
\[ \langle f(\bar{m}(N)) - f(\bar{m}(N+1)), \bar{m}(N) \rangle \]
\[ \leq \frac{1}{N+1} \langle f(\bar{m}(N)), m^{(N+1)} - \bar{m}(N) \rangle + C \frac{N}{N^2}. \]

Analogously,
\[ \langle g(\bar{\mu}(N)), \bar{\mu}(N) \rangle - \langle g(\bar{\mu}(N+1)), \bar{\mu}(N+1) \rangle \leq \langle g(\bar{\mu}(N)) - g(\bar{\mu}(N+1)), \bar{\mu}(N) \rangle \]
\[ - \frac{1}{N+1} \langle g(\bar{\mu}(N)), \mu^{(N+1)} - \bar{\mu}(N) \rangle + C \frac{N}{N^2}. \]

Therefore,
\[ \varepsilon^{(1)}_N = \langle f(\bar{m}(N)), \bar{m}(N) \rangle + \langle g(\bar{\mu}(N)), \bar{\mu}(N) \rangle - \langle f(\bar{m}(N+1)), \bar{m}(N+1) \rangle - \langle g(\bar{\mu}(N+1)), \bar{\mu}(N+1) \rangle \]
\[ \leq \langle f(\bar{m}(N)) - f(\bar{m}(N+1)), \bar{m}(N) \rangle + \langle g(\bar{\mu}(N)) - g(\bar{\mu}(N+1)), \bar{\mu}(N) \rangle - \frac{\varepsilon_N}{N+1} + C \frac{N}{N^2}. \]

On the other hand,
\[ \varepsilon^{(2)}_N = \Gamma \left[ \bar{\mu}^{(N+1)}, \bar{m}^{(N+1)} \right] \left[ \mu^{(N+2)}, m^{(N+2)} \right] - \Gamma \left[ \bar{\mu}^{(N)}, \bar{m}^{(N)} \right] \left[ \mu^{(N+1)}, m^{(N+1)} \right] \]
\[ \leq \Gamma \left[ \bar{\mu}^{(N+1)}, \bar{m}^{(N+1)} \right] \left[ \mu^{(N+2)}, m^{(N+2)} \right] - \Gamma \left[ \bar{\mu}^{(N)}, \bar{m}^{(N)} \right] \left[ \mu^{(N+2)}, m^{(N+2)} \right] \]
\[ = \langle f(\bar{m}(N+1)) - f(\bar{m}(N)), m^{(N+2)} \rangle + \langle g(\bar{\mu}(N+1)) - g(\bar{\mu}(N)), \mu^{(N+2)} \rangle \]
\[ = \langle f(\bar{m}(N+1)) - f(\bar{m}(N)), m^{(N+1)} \rangle + \langle g(\bar{\mu}(N+1)) - g(\bar{\mu}(N)), \mu^{(N+1)} \rangle \]
\[ + \langle f(\bar{m}(N+1)) - f(\bar{m}(N)), m^{(N+2)} - m^{(N+1)} \rangle + \langle g(\bar{\mu}(N+1)) - g(\bar{\mu}(N)), \mu^{(N+2)} - \mu^{(N+1)} \rangle. \]

Now, by Lemma 2.15,
\[ \langle f(\bar{m}(N+1)) - f(\bar{m}(N)), m^{(N+2)} - m^{(N+1)} \rangle \leq \frac{C_f}{N} d_M(m^{(N+1)}, m^{(N+2)}), \]
\[ \langle g(\bar{\mu}(N+1)) - g(\bar{\mu}(N)), \mu^{(N+2)} - \mu^{(N+1)} \rangle \leq \frac{C_g}{N} W_1(\mu^{(N+1)}, \mu^{(N+2)}). \]

Therefore
\[ \varepsilon^{(2)}_N \leq \langle f(\bar{m}(N+1)) - f(\bar{m}(N)), m^{(N+1)} \rangle + \langle g(\bar{\mu}(N+1)) - g(\bar{\mu}(N)), \mu^{(N+1)} \rangle \]
\[ + \frac{C}{N} \left( d_M(m^{(N+1)}, m^{(N+2)}) + W_1(\mu^{(N+1)}, \mu^{(N+2)}) \right). \]

Letting
\[ \delta_N = C \left[ d_M(m^{(N+1)}, m^{(N+2)}) + W_1(\mu^{(N+1)}, \mu^{(N+2)}) + \frac{1}{N} \right], \]
we get
\[ \varepsilon_{N+1} - \varepsilon_N = \varepsilon^{(1)}_N + \varepsilon^{(2)}_N \leq \langle f(\bar{m}(N)) - f(\bar{m}(N+1)), \bar{m}(N) \rangle + \langle g(\bar{\mu}(N)) - g(\bar{\mu}(N+1)), \bar{\mu}(N) \rangle - \frac{\varepsilon_N}{N+1} \]
\[ + \langle f(\bar{m}(N+1)) - f(\bar{m}(N)), m^{(N+1)} \rangle + \langle g(\bar{\mu}(N+1)) - g(\bar{\mu}(N)), \mu^{(N+1)} \rangle + \delta_N \]
\[ = \langle f(\bar{m}(N+1)) - f(\bar{m}(N)), m^{(N+1)} - \bar{m}(N) \rangle + \langle g(\bar{\mu}(N+1)) - g(\bar{\mu}(N)), \mu^{(N+1)} - \bar{\mu}(N) \rangle - \frac{\varepsilon_N}{N+1} + \delta_N. \]
\[= (N + 1) \left[ \langle f(\bar{m}^{N+1}) - f(m^{N}), \bar{m}^{N+1} - m^{N} \rangle + \langle g(\bar{\mu}^{N+1}) - g(\bar{\mu}^{N}), \bar{\mu}^{N+1} - \bar{\mu}^{N} \rangle \right] \]
\[= \frac{\varepsilon_N}{N + 1} + \frac{\delta_N}{N} \]
\[\leq \frac{\varepsilon_N}{N + 1} + \frac{\delta_N}{N},\]

where the last inequality comes from the Lasry–Lions monotonicity condition. Observe that \(\delta_N \to 0\) by Corollary 2.17. By Lemma 3.1 in [28], we conclude that \(\varepsilon_N \to 0\) as \(N \to \infty\). Let \(((\mu, m), (\bar{\mu}, \bar{m}))\) be a cluster point of the sequence \(((\mu^{N+1}, m^{N+1}), (\bar{\mu}^{N+1}, \bar{m}^{N+1}))_{N \geq 1}\) for the topology \(\tau_p \otimes \bar{\tau}_p\) and let us show that \((\mu, m) = (\bar{\mu}, \bar{m})\), which implies that \((\mu, m)\) is an LP MFG Nash equilibrium by continuity of the map \(\Theta\) (see Lemma 2.16). First note that since \((\mu^{N+1}, m^{N+1}) = \Theta(\bar{\mu}^{N}, \bar{m}^{N})\), and \(\Theta\) is continuous, we obtain \((\mu, m) = \Theta(\bar{\mu}, \bar{m})\). Let \((\bar{\mu}, \bar{m}) \in \mathcal{R}\). We have

\[\Gamma[\bar{\mu}(N), \bar{m}(N)](\mu^{N+1}, m^{N+1}) \geq \Gamma[\bar{\mu}(N), \bar{m}(N)](\bar{\mu}, \bar{m}) - \varepsilon_N.\]

By definition of \(\varepsilon_N\),

\[\Gamma[\bar{\mu}(N), \bar{m}(N)](\mu^{N+1}, m^{N+1}) \geq \Gamma[\bar{\mu}(N), \bar{m}(N)](\bar{\mu}, \bar{m}) - \varepsilon_N.\]

Taking the limit \(N \to \infty\), we obtain \(\Gamma[\bar{\mu}, \bar{m}](\mu, m) \geq \Gamma[\bar{\mu}, \bar{m}](\bar{\mu}, \bar{m})\). Since \((\bar{\mu}, \bar{m})\) was arbitrary in \(\mathcal{R}\), we get \((\mu, m) = \Theta(\bar{\mu}, \bar{m}) = (\mu, m)\), i.e. \((\bar{\mu}, \bar{m}) = (\mu, m)\) is the unique LP MFG Nash equilibrium. □

**Remark 2.19.** The proof follows some of the steps given in [28], but is based on some new results due to our setting of optimal stopping MFGs (in particular, the flow of measures is discontinuous). More precisely, one needs to establish specific estimates using appropriate distances.

### 3. Linear Programming Algorithm for MFGs with pure control and absorption

In this section, we illustrate the LPFP algorithm for MFGs with pure control and absorption, its convergence following by the same approach developed in the case of optimal stopping (see Theorem 2.5). In the setting of MFGs with pure control and absorption, the players control their dynamics up to the exit time from a given set \(\mathcal{O}\), when they leave the game. For the reader’s convenience, we keep the same notations as in the optimal stopping case with some adaptations of the definitions.

Let \(U\) be the set of flows of measures on \(\bar{\mathcal{O}} \times A\), \((m_t)_{t \in [0,T]}\), such that: for every \(t \in [0, T]\), \(m_t\) is a Borel finite signed measure on \(\bar{\mathcal{O}} \times A\), for every \(B \in \mathcal{B}(\bar{\mathcal{O}} \times A)\), the mapping \(t \mapsto m_t(B)\) is measurable, and \(\int_0^T |m_t|(\bar{\mathcal{O}} \times A)dt < \infty\), where \(|m_t|\) is the total variation measure of \(m_t\). The definitions of \(\bar{U}, \bar{U}_p, V\), and \(V_p\) from the previous section are adapted in a similar way. The topology \(\tau_p\) denotes, as in the previous section, the weak topology with respect to continuous functions with \(p\)-growth. The topology \(\bar{\tau}_p\) stands for the stable topology in \(V_p\) where test functions of \((t, x, a)\) are allowed to be only measurable with respect to \(t\) and have \(p\)-growth.

By the disintegration theorem, for each \((m_t)_{t \in [0,T]} \in V\), there exists a mapping \(\nu_{t,x} : [0, T] \times \bar{\mathcal{O}} \to \mathcal{P}(A)\) such that for each \(B \in \mathcal{B}(A)\), the function \((t, x) \mapsto \nu_{t,x}(B)\) is \(\mathcal{B}([0,T] \times \bar{\mathcal{O}})\)-measurable, and

\[m_t(dx, da)dt = \nu_{t,x}(da)m_t^x(dx)dt,
\]

where \(m_t^x(dx) := \int_A m_t(dx, da)\). Here \(\nu_{t,x}\) is interpreted as a Markovian relaxed control and in the case when \(\nu_{t,x}\) is a Dirac measure, it is called Markovian strict control (see [24] for more details).

We define the parabolic boundary as the set \(\Sigma = ([0, T] \times \partial \mathcal{O}) \cup \{(T) \times \bar{\mathcal{O}}\}\). We are given constants \(q > p \geq 1\forall r\), where \(r \in [0, 2]\) and \(q \geq 2\), and the following functions:

\[(b, \sigma) : [0, T] \times \mathbb{R} \times A \to \mathbb{R}, \quad f : [0, T] \times \bar{\mathcal{O}} \times \mathcal{P}_p^{\text{sub}}(\mathcal{O}) \times A \to \mathbb{R}, \quad g : \Sigma \times \mathcal{P}_p(\Sigma) \to \mathbb{R}.
\]

Consider the following assumptions, under which existence of LP MFG Nash equilibria can be shown.
Assumption 3.

(1) $m^* \in \mathcal{P}_p(\mathcal{O})$.

(2) $\mathcal{O}$ is a bounded open interval, $\sigma$ does not depend on the control $a$ and for all $(t, x) \in [0, T] \times \mathbb{R}$, $\sigma^2(t, x) \geq c_\sigma$ for some $c_\sigma > 0$.

(3) The functions $(t, x, a) \mapsto b(t, x, a)$ and $(t, x) \mapsto \sigma(t, x)$ are jointly measurable and continuous in $(x, a)$ and $x$ respectively, for each $t$. Moreover, there exists a constant $c_1 > 0$ such that for all $(t, x, y, a) \in [0, T] \times \mathbb{R} \times \mathbb{R} \times A$,

$$|b(t, x, a) - b(t, y, a)| + |\sigma(t, x) - \sigma(t, y)| \leq c_1|x - y|,$$

$$|b(t, x, a)| \leq c_1[1 + |x|^2].$$

(4) The function $(t, x, \eta, a) \mapsto f(t, x, \eta, a)$ is jointly measurable and continuous in $(x, \eta, a)$ for each $t$. The function $g$ is continuous. Moreover, there exists a constant $c_2 > 0$ such that for all $(t, x, \eta, a, (\bar{t}, \bar{x}), \mu) \in [0, T] \times \mathcal{O} \times \mathcal{P}_{p}^{\text{sub}}(\mathcal{O}) \times A \times \Sigma \times \mathcal{P}_p(\Sigma)$,

$$|f(t, x, \eta, a)| \leq c_2\left[1 + |x|^p + \int_{\mathcal{O}} |z|^p q(dz)\right], \quad |g(\bar{t}, \bar{x}, \mu)| \leq c_2\left[1 + |\bar{x}|^p + \int_{\Sigma} |z|^p \mu(ds, dz)\right].$$

We give below the linear programming formulation of the MFG problem with pure control and absorption, which has been introduced in [24].

Definition 3.1. Let $\mathcal{R}$ be the set of pairs $(\mu, m) \in \mathcal{P}_p(\Sigma) \times V_p$, such that for all $u \in C^{1,2}_b([0, T] \times \mathcal{O})$,

$$\int_{\Sigma} u(t, x) \mu(dt, dx) = \int_{\mathcal{O}} u(0, x)m_0(dx) + \int_0^T \int_{\mathcal{O} \times A} (\partial_t u + \mathcal{L}u)(t, x, a)m_t(dx, da)dt,$$

where

$$\mathcal{L}u(t, x, a) := b(t, x, a) \partial_x u(t, x) + \frac{\sigma^2}{2}(t, x) \partial_{xx} u(t, x).$$

Definition 3.2 (LP formulation of the MFG problem). For $(\bar{\mu}, \bar{m}) \in \mathcal{P}_p(\Sigma) \times V_p$, let $\Gamma[\bar{\mu}, \bar{m}] : \mathcal{P}_p(\Sigma) \times V_p \to \mathbb{R}$ be defined by

$$\Gamma[\bar{\mu}, \bar{m}](\mu, m) = \int_0^T \int_{\mathcal{O} \times A} f(t, x, \bar{m}^*_t, \mu)m_t(dx, da)dt + \int_{\Sigma} g(t, x, \bar{\mu})\mu(dt, dx).$$

We say that $(\mu^*, m^*) \in \mathcal{P}_p(\Sigma) \times V_p$ is an LP MFG Nash equilibrium if $(\mu^*, m^*) \in \mathcal{R}$ and for all $(\mu, m) \in \mathcal{R}$,

$$\Gamma[\mu^*, m^*](\mu, m) \leq \Gamma[\mu^*, m^*](\mu^*, m^*).$$

Observe that, for a given $(\bar{\mu}, \bar{m}) \in \mathcal{P}_p(\Sigma) \times V_p$, the instantaneous reward function $f$ only depends on the marginal in $x$ of $\bar{m}$, i.e. $\bar{m}^*$. Henceforth, $f$ does not depend on the distribution of the controls. Note that in this setting, due to the absorption feature of the game, the flow of measures $(m_t)$ is not necessarily continuous. Under Assumption 3, one can show existence of an LP MFG Nash equilibrium by using the tools developed in the section on optimal stopping, which allow to prove existence in a much more general framework than in [24] (in particular, $f$, $g$, $b$ and $\sigma$ might have polynomial growth with respect to $(x, m, \mu)$ and the reward maps $f$ and $g$ are allowed to have a general dependence on the measures $m$, resp. $\mu$).

Assumption 4. We assume the following:

(1) There exist functions $f_1 : [0, T] \times \mathcal{O} \times \mathcal{P}_{p}^{\text{sub}}(\mathcal{O}) \to \mathbb{R}$ and $f_2 : [0, T] \times \mathcal{O} \times A \to \mathbb{R}$ satisfying the same conditions as $f$ and such that $f = f_1 + f_2$.

(2) For each $(\bar{\mu}, \bar{m}) \in \mathcal{R}$, there exists a unique maximizer of $\Gamma[\bar{\mu}, \bar{m}]$ on $\mathcal{R}$.
(3) The Lasry–Lions monotonicity condition holds: for all \((\mu, m)\) and \((\bar{\mu}, \bar{m})\) in \(\mathcal{P}_p(\Sigma) \times V_p\),
\[
\langle f_1(m^x) - f_1(\bar{m}^x), m^x - \bar{m}^x \rangle + \langle g(\mu) - g(\bar{\mu}), \mu - \bar{\mu} \rangle \leq 0.
\]
(4) There exist constants \(c_f \geq 0\) and \(c_g \geq 0\) such that for all \(t \in [0, T]\), \(x, x' \in \bar{\Omega}\), \(\eta, \eta' \in \mathcal{P}_p^{\text{sub}}(\bar{\Omega})\), \((\bar{t}, \bar{x})\), \((\bar{t}', \bar{x}')\) \in \(\Sigma, \mu, \mu' \in \mathcal{P}_p(\Sigma)\),
\[
|f_1(t, x, \eta) - f_1(t, x, \eta')| \leq c_f(1 + |x|) \int_{\bar{\Omega}} (1 + |\eta|) \eta - \eta' |(dz),
\]
\[
|f_1(t, x, \eta) - f_1(t, x, \eta') - f_1(t, x', \eta) + f_1(t, x', \eta')| \leq c_f|x - x'| \int_{\bar{\Omega}} (1 + |\eta|) \eta - \eta' |(dz),
\]
\[
|g(\bar{t}, \bar{x}, \mu) - g(\bar{t}, \bar{x}, \mu')| \leq c_g(1 + |\bar{x}|) \int_{\Sigma} (1 + |\mu|) \mu - \mu' |(ds, dz),
\]
\[
|g(\bar{t}, \bar{x}, \mu) - g(\bar{t}, \bar{x}, \mu') - g(\bar{t}', \bar{x}', \mu) + g(\bar{t}', \bar{x}', \mu')| \leq c_g(|\bar{t} - \bar{t}'| + |\bar{x} - \bar{x}'|) \int_{\Sigma} (1 + |\mu|) \mu - \mu' |(ds, dz).
\]

For sufficient conditions on the coefficients under which the above assumptions hold, the reader is referred to Appendix E. Using the same arguments as in Proposition 2.4, one can show that there exists at most one LP MFG Nash equilibrium.

We propose the following algorithm for computing the LP MFG Nash equilibrium.

**Algorithm 2: LPFP algorithm (MFGs with pure control and absorption)**

**Data:** A number of steps \(N\) for the equilibrium approximation; a pair \((\bar{\mu}^{(0)}, \bar{m}^{(0)})\) \(\in \mathcal{R}\);
**Result:** Approximate LP MFG Nash equilibrium

1. for \(\ell = 0, 1, \ldots, N - 1\) do
2. Compute a linear programming best response \((\mu^{(\ell+1)}, m^{(\ell+1)})\) to \((\bar{\mu}^{(\ell)}, \bar{m}^{(\ell)})\) by solving the linear programming problem
\[
\arg \max_{(\mu, m) \in \mathcal{R}} \Gamma[\bar{\mu}^{(\ell)}, \bar{m}^{(\ell)}](\mu, m).
\]
3. Set \((\bar{\mu}^{(\ell+1)}, \bar{m}^{(\ell+1)}) := \frac{\ell}{\ell + 1} (\bar{\mu}^{(\ell)}, \bar{m}^{(\ell)}) + \frac{1}{\ell + 1} (\mu^{(\ell+1)}, m^{(\ell+1)}) = \frac{1}{\ell + 1} \sum_{\nu=1}^{\ell+1} (\mu^{(\nu)}, m^{(\nu)})
4. end

Using the topology of the convergence in measure (which is denoted by \(\bar{\tau}_p\)) for the marginals \(m^x\) given by \(m^x_t(dx) = \int_A m_t(dx, da)\) and appropriate estimates (given in terms of well chosen metrics), the convergence of the algorithm follows by similar arguments as in Theorem 2.5.

**Theorem 3.3 (Convergence of the algorithm).** Let Assumptions 3 and 4 hold true and consider the sequences \((\bar{\mu}^{(N)}, \bar{m}^{(N)})_{N \geq 1}\) and \((\mu^{(N)}, m^{(N)})_{N \geq 1}\) generated by the Algorithm 2. Then both sequences converge in the product topology \(\tau_p \otimes \bar{\tau}_p\) to the unique LP MFG Nash equilibrium \((\mu^*, m^*)\). Furthermore, the sequences \((\bar{\mu}^{(N)}, \bar{m}^{x,(N)})_{N \geq 1}\) and \((\mu^{(N)}, m^{x,(N)})_{N \geq 1}\) converge in the product topology \(\tau_p \otimes \bar{\tau}_p\) to \((\mu^*, m^{x,*})\).

**Numerical example.** We now illustrate the LPFP algorithm for MFGs with pure control and absorption through a numerical example. In this example, let \(T = 1\) and assume that the state of the representative player belongs to the domain \(\bar{\Omega}\) with \(\bar{\Omega} = [-2, 2]\), and is given by
\[
X^\alpha_t = X^\alpha_0 + \int_0^t \alpha_s ds + W_t,
\]
i.e. \(b(t, x, a) = a\) and \(\sigma(t, x, a) = 1\). The control \(\alpha\) is assumed to take values in \(A = [-1, 1]\). The initial states of the players are distributed according to the law \(\mathcal{N}(0, 0.1)\) truncated to \(\bar{\Omega}\).
Before exiting the game at time $\tau_{\Gamma} X^\alpha \wedge T$, the representative player receives an instantaneous reward

$$-10 \int_{[-2,2]} e^{-|X_t^\alpha - y|} q(dy) - 2||X_t^\alpha| - 1| - a_t^2,$$

and the terminal reward at exit time is given by $-\left|X_{\tau_{\Gamma} X^\alpha \wedge T}\right|$, that is:

$$f(t, x, \eta, a) = -10 \int_{[-2,2]} e^{-|x-y|} q(dy) - 2||x| - 1| - a^2, \quad g(t, x, \mu) = -|x|.$$

During the game, players have an incentive to be near the points $-1$ or $1$, and converge to the point $0$ at the final time, but at the same time the mean-field dependence creates an incentive to be far from other players.

We discretize the linear program in a similar way to the optimal stopping case. More precisely, we consider a time grid $t_i = i\Delta$ with $\Delta = \frac{T}{n_t}$, for $i \in \{0, 1, \ldots n_t\}$, a state grid $x_{j+1} = x_j + \delta$, for $j \in \{0, 1, \ldots n_s - 1\}$ with $x_0 \in \mathbb{R}$ and $\delta > 0$ and an action grid $a_0 < \cdots < a_{n_a}$. We define

$$Lu(t, x, a) = \frac{\partial u}{\partial t}(t, x) + b(t, x, a) \frac{\partial u}{\partial x}(t, x) + \frac{\sigma^2}{2} \frac{\partial^2 u}{\partial x^2}(t, x), \quad \forall u \in \mathcal{D}(L) := C^{1,2}_b([0, T] \times \mathcal{O}).$$

We set $\mathcal{D}(\hat{L})$ as the functions in $\mathcal{D}(L) = C^{1,2}_b([0, T] \times \mathcal{O})$ restricted to the time-state discretization grid. For $u \in \mathcal{D}(\hat{L})$, we discretize the derivatives as follows

$$\hat{L}_t u(t_i, x_j) = \frac{1}{\Delta} [u(t_{i+1}, x_j) - u(t_i, x_j)],$$

$$\hat{L}_x u(t_i, x_j, a_k) = \frac{1}{\delta} \max(b(t_i, x_j, a_k), 0)[u(t_{i+1}, x_{j+1}) - u(t_{i+1}, x_j)],$$

$$\hat{L}^d_x u(t_i, x_j, a_k) = \frac{1}{\delta} \min(b(t_i, x_j, a_k), 0)[u(t_{i+1}, x_j) - u(t_{i+1}, x_{j-1})],$$

$$\hat{L}_{xx} u(t_i, x_j) = \frac{1}{\delta^2} \frac{\sigma^2}{2} (t_i, x_j)[u(t_{i+1}, x_{j+1}) + u(t_{i+1}, x_{j-1}) - 2u(t_{i+1}, x_j)].$$

The discretized generator has the form:

$$\hat{L} u(t_i, x_j, a_k) = \hat{L}_t u(t_i, x_j) + \hat{L}_x^u u(t_i, x_j, a_k) + \hat{L}^d_x u(t_i, x_j, a_k) + \hat{L}_{xx} u(t_i, x_j).$$

The constraint reads as

$$\sum_{i=0}^{n_t-1} \sum_{j \in \{0, n_s\}} u(t_i, x_j) \mu(t_i, x_j) + \sum_{i=0}^{n_s} u(t_n_s, x_j) \mu(t_n_s, x_j)$$

$$- \Delta \sum_{i=0}^{n_t-1} \sum_{j=1}^{n_s} \sum_{k=0}^{n_s} \hat{L} u(t_i, x_j, a_k) m(t_i, x_j, a_k) = \sum_{j=1}^{n_s} u(t_0, x_j) m_0^\ast(x_j),$$

for $u \in \mathcal{D}(\hat{L})$. As in the optimal stopping case, it suffices to evaluate the constraint on the set of indicator functions. The discretized reward associated to a discrete mean-field term ($\hat{\mu}, \hat{m}$) is given by

$$\sum_{i=0}^{n_t-1} \sum_{j \in \{0, n_s\}} g(t_i, x_j, \hat{\mu}(t_i, x_j)) \mu(t_i, x_j) + \sum_{i=0}^{n_s} g(t_{n_s}, x_j, \hat{\mu}) \mu(t_{n_s}, x_j) + \Delta$$

$$\times \sum_{i=0}^{n_t-1} \sum_{j=1}^{n_s} \sum_{k=0}^{n_s} f(t_i, x_j, \hat{m}^\ast(t_i, \cdot), a_k) m(t_i, x_j, a_k).$$
Figure 3. Equilibrium distributions at the final iteration. Top: $\bar{\mu}(N) (\cdot \times \{2\})$. Middle left: $\bar{m}(N)$, distribution of the players still in the game over time. Middle right: $\bar{\mu}(N) (\{T\} \times \cdot)$. Bottom: $\bar{\mu}(N) (\cdot \times \{-2\})$.

The generator obtained using these approximations is associated to the following controlled Markov chain (see p. 328 in [37]):

$$P(Y_{t+1} = x_j | Y_t = x_j, \alpha_t = a_k) = 1 - \sigma^2(t_i, x_j) \frac{\Delta}{\delta^2} - |b(t_i, x_j, a_k)| \frac{\Delta}{\delta},$$

$$P(Y_{t+1} = x_{j+1} | Y_t = x_j, \alpha_t = a_k) = \frac{\sigma^2}{2} (t_i, x_j) \frac{\Delta}{\delta^2} + b^+(t_i, x_j, a_k) \frac{\Delta}{\delta},$$

$$P(Y_{t+1} = x_{j-1} | Y_t = x_j, \alpha_t = a_k) = \frac{\sigma^2}{2} (t_i, x_j) \frac{\Delta}{\delta^2} + b^-(t_i, x_j, a_k) \frac{\Delta}{\delta}.$$  

For this to be well defined, we should have for all $i$, $j$ and $k$

$$\Delta \leq \frac{\delta^2}{\sigma^2(t_i, x_j) + \delta |b(t_i, x_j, a_k)|}.$$
The discretized constraint coincides with the constraint associated to the controlled Markov chain $Y$ (with absorption on $\{x_0, x_{n_s}\}$).

At each iteration the exploitability writes:

\[
\varepsilon_N = \Delta \sum_{i=0}^{n_t-1} \sum_{j=1}^{n_s-1} \sum_{k=0}^{n_a} f(t_i, x_j, \tilde{m}^{x_i(N-1)}(t_i, \cdot), a_k) \left( m^{(N)}(t_i, x_j, a_k) - \tilde{m}^{(N-1)}(t_i, x_j, a_k) \right) \\
+ \sum_{i=0}^{n_t} \sum_{j \in \{0, n_s\}} g(t_i, x_j, \tilde{\mu}^{(N-1)}(t_i, x_j)) \left( \mu^{(N)}(t_i, x_j) - \tilde{\mu}^{(N-1)}(t_i, x_j) \right) \\
+ \sum_{j=0}^{n_s} g(t_{n_t}, x_j, \tilde{\mu}^{(N-1)}(t_{n_t}, x_j)) \left( \mu^{(N)}(t_{n_t}, x_j) - \tilde{\mu}^{(N-1)}(t_{n_t}, x_j) \right).
\]

In Figure 3, we observe the distribution of the players still in the game over time together with the exit distributions at the boundary and the distribution of the players at the terminal time. Figure 4 shows the Markovian control given by $\tilde{\alpha}_N(t,x) = \int_A \tilde{a}_i^{(N)}(da)$ (which is the optimal control since $A$ is convex, $b$ is affine in $a$ and $f$ is strictly concave in $a$, see the proof of Theorem E.2 for more details). We see that players starting in a positive state use a positive control at the beginning to be near the point 1 and switch to a negative control.
towards the end of the game to be close to 0. On the other hand, the players starting in a negative state use
the opposite strategy. Finally, Figure 5 illustrates the convergence of the algorithm through the measurement
of the exploitability.

**Appendix A. Polynomial growth topologies for measures**

Let \((E, d)\) be a complete and separable metric space. We endow \(\mathcal{M}^*(E)\) with the topology of weak convergence \(\tau_0 \coloneqq \sigma(\mathcal{M}^*(E), C_b(E))\). The relative topology in \(\mathcal{M}(E)\) is completely metrizable through the bounded Lipschitz distance (see \([11]\), volume II, p. 192 and Theorem 8.3.2 p. 193)

\[
d_{BL}(\mu^1, \mu^2) \coloneqq \sup \left\{ \int_E \varphi(x)(\mu^1 - \mu^2)(dx) : \varphi \in BL(E), \|\varphi\|_{BL} \leq 1 \right\}, \quad \mu^1, \mu^2 \in \mathcal{M}(E),
\]

where \(BL(E)\) is the space of all bounded Lipschitzian functions on \(E\) with the norm

\[
\|\varphi\|_{BL} \coloneqq \|\varphi\|_{\infty} + \sup_{x \neq y} \frac{|\varphi(x) - \varphi(y)|}{|x - y|}.
\]

Let \(p \geq 1\) and \(x_0\) be an arbitrary point in \(E\) and define the function \(\psi : E \to \mathbb{R}\) by \(\psi(x) = 1 + d(x, x_0)^p\). Consider the class of functions

\[
C_p(E) = \left\{ \phi \in C(E) : \sup_{x \in E} \frac{\left|\phi(x)\right|}{\psi(x)} < \infty \right\}
\]

and define the topology \(\tau_p \coloneqq \sigma(\mathcal{M}_p^*(E), C_p(E))\) on \(\mathcal{M}_p^*(E)\).

We give below some technical results, for which we do not provide the proofs since they use standard arguments
(see e.g. Appendix A in \([38]\) and Theorem 1 in \([10]\)).

**Lemma A.1.** The function \(F : (\mathcal{M}_p^*(E), \tau_p) \to (\mathcal{M}^*(E), \tau_0)\) given by \(F(\mu) = \psi(x)\mu(dx)\) is an homeomorphism. The same function is an homeomorphism between the subspaces \((\mathcal{M}_p(E), \tau_p)\) and \((\mathcal{M}(E), \tau_0)\).

**Remark A.2.** Since \((\mathcal{M}(E), \tau_0)\) is completely metrizable through the bounded Lipschitz distance, we get that \((\mathcal{M}_p(E), \tau_p)\) is also completely metrizable by the metric

\[
d_{BL,p}(\mu^1, \mu^2) \coloneqq \sup \left\{ \int_E \varphi(x)\psi(x)(\mu^1 - \mu^2)(dx) : \varphi \in BL(E), \|\varphi\|_{BL} \leq 1 \right\}, \quad \mu^1, \mu^2 \in \mathcal{M}_p(E).
\]

In particular, for all \(\mu \in \mathcal{M}_p(E)\), \(d_{BL,p}(\mu, 0) = \int_E \psi(x)\mu(dx)\).

The following proposition characterizes the convergence in \(\tau_p\) for nonnegative measures. The proof is analogous
to the one from Theorem 7.12 in \([50]\).

**Proposition A.3.** A sequence \((\mu_n)_{n \geq 1} \subset \mathcal{M}_p(E)\) converges to \(\mu \in \mathcal{M}_p(E)\) in \(\tau_p\) if and only if \((\mu_n)_{n \geq 1}\) converges to \(\mu\) weakly and

\[
\lim_{r \to \infty} \limsup_{n \to \infty} \int_{\{x \in E : d(x, x_0)^p \geq r\}} d(x, x_0)^p \mu_n(dx) = 0. \tag{A.1}
\]

**Corollary A.4.** Assume that \(E\) is a closed subset of an Euclidean space with norm \(|\cdot|\). A set \(K \subset \mathcal{M}_p(E)\) is relatively compact in \(\tau_p\) if there exists \(q > p\) such that

\[
\sup_{\mu \in K} \int_E (1 + |x|^q)\mu(dx) < \infty.
\]
Proof. The condition
\[ \sup_{\mu \in \mathcal{K}} \int_E (1 + |x|^q) \mu(dx) < \infty, \]
implies that \( \mathcal{K} \) is tight (since the map \( x \mapsto 1 + |x|^q \) has compact level sets) and uniformly bounded in total variation norm. By Prokhorov’s Theorem (Theorem 8.6.2 in [11] Volume II), the set \( \mathcal{K} \) is relatively compact in \( \tau_0 \). Henceforth, by Proposition A.3, it suffices to show the uniform integrability condition (A.1) for a given sequence \( (\mu_n)_{n \geq 1} \subseteq \mathcal{K} \). By Hölder’s inequality, for all \( r \geq 0 \)
\[ \int_{\{x \in E : |x|^p \geq r\}} |x|^p \mu_n(dx) \leq \left[ \int_E |x|^q \mu_n(dx) \right]^{p/q} \mu_n(\{x \in E : |x|^p \geq r\})^{(q-p)/q} \]
\[ \leq C \mu_n(\{x \in E : |x|^p \geq r\})^{(q-p)/q}. \]
By Markov’s inequality,
\[ \mu_n(\{x \in E : |x|^p \geq r\}) \leq \frac{1}{r} \int_E |x|^p \mu_n(dx) \leq \frac{C}{r}. \]
This suffices to conclude. \( \square \)

Now we are interested in an analogue version of the stable convergence topology for positive measures where the test functions are allowed to have polynomial growth. Consider two complete separable metric spaces \( (E, d_E) \) and \( (F, d_F) \). The distance on the product space is given by
\[ d((x, y), (x', y')) = (d_E(x, x')^p + d_F(y, y')^p)^{1/p}, \quad (x, y) \in E \times F. \]
Let \( (x_0, y_0) \in E \times F \) and define the function
\[ \tilde{\psi} : E \times F \ni (x, y) \mapsto 1 + d((x, y), (x_0, y_0))^p \in \mathbb{R}. \]
Consider the following sets of functions, which are measurable in the first component and continuous in the second one:
\[ M_{mc}(E \times F) = \{ \phi \in M_b(E \times F) : \forall x \in E, \phi(x, \cdot) \in C(F) \}, \]
\[ M_{mc,p}(E \times F) = \left\{ \phi \in M(E \times F) : \forall x \in E, \phi(x, \cdot) \in C(F), \sup_{(x, y) \in E \times F} \frac{|\phi(x, y)|}{\tilde{\psi}(x, y)} < \infty \right\}. \]
The topology \( \tilde{\tau} := \sigma(M(E \times F), M_{mc}(E \times F)) \) is known as the topology of stable convergence (see [32]). We are interested in studying the space \( M_p(E \times F) \) endowed with the topology \( \tilde{\tau}_p := \sigma(M_p(E \times F), M_{mc,p}(E \times F)) \).

Lemma A.5. The function \( F : (M_p(E \times F), \tilde{\tau}_p) \to (M(E \times F), \tilde{\tau}) \) given by \( \tilde{F}(\mu) = \tilde{\psi}(x, y)\mu(dx, dy) \) is an homeomorphism.

Remark A.6. By Proposition 2.10 in [32], the space \( (M(E \times F), \tilde{\tau}) \) is metrizable, henceforth, \( (M_p(E \times F), \tilde{\tau}_p) \) is also metrizable.

Proposition A.7. Consider a sequence \( (\mu_n) \subseteq M_p(E \times F) \) converging to \( \mu \in M_p(E \times F) \) in \( \tau_p \). If the set of measures
\[ \left\{ \int_F \tilde{\psi}(x, y)\mu_n(dx, dy) \in \mathcal{M}(E) : n \geq 1 \right\}, \]
is relatively compact in \( (\mathcal{M}(E), \sigma(\mathcal{M}(E), M_b(E))) \), then \( (\mu_n) \) converges to \( \mu \) in \( \tilde{\tau}_p \).
APPENDIX B. CONVERGENCE IN MEASURE TOPOLOGY

Let \((E, d)\) be a complete and separable metric space endowed with the Borel \(\sigma\)-algebra and let \(M([0, T]; E)\) be the space of Borel measurable functions \(\phi : [0, T] \rightarrow E\) identified a.e. on \([0, T]\). The topology of convergence in measure in \(M([0, T]; E)\) is defined as the topology induced by the metric (see e.g. [49])

\[
d_M(\phi, \psi) = \int_0^T 1 \wedge d(\phi(t), \psi(t))dt.
\]

A sequence \((\phi_n)_{n \geq 1}\) converges to \(\phi\) in \(M([0, T]; E)\) if and only if for all \(\varepsilon > 0\)

\[
\lim_{n \to \infty} \lambda(\{t \in [0, T] : d(\phi_n(t), \phi(t)) \geq \varepsilon\}) = 0.
\]

We recall that convergence in \(M([0, T]; E)\) implies convergence of a subsequence in \(E\) t.a.e. on \([0, T]\). The topology of convergence in measure remains invariant with respect to any metric inducing the same topology as \(d\) on \(E\).

Lemma B.1. Let \(M_0 \subset M([0, T]; E)\) and assume that there exists a constant \(C \geq 0\) such that for all \(\phi, \psi \in M_0\) we have \(d(\phi(t), \psi(t)) \leq C\), t.a.e. on \([0, T]\). Then

\[
d_{M_0}(\phi, \psi) = \int_0^T d(\phi(t), \psi(t))dt, \quad \phi, \psi \in M_0
\]

metrizes the topology of convergence in measure in \(M_0\).

Proof. First note that for \((\phi_n)_{n \geq 1} \subset M_0\) and \(\phi \in M_0\),

\[
\lim_{n \to \infty} d_{M_0}(\phi_n, \phi) = 0 \Rightarrow \lim_{n \to \infty} d_M(\phi_n, \phi) = 0.
\]

The converse implication follows since the sequence \((d(\phi_n(\cdot), \phi(\cdot)))_{n \geq 1}\) converges in measure to 0 and is bounded a.e. by \(C\), which implies the convergence in \(L^1([0, T])\) to 0. \(\square\)

APPENDIX C. PROBABILISTIC REPRESENTATION

In the case when admissible measures \(m_\mu(dx)dt\) (resp. \(\mu\)) have the support included in some time-dependent domain \(O\) (resp. its complement \(O^c\)), we obtain the following probabilistic representation.

Theorem C.1. Suppose that Assumption 1 holds. Let \((\mu, m) \in \mathcal{R} \text{ and } O\) be an open subset of \([0, T] \times \bar{O}\). Assume that \(\mu(O) = 0\) and \(\int_O m_\mu(dx)dt = 0\). By Theorem C.6 in [24], there exists \((\Omega, \mathcal{F}, \mathbb{F}, W, \tau, X)\), such that \((\Omega, \mathcal{F}, \mathbb{F}, \mathbb{P})\) is a filtered probability space, \(W\) is an \(\mathbb{F}\)-Brownian motion, \(\tau\) is an \(\mathbb{F}\)-stopping time such that \(\tau \leq T \wedge \tau_X^0\) \(\mathbb{P}\)-a.s. and \(X\) is an \(\mathbb{F}\)-adapted process verifying

\[
X_t = X_0 + \int_0^t b(s, X_s)ds + \int_0^t \sigma(s, X_s)dW_s, \quad t \in [0, T], \quad \mathbb{P} \circ X_0^{-1} = m_\mu^*,
\]

such that we have the following probabilistic representation of \((\mu, m)\):

\[
\mu = \mathbb{P} \circ (\tau, X_\tau)^{-1}, \quad \text{and} \quad m_\mu(B) = \mathbb{E}^\mathbb{P}[1_B(X_t)1_{t < \tau}], \quad B \in \mathcal{B}(\bar{O}), \quad t - \text{a.e.}
\]

Assume that \(\tau_O = \tau_O \mathbb{P}\text{-a.s.},\) where

\[
\tau_O = \inf\{t \geq 0 : (t, X_t) \notin O\}, \quad \tau_\bar{O} = \inf\{t \geq 0 : (t, X_t) \notin \bar{O}\}.
\]

Then \(\tau = \tau_O \mathbb{P}\text{-a.s.}\)
Proof. Let us show that \( \tau = \tau_0 \) \( \mathbb{P} \)-a.s. Using that \( \mu \) is supported in \( O^c \) we get
\[
1 = \mu(O^c) = \mathbb{P}(\tau, X_\tau) \in O^c).
\]
Now, since \( m_t(dx)dt \) is supported in \( O \),
\[
0 = \int_{O^c} m_t(dx)dt = \mathbb{E}^p \left[ \int_0^{\tau} 1_{O^c}(t, X_t)dt \right],
\]
which means that
\[
(\mathbb{P} \otimes \lambda)(\{(\omega, t) \in \Omega \times [0, T] : (t, X_t(\omega)) \in O^c, t < \tau(\omega)\}) = 0.
\] (C.1)
By equality (C.1), we have that \( \tau_0 \leq \tau \) \( \mathbb{P} \)-a.s. Let us show now that with probability 1 we have \( \tau \leq \tau_0 \), where \( \tau_0 = \inf\{t \geq 0 : (t, X_t) \notin \bar{O}\} \). Assume that \( \mathbb{P}(\tau > \tau_0) > 0 \). Using the equality (C.2),
\[
\mathbb{P}(\lambda(\{t \in [0, T] : (t, X_t) \notin O, t < \tau\}) = 0) = 1.
\]
Define the set
\[
B = \{\tau > \tau_0\} \cap \{\lambda(\{t \in [0, T] : (t, X_t) \notin O, t < \tau\}) = 0\} \in \mathcal{F}.
\]
Let us show that \( B = \emptyset \), which will contradict the fact that \( \mathbb{P}(B) > 0 \). It is sufficient to prove that for \( \omega \in \{\tau > \tau_0\} \), we have \( \omega \notin \lambda(\{t \in [0, T] : (t, X_t(\omega)) \notin O, t < \tau\}) = 0 \}. Let \( \omega \in \{\tau > \tau_0\} \) be fixed. Since \( t \mapsto (t, X_t(\omega)) \) is continuous, we have \( (\tau_0(\omega), X_{\tau_0(\omega)}(\omega)) \in \bar{O} \). Moreover, by the definition of the infimum there exists \( \tau_1(\omega) \in [\tau_0(\omega), \tau(\omega)] \) such that \( (\tau_1(\omega), X_{\tau_1(\omega)}(\omega)) \notin \bar{O} \). Using again the continuity of \( t \mapsto (t, X_t(\omega)) \) and the fact that \( (\bar{O})^c \) is open, we can find \( \tau_1^r(\omega) \) and \( \tau_1^l(\omega) \) such that
\[
\tau_0(\omega) < \tau_1^r(\omega) < \tau_1(\omega) < \tau_1^l(\omega) < \tau(\omega) \quad \text{and} \quad \forall \, t \in [\tau_1^l(\omega), \tau_1^r(\omega)], \quad (t, X_t(\omega)) \notin \bar{O}.
\]
In particular,
\[
\lambda(\{t \in [0, T] : (t, X_t(\omega)) \notin O, t < \tau(\omega)\}) \geq \lambda([\tau_1^l(\omega), \tau_1^r(\omega)]) > 0.
\]
This shows that \( B \) is empty and contradicts the fact that it has a positive probability. We conclude that \( \mathbb{P} \)-a.s. \( \tau_0 \leq \tau \leq \tau_0 \). Since by assumption we have \( \tau_0 = \tau_0 \) \( \mathbb{P} \)-a.s., we get \( \tau = \tau_0 \) \( \mathbb{P} \)-a.s. \( \square \)

APPENDIX D. SUFFICIENT CONDITIONS FOR ASSUMPTION 2

In this section, we provide sufficient conditions on \( b, \sigma, f, g, m_0^* \) and \( O \) such that Assumption 2 is verified.

Assumption 5. We assume the following:

(1) \( O = \mathbb{R} \).
(2) \( m_0^* \) has a continuous and positive density on \( L^2(\mathbb{R}) \).
(3) \( \sigma \) is positive, does not depend on time and satisfies the uniform ellipticity condition. Moreover \( \sigma \in C^1(\mathbb{R}) \),
\[
\sup_{(t,x) \in [0,T] \times \mathbb{R}} \left[ \frac{|b(t,x)|}{\sigma(x)} + |\partial_x \sigma(x)| \right] < \infty.
\]
(4) \( f \) is of the form \( f(t,x,m) := \tilde{f}(t,x) \) and there exists \( \tilde{c}_f \geq 0 \) such that for all \( t \in [0,T], \, x, x' \in \mathbb{R}, \)
\[
|\tilde{f}(t,x) - \tilde{f}(t,x')| \leq \tilde{c}_f|x - x'|, \quad |\tilde{f}(t,x)| \leq \tilde{c}_f(1 + |x|).
\]

To be consistent with the notations used in Section 2, we will keep the notation \( f \) instead of \( \tilde{f} \).
Under the Assumptions 1 and 5, for each Theorem D.1.

Proof. Fix \((\bar{\mu}, \bar{m})\) this map writes \(\Gamma[\bar{\mu}, \bar{m}]\). Consider a complete probability space \((\Omega, \mathcal{F}, \mathbb{P})\) and \(\mathbb{P}\)-almost surely, \(\mathcal{F} = \sigma(W_t, t \leq s)\) for \(s \geq t\). Here \(\mathcal{N}\) is the set of \(\mathbb{P}\)-null sets and \(W_s = W_t + \mathcal{N}, s \geq t\), is the translated Brownian motion. Denote by \(T\) the set of stopping times with respect to this filtration with values in \([t, T]\). Consider the value function (to simplify the notation, we omit the dependence on \(\bar{\mu}\))

\[
v(t, x) = \sup_{\tau \in T(t)} \mathbb{E} \left[ \int_t^\tau f(s, X_s^{t,x}) ds + g(\tau, X_s^{t,x}, \bar{\mu}) \right].
\]  

(5) \(g\) has the form

\[
g(t, x, \mu) = g_1(t, x)g_2(\int_{[0,T] \times \mathbb{R}} g_1(s, y)\mu(ds, dy)) + g_3(t, x),
\]

where \(g_2\) is non-increasing. There exists \(\bar{c}_g \geq 0\) and \(\beta \in [0, 1]\) such that for all \(t, t' \in [0, T], x, x' \in \mathbb{R}\),

\[
|g_1(t, x) - g_1(t', x')| \leq \bar{c}_g|t - t'| + |x - x'|,
\]

\[
|g_2(x) - g_2(x')| \leq \bar{c}_g|x - x'|,
\]

\[
|g_3(t, x) - g_3(t', x')| \leq \bar{c}_g|t - t'|^\beta + |x - x'|,
\]

(6) We assume \(g_1 \in C^{1,2}([0, T] \times \mathbb{R}), g_3 \in C^{1,2}([0, T] \times \mathbb{R})\) and \(\partial_x g_1, \partial_x g_3 \in C_b([0, T] \times \mathbb{R})\)

Moreover, for each \(t \in [0, T]\) and \(\mu \in \mathcal{P}_p([0, T] \times \mathbb{R})\),

\[
x \mapsto (f + \partial_t g + \mathcal{L}g)(t, x, \mu)
\]

is increasing. Finally, for each \(t \leq t', x \leq x'\) and \(\mu \in \mathcal{P}_p([0, T] \times \mathbb{R})\),

\[
(f + \partial_t g + \mathcal{L}g)(t', x, \mu) \leq (f + \partial_t g + \mathcal{L}g)(t, x', \mu), \quad b(t', x) \leq b(t, x).
\]

The second and third condition of Assumption 2 are easily verified under the above conditions. In the next Theorem, we prove that the first condition is also satisfied.

**Theorem D.1.** Under the Assumptions 1 and 5, for each \((\bar{\mu}, \bar{m}) \in \mathcal{R}\), there exists a unique maximizer of \(\Gamma[\bar{\mu}, \bar{m}]\) on \(\mathcal{R}\).

Proof. Fix \((\bar{\mu}, \bar{m}) \in \mathcal{R}\). Let us show that there exists a unique maximizer of \(\Gamma[\bar{\mu}, \bar{m}]\) on \(\mathcal{R}\). Under our assumptions, this map writes

\[
\Gamma[\bar{\mu}, \bar{m}](\mu, m) = \int_0^T \int_{\mathbb{R}} f(t, x)m_t(dx)dt + \int_{[0,T] \times \mathbb{R}} g(t, x, \bar{\mu})\mu(dt, dx).
\]

We characterize the maximizer via a probabilistic approach, which allows to deduce the uniqueness result. Consider a complete probability space \((\Omega, \mathcal{F}, \mathbb{P})\) supporting a Brownian motion \(W = (W_t)_{t \in [0, T]}\). Given \(t \in [0, T]\), we denote by \(\mathbb{F}^t\) the filtration given by \(\mathcal{F}^t = \sigma(W_r, t \leq r \leq s)\) for \(s \geq t\). Here \(\mathcal{N}\) is the set of \(\mathbb{P}\)-null sets and \(W_s = W_t + \mathcal{N}, s \geq t\), is the translated Brownian motion. Denote by \(T\) the set of stopping times with respect to this filtration with values in \([t, T]\). Consider the value function (to simplify the notation, we omit the dependence on \(\mu\))

\[
v(t, x) = \sup_{\tau \in T(t)} \mathbb{E} \left[ \int_t^\tau f(s, X_s^{t,x}) ds + g(\tau, X_s^{t,x}, \bar{\mu}) \right].
\]

(6.1)

where \(X_s^{t,x}\) is the unique strong solution to the SDE

\[
dX_s = b(s, X_s)ds + \sigma(X_s)dW_s; \quad X_t = x.
\]

We denote by \(\mathcal{C} = \{(t, x) \in [0, T] \times \mathbb{R} : v(t, x) > g(t, x, \bar{\mu})\}\) the continuation region, by \(\mathcal{C}^\circ\) its closure and by \(\mathcal{S} = \{(t, x) \in [0, T] \times \mathbb{R} : v(t, x) = g(t, x, \bar{\mu})\}\) the stopping region. We divide now the proof into several steps.

**First Step: Properties of the value function and optimal stopping boundary.**

Under our assumptions, it can be shown by using standard arguments that the value function \(v\) is jointly continuous. In particular, we deduce that the continuation region \(\mathcal{C}\) is an open subset of \([0, T] \times \mathbb{R}\) and that the stopping region \(\mathcal{S}\) is a closed subset of \([0, T] \times \mathbb{R}\).
Consider $x, y \in \mathbb{R}$ such that $x \leq y$ and let $t \in [0, T]$. By the comparison theorem for SDEs, we get $X_{s}^{t,x} \leq X_{s}^{t,y}$, $s \in [t, T]$. For any $\tau \in \mathcal{T}_t$, using that $z \mapsto (f + \partial_z g + Lg)(s, z, \bar{\mu})$ is increasing for each $s \in [0, T]$, a direct application of It\'s formula to $g$ gives

$$E\left[\int_t^\tau f(s, X_{s}^{t,x})\,ds + g(\tau, X_{\tau-}^{t,x}, \bar{\mu})\right] - g(t, x, \bar{\mu}) \leq E\left[\int_t^\tau f(s, X_{s}^{t,y})\,ds + g(\tau, X_{\tau-}^{t,y}, \bar{\mu})\right] - g(t, y, \bar{\mu}).$$

Taking the supremum over $\tau \in \mathcal{T}_t$, we get that, for each $t \in [0, T]$, the function $x \mapsto v(t, x) - g(t, x, \bar{\mu})$ is nondecreasing. Therefore we can define an extended real-valued function $c : [0, T] \to [-\infty, \infty]$ by $c(t) = \inf\{x \in \mathbb{R} : v(t, x) > g(t, x, \bar{\mu})\}$, if the set $\{x \in \mathbb{R} : v(t, x) > g(t, x, \bar{\mu})\}$ is non-empty and lower bounded, $c(t) = -\infty$ if the set $\{x \in \mathbb{R} : v(t, x) > g(t, x, \bar{\mu})\}$ is non-empty and not lower bounded and $c(t) = \infty$ if the set $\{x \in \mathbb{R} : v(t, x) > g(t, x, \bar{\mu})\}$ is empty. Using the continuity of $v$ and $g$, we have that for each $t$, $\{x \in \mathbb{R} : v(t, x) > g(t, x, \bar{\mu})\} = c(t), \infty\}$, allowing to deduce that

$$\mathcal{C} = \{(t, x) \in [0, T] \times \mathbb{R} : x > c(t)\}, \quad \mathcal{S} = \{(t, x) \in [0, T] \times \mathbb{R} : x \leq c(t)\}.$$ 

Since $\mathcal{S}$ is the hypograph of $c$ and it is a closed set, we deduce that $c$ is upper semicontinuous.

Consider the filtration $\mathcal{G}_t = (\mathcal{G}_t^s)_{s \in [0, T-t]}$ given by $\mathcal{G}_t^s = \mathcal{F}_{t+s}$, $s \in [0, T-t]$. We denote by $\mathcal{S}_t$ the set of stopping times with respect to this filtration with values in $[0, T-t]$. One can show that

$$v(t, x) = \sup_{\tau \in \mathcal{S}_t} E\left[\int_0^\tau f(t + s, X_{s+t}^{t,x})\,ds + g(t + \tau, X_{\tau+t}^{t,x}, \bar{\mu})\right].$$

(2.2)

Observe that, for a fixed time $t$, the stopping times in $\mathcal{S}_t$ and the process $X_{t}^{t,x}$ are functionals of the translated Brownian motion $(W_s^t)_{s \in [0, T-t]} := (W_{t+s} - W_t)_{s \in [0, T-t]}$. Since $(W_s^t)_{s \in [0, T-t]}$ and $(W_s)_{s \in [0, T-t]}$ have the same law, without loss of generality we can assume that the stopping times in $\mathcal{S}_t$ are with respect to the (completed) filtration of $W$ (we keep the same notation) and replace $X_{t}^{t,x}$ in (2.2) by the process $Y_{s}^{0,x}[t]$ which follows the dynamics

$$Y_{s}^{0,x}[t] = x + \int_0^s b(t + u, Y_{u}^{0,x}[t])\,du + \int_0^s \sigma(Y_{u}^{0,x}[t])\,dW_u.$$ 

We have $\mathcal{S}_t \subset \mathcal{S}_t$ for $t \leq t'$. Consider $t, t' \in [0, T]$ such that $t \leq t'$ and let $x \in \mathbb{R}$, we are going to show that $v(t', x) - g(t', x, \bar{\mu}) \leq v(t, x) - g(t, x, \bar{\mu})$. By the comparison theorem for SDEs, we get

$$\mathbb{P}(Y_{s}^{0,x}[t] \geq Y_{s}^{0,x}[t']$, \quad \forall s \in [0, T-t']) = 1.$$

In fact, let $b_1(s, x) = b(t+s, x)$ and $b_2(s, x) = b(t+s, x)$. For all $(s, x) \in [0, T-t'] \times \mathbb{R}$ we have $b_1(s, x) \geq b_2(s, x)$. Let $\tau'$ be an optimal stopping time for

$$v(t', x) = \sup_{\tau \in \mathcal{S}_t} E\left[\int_0^\tau f(t' + s, Y_{s}^{0,x}[t'])\,ds + g(t' + \tau, Y_{\tau}^{0,x}[t'], \bar{\mu})\right].$$

Since $\mathcal{S}_t \subset \mathcal{S}_t$, we get $\tau' \in \mathcal{S}_t$, henceforth

$$(v - g)(t', x, \bar{\mu}) - (v - g)(t, x, \bar{\mu}) \leq E\left[\int_0^\tau [(f + \partial_t g + Lg)(t' + s, Y_{s}^{0,x}[t']), \bar{\mu}) - (f + \partial_t g + Lg)(t + s, Y_{s}^{0,x}[t'], \bar{\mu})] \,ds\right] \leq 0.$$
We deduce that \( c \) is non-decreasing.

Since \( c \) is upper semicontinuous and non-decreasing, it is right-continuous. In particular, the set \( D \) of discontinuities of \( c \) is countable. The optimal stopping boundary writes

\[
\partial \mathcal{C} = \{(t, x) \in [0, T] \times \mathbb{R} : x = c(t)\} \cup \bigcup_{t \in D} (\{t\} \times [c(t-), c(t))).
\]

Since the set of discontinuities of \( c \) is countable and denoting by \( \lambda_2 \) the Lebesgue measure in \( \mathbb{R}^2 \), we get

\[
\lambda_2(\partial \mathcal{C}) \leq \lambda_2(\{x = c(t)\}) + \sum_{t \in D} \lambda_2(\{t\} \times [c(t-), c(t)]) = \int_{[0, T] \times \mathbb{R}} \mathbb{1}_{x = c(t)} \lambda_2(dt, dx)
\]

\[
= \int_0^T \lambda(\{c(t)\}) \mathbb{1}_{c(t) \in \mathbb{R}} dt = 0.
\]

Second Step: Properties of the maximizers with respect to the continuation and stopping regions.

Let \((\mu, m)\) be a maximizer of \( \Gamma[\bar{\mu}, \bar{m}] \) in \( \mathcal{R} \). We show that \( \int_\mathcal{S} m_1(dx) dt \) and \( \mu(\mathcal{C}) = 0 \). By Theorem C.6 in [24], there exist a filtered probability space \((\bar{\Omega}, \bar{\mathcal{F}}, \bar{\mathbb{P}}, \bar{\mathbb{F}})\), an \( \bar{\mathbb{F}} \)-adapted process \( \bar{X} \), an \( \bar{\mathbb{F}} \)-stopping time \( \bar{\tau} \), and an \( \bar{\mathbb{F}} \)-Brownian motion \( \bar{W} \), such that

\[
\bar{X}_t = \bar{X}_0 + \int_0^t b(s, \bar{X}_s) ds + \int_0^t \sigma(s) \bar{X}_s d\bar{W}_s, \quad \bar{\mathbb{P}} \circ \bar{X}_0^{-1} = m_0^*, \\
\mu = \bar{\mathbb{P}} \circ (\bar{\tau}, \bar{X}_\bar{\tau})^{-1}, \quad m_1(B) = \mathbb{P}^\bar{\mu}[\mathbb{1}_B(\bar{X}_t) \mathbb{1}_{0 < \bar{\tau}}], \quad B \in \mathcal{B}(\mathbb{R}), \quad t \text{ a.e.}
\]

Consider the optimal stopping problem in this probabilistic set up:

\[
\bar{v}(t, x) = \sup_{\tau \in T_t^\bar{X}} \mathbb{E}^{\bar{\mathbb{P}}}[\int_t^\tau f(s, \bar{X}_s^t, x) ds + g(\tau, \bar{X}_\tau^t, \bar{\mu})], \quad (D.3)
\]

where \( \bar{X}_s^t, x \) satisfies the SDE

\[
d\bar{X}_s = b(s, \bar{X}_s) ds + \sigma(s) d\bar{W}_s, \quad \bar{X}_t^t, x = x, \quad (D.4)
\]

and \( T_t^\bar{X} \) is the set of stopping times with respect to \( \bar{\mathbb{F}} \) and valued in \([t, T]\). By Chapter I, Section 2, Corollary 2.9 in [48], the optimal stopping time is given by

\[
\bar{\tau}_c^t, x := \inf \left\{ s \in [t, T] : \bar{v}(s, \bar{X}_s^t, x) = g(s, \bar{X}_s^t, \bar{\mu}) \right\}.
\]

By uniqueness in law of the solution of the SDE (D.4), we get \( v(t, x) = \bar{v}(t, x) \), for all \((t, x) \in [0, T] \times \mathbb{R}\). Consider the optimal stopping problem (D.3) at time 0, assuming that \( \bar{\mathbb{P}} \circ \bar{X}_0^{-1} = m_0^* \):

\[
\sup_{\tau \in T_0^\bar{X}} \mathbb{E}^{\bar{\mathbb{P}}}[\int_0^\tau f(s, \bar{X}_s) ds + g(\tau, \bar{X}_\tau, \bar{\mu})]. \quad (D.5)
\]

By measurability arguments (involving the optimal stopping time which is a measurable function of \( \bar{X} \)), we get that

\[
\int_\mathbb{R} v(0, x)m_0^*(dx) = \mathbb{E}^{\bar{\mathbb{P}}}[v(0, \bar{X}_0)] = \sup_{\tau \in T_0^\bar{X}} \mathbb{E}^{\bar{\mathbb{P}}}[\int_0^\tau f(s, \bar{X}_s) ds + g(\tau, \bar{X}_\tau, \bar{\mu})].
\]
By Theorem 2.21 in [24], we get \( \Gamma[\bar{\mu}, \bar{m}](\mu, m) = \int_{\mathbb{R}} \gamma(0, x)m_0^*(dx) \). In particular, using the probabilistic representation of \((\mu, m)\), we deduce that \( \bar{\tau} \) is an optimal stopping time for (D.5). Define the following processes

\[
U_t := v(t, \bar{X}_t) + \int_0^t f(s, \bar{X}_s)ds,
\]

\[
Z_t := \int_0^t (f + \partial_t g + Lg)(s, \bar{X}_s, \bar{\mu})ds,
\]

and

\[
\tilde{M}_t := \int_0^t \sigma(\bar{X}_s) \partial_s g(s, \bar{X}_s, \bar{\mu})d\tilde{W}_s.
\]

Observe that, since \( U \) is the Snell envelope of the process \((\int_0^t f(s, \bar{X}_s)ds + g(t, \bar{X}_t, \bar{\mu}))\) by the Doob-Meyer decomposition we get \( U_t = M_t - A_t \), where \( M \) is an \( \bar{\mathbb{F}} \)-martingale and \( A \) is a non-decreasing \( \bar{\mathbb{F}} \)-predictable process with \( A_0 = 0 \). By Theorem D.13 in [34], since

\[
\left( \int_0^t f(s, \bar{X}_s)ds + g(t, \bar{X}_t, \bar{\mu}) \right)_{t \in [0, T]}
\]

is a continuous process, we get that \( A \) is continuous (and in particular \( M \) is continuous) and

\[
\int_0^T \mathbf{1}_{\zeta_t > 0} dA_t = 0, \quad \tilde{\mathbb{P}} - \text{a.s.},
\]

where \( \zeta_t := v(t, \bar{X}_t) - g(t, \bar{X}_t, \bar{\mu}) \geq 0 \). By Tanaka’s formula,

\[
\zeta_t = \max(\zeta_t, 0) = \zeta_0 + \int_0^t \mathbf{1}_{\zeta_s > 0} d\zeta_s + \frac{1}{2} L^0_t(\zeta),
\]

where \( L^0(\zeta) \) is the local time of \( \zeta \) in 0. We deduce that

\[
\zeta_t = \zeta_0 + \int_0^t \mathbf{1}_{\zeta_s > 0} \left( U_s - Z_s - \tilde{M}_s \right) + \frac{1}{2} L^0_t(\zeta)
\]

\[
= \zeta_0 + \int_0^t \mathbf{1}_{\zeta_s > 0} dM_s - \int_0^t \mathbf{1}_{\zeta_s > 0} d\tilde{M}_s - \int_0^t \mathbf{1}_{\zeta_s > 0} dA_s - \int_0^t \mathbf{1}_{\zeta_s > 0} dZ_s + \frac{1}{2} L^0_t(\zeta)
\]

\[
= \zeta_0 + \int_0^t \mathbf{1}_{\zeta_s > 0} dM_s - \int_0^t \mathbf{1}_{\zeta_s > 0} d\tilde{M}_s - \int_0^t \mathbf{1}_{\zeta_s > 0} dZ_s + \frac{1}{2} L^0_t(\zeta).
\]

We finally get

\[
U_t = U_0 + Z_t + \tilde{M}_t + \int_0^t \mathbf{1}_{\zeta_s > 0} dM_s - \int_0^t \mathbf{1}_{\zeta_s > 0} d\tilde{M}_s - \int_0^t \mathbf{1}_{\zeta_s > 0} dZ_s + \frac{1}{2} L^0_t(\zeta)
\]

\[
= U_0 + \int_0^t \mathbf{1}_{\zeta_s > 0} dM_s + \int_0^t \mathbf{1}_{\zeta_s = 0} dM_s + \int_0^t \mathbf{1}_{\zeta_s = 0} d\tilde{M}_s + \frac{1}{2} L^0_t(\zeta).
\]

Using that

\[
\left( U_0 + \int_0^t \mathbf{1}_{\zeta_s > 0} dM_s + \int_0^t \mathbf{1}_{\zeta_s = 0} d\tilde{M}_s \right)_{t \in [0, T]}
\]
is a local martingale, by continuity of the processes and uniqueness of the semimartingale decomposition, we get

\[-A_t = \int_0^t 1_{\zeta_t = 0} dZ_s + \frac{1}{2} L^0_t(\zeta).\]

From the above, we deduce that the process

\[\int_0^t 1_{V(t, x_t) = g(t, x_t, \bar{\mu})} (f + \partial_t g + \mathcal{L} g)(t, \tilde{X}_t, \bar{\mu}) dt\]

is non-increasing. Therefore t.a.e. on \([0, T]\),

\[1_{V(t, x_t) = g(t, x_t, \bar{\mu})} (f + \partial_t g + \mathcal{L} g)(t, \tilde{X}_t, \bar{\mu}) \leq 0.\]

In particular, \((t, x) \mapsto 1_S(t, x)(f + \partial_t g + \mathcal{L} g)(t, x, \bar{\mu})\) is non-positive \(m_t(dx)\)dt-a.e. Since \(\bar{\tau}\) is optimal, \(A_{\bar{\tau}} = 0\), i.e.

\[\int_0^{\bar{\tau}} 1_{V(t, x_t) = g(t, x_t, \bar{\mu})} (f + \partial_t g + \mathcal{L} g)(t, \tilde{X}_t, \bar{\mu}) dt = -\frac{1}{2} L^0_{\bar{\tau}}(\zeta).\]

Since the Lebesgue measure of \(\partial \mathcal{C}\) is 0, by Theorem 6 in [31], we have that the local time \(L^0(\zeta)\) is indistinguishable from 0. Henceforth, taking the expectation in the last equality, we get

\[\int_S (f + \partial_t g + \mathcal{L} g)(t, x, \bar{\mu}) m_t(dx) dt = 0.\]

To simplify notation, denote by \(\nu(dt, dx) = m_t(dx) dt\) (which is absolutely continuous with respect to the Lebesgue measure in \([0, T] \times \mathbb{R}\), since \(\sigma\) satisfies the uniform ellipticity condition). Now there exists a \(\nu\)-negligible set \(N\) such that for all \((t, x) \in N^c, 1_S(t, x)(f + \partial_t g + \mathcal{L} g)(t, x, \bar{\mu}) \leq 0\). In particular, using that for all \(t \in [0, T], x \mapsto (f + \partial_t g + \mathcal{L} g)(t, x, \bar{\mu})\) is increasing, if \((t, x) \in \mathcal{S} \cap N^c, (f + \partial_t g + \mathcal{L} g)(t, x, \bar{\mu}) < 0\), where \(\mathcal{S}\) denotes the interior of \(\mathcal{S}\). Since \(\partial \mathcal{C}\) has Lebesgue measure 0, then \(\partial \mathcal{S}\) has Lebesgue measure 0 (see [4] p. 27), and we obtain

\[0 = \int_S (f + \partial_t g + \mathcal{L} g)(t, x, \bar{\mu}) \nu(dt, dx) = \int_{[0, T] \times \mathbb{R}} 1_{\mathcal{S} \cap N^c}(t, x)(f + \partial_t g + \mathcal{L} g)(t, x, \bar{\mu}) \nu(dt, dx).\]

In other words, \(\nu(\mathcal{S} \cap N^c) = 0\), which implies \(\int_\mathcal{S} m_t(dx) dt = \nu(\mathcal{S}) = \nu(\mathcal{S} \cap N^c) = 0\). Let us show now that \(\mu(\mathcal{C}) = 0\). Using the supermartingale property of \(\hat{U}\),

\[\mathbb{E}^{\bar{\tau}} \left[ \nu(\hat{\tau}, \tilde{X}_\tau) + \int_0^{\bar{\tau}} f(t, \tilde{X}_t) dt \right] \leq \mathbb{E}^{\bar{\tau}}[\nu(0, \tilde{X}_0)]\]

which implies

\[\int_{[0, T] \times \mathbb{R}} v(t, x) \mu(dt, dx) + \int_0^T \int_\mathbb{R} f(t, x) m_t(dx) dt \leq \int_\mathbb{R} v(0, x) m_0^*(dx).\]

The above inequality, together with \(v \geq g\), leads to

\[\int_{[0, T] \times \mathbb{R}} (v - g)(t, x, \bar{\mu}) \mu(dt, dx) = 0\]

and henceforth

\[0 = \int_\mathcal{C} (v - g)(t, x, \bar{\mu}) \mu(dt, dx) + \int_\mathcal{S} (v - g)(t, x, \bar{\mu}) \mu(dt, dx) = \int_\mathcal{C} (v - g)(t, x, \bar{\mu}) \mu(dt, dx).\]

Now, since \((t, x) \mapsto (v - g)(t, x, \bar{\mu}) > 0\) on \(\mathcal{C}\), we must have \(\mu(\mathcal{C}) = 0\).
Third Step: Uniqueness of the maximizer.

Assume that \((\mu^1, m^1) \in \mathcal{R}\) and \((\mu^2, m^2) \in \mathcal{R}\) are two maximizers. By the previous step, for \(i = 1, 2\), \(\int_{\mathbb{R}} m_i^t(dx)dt = 0\) and \(\mu^i(C) = 0\). By Theorem C.1 (the assumption being verified using the same ideas as in Proposition 2 of [20] with some modifications adapted to our framework), there exist, for each \(i = 1, 2\), a filtered probability space \((\bar{\Omega}, \mathcal{F}, \mathbb{F}, \mathcal{F}_t)\), an \(\mathbb{F}\)-adapted process \(X_t\) and an \(\mathbb{F}\)-Brownian motion \(W_t\) such that

\[
X_t^i = X_0^i + \int_0^t b(s, X_s^i)ds + \int_0^t \sigma(X_s^i)dW_s^i, \quad \mathbb{P}^i \circ (X_0^i)^{-1} = m^*_i,
\]

\[
\mu^i = \mathbb{P}^i \circ (\tau^i_\Theta, X^i_{\Theta})^{-1}, \quad m^*_i(B) = \mathbb{E}^2\left[\mathbb{I}_B(X^i_t)\mathbb{I}_{t < \tau^i_{\Theta}}\right], \quad B \in \mathcal{B}(\mathbb{R}), \quad t \text{ - a.e.},
\]

where \(\tau^i_{\Theta} = \inf\{t \geq 0 : (t, X^i_t) \notin \mathcal{C}\}\). By the pathwise uniqueness of the following SDE,

\[
dX_t = b(t, X_t)dt + \sigma(X_t)dW_t,
\]

we get the uniqueness in law. This implies that \(\mathbb{P}^1 \circ (X^1)^{-1} = \mathbb{P}^2 \circ (X^2)^{-1} =: P\) on \(C([0, T])\). For \(i = 1, 2\), using that \(\tau^i_{\Theta}\) is \(\sigma(X^i)\)-measurable, there exists a measurable map \(\varphi^i : C([0, T]) \rightarrow [0, T]\) such that \(\tau^i_{\Theta} = \varphi^i(X^i)\). In particular, for any bounded and measurable function \(\psi : C([0, T]) \rightarrow \mathbb{R}\), \(\mathbb{E}^2[\psi(X^1)\varphi^1(X^1)] = \mathbb{E}^2[\psi(X^2)\varphi^2(X^2)]\), that is

\[
\int_{C([0, T])} \psi(x)[\varphi^1(x) - \varphi^2(x)]P(dx) = 0.
\]

Taking \(\psi = \varphi^1 - \varphi^2\) we deduce that \(\varphi^1 = \varphi^2\) P-a.e. This is sufficient to conclude that \(m^1 = m^2\) and \(\mu^1 = \mu^2\). \(\Box\)

**Remark D.2.** Note that the above theorem gives sufficient conditions which guarantee the representation of the unique best response as a pure solution. Furthermore, the stopping time involved in the probabilistic representation is a Markov stopping time.

**Appendix E. Sufficient conditions for Assumption 4**

In this section, we provide sufficient conditions on \(b, \sigma, f, g, m^*_0\) and \(\mathcal{O}\) such that Assumption 4 is verified. We only prove the uniqueness of the best response, since it is immediate to observe that the other conditions are satisfied.

**Assumption 6.** We assume the following:

1. \(\mathcal{O}\) is a bounded open interval, \(A\) is convex and \(\sigma = 1\).
2. \(m^*_0\) admits a bounded density with respect to the Lebesgue measure.
3. \(b(t, x, a) = b_1(t, x) + b_2(t, x)a\), with \(b_1\) and \(b_2\) continuous, Lipschitz in \(x\) uniformly on \(t\) and with linear growth.
4. For all \(t \in [0, T]\), \(x \in \bar{\mathcal{O}}\), \(\eta \in \mathcal{P}^{sub}(\bar{\mathcal{O}})\), \(a \in A\), \(f(t, x, \eta, a) = f_1(t, x, \eta) + f_2(t, x, a)\). The function \(f_1\) has the form

\[
f_1(t, x, \eta) = \hat{f}(t, x)\int_{\mathcal{O}} \bar{f}(t, y)\eta(dy),
\]

where \(\hat{f}\) and \(\bar{f}\) are jointly measurable, bounded and continuous in \(x\) for each \(t\), and \(z \mapsto \bar{f}(t, z)\) is non-increasing. Moreover, there exists \(\bar{c}_f \geq 0\) such that for all \(t \in [0, T]\), \(x, x' \in \mathbb{R}\),

\[
|\hat{f}(t, x) - \hat{f}(t, x')| \leq \bar{c}_f |x - x'|, \quad |\bar{f}(t, x)| \leq \bar{c}_f (1 + |x|),
\]

\[
|\hat{f}(t, x) - \hat{f}(t, x')| \leq \bar{c}_f |x - x'|, \quad |\bar{f}(t, x)| \leq \bar{c}_f (1 + |x|).
\]

The function \(f_2\) is jointly measurable, continuous in \((x, a)\) for each \(t\), and for each \((t, x)\), \(a \mapsto f_2(t, x, a)\) is strictly concave.
(5) $g$ has the form

$$g(t, x, \mu) = g_1(t, x)g_2\left(\int_{[0, T] \times \bar{\mathcal{O}}} g_1(s, y)\mu(ds, dy)\right) + g_3(t, x),$$

where $g_1$, $g_2$, and $g_3$ are continuous and $g_2$ is non-increasing. Moreover, there exists $\bar{c}_g \geq 0$ such that for all $t, t' \in [0, T]$, $x, x' \in \mathbb{R}$,

$$|g_1(t, x) - g_1(t', x')| \leq \bar{c}_g(|t - t'| + |x - x'|), \quad |g_2(x) - g_2(x')| \leq \bar{c}_g|x - x'|.$$

Finally, for a fixed $\mu \in \mathcal{P}([0, T] \times \bar{\mathcal{O}})$, $(t, x) \mapsto g(t, x, \mu) \in C^{1,2}([0, T] \times \bar{\mathcal{O}})$ and $g(t, x, \mu) = 0$ for $(t, x) \in (0, T) \times \partial \mathcal{O}$.

Let $(\bar{\mu}, \bar{m}) \in \mathcal{R}$. Consider a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$ supporting a Brownian motion $W = (W_t)_{t \in [0, T]}$. For $t \in [0, T]$, we denote by $\mathbb{F}_t$ the filtration given by $\mathcal{F}_t = \sigma(W_r, t \leq r \leq s) \vee \mathcal{N}$, $s \geq t$. Here $\mathcal{N}$ is the set of $\mathbb{P}$-null sets and $W_s := W_s - W_t$, $s \geq t$, is the translated Brownian motion. Denote by $\mathcal{A}_t$ the set of $\mathbb{R}$-progressively measurable process with values in $\mathbb{R}$. Omitting the dependence on $\bar{m}$ and $\bar{\mu}$, consider the value function

$$v(t, x) = \sup_{\alpha \in \mathcal{A}_t} \mathbb{E}\left[\int_t^{T \wedge \tau_\mathcal{O}} f(s, X_s^{t,x,\alpha}, \bar{m}_s, \alpha_s)ds + g(T \wedge \tau_\mathcal{O}, X_T^{t,x,\alpha}, \bar{\mu})\right]. \tag{E.1}$$

where $X_s^{t,x,\alpha}$ is the unique strong solution to the SDE

$$dX_s^{t,x,\alpha} = b(s, X_s^{t,x,\alpha}, \alpha_s)ds + dW_s; \quad X_t^{t,x,\alpha} = x.$$

The following theorem is a particular case of Theorems 2.1 and 2.2, Chapter 4, in [7].

**Theorem E.1.** Let Assumptions 3 and 6 be satisfied. The value function $v$ is the unique solution belonging to $C([0, T] \times \bar{\mathcal{O}}) \cap W^{1,2}([0, T] \times \bar{\mathcal{O}})$, satisfying the following Hamilton–Jacobi–Bellman equation (HJB)

$$\frac{\partial v}{\partial t}(t, x) + \sup_{\alpha \in \mathcal{A}} [\mathcal{L}v(t, x, a) + f(t, x, \bar{m}_t, a)] = 0, \quad (t, x) \in (0, T) \times \mathcal{O},$$

$$v(t, x) = 0, \quad (t, x) \in (0, T) \times \partial \mathcal{O},$$

$$v(T, x) = g(T, x, \bar{\mu}), \quad x \in \mathcal{O}. \tag{E.2}$$

**Theorem E.2.** Under Assumptions 3 and 6, there is a unique maximizer $(\mu^*, m^*)$ of $\Gamma[\bar{\mu}, \bar{m}]$ in $\mathcal{R}$.

**Proof.** First Step: Optimality implies strict Markovian maximizer. We first prove that the set of maximizers is contained in the set of measures associated to strict controls. Let $(\mu, m) \in \mathcal{R}$ and consider the transition kernel $(\nu_t, x) \in \mathcal{P}(A)$ such that

$$m_t(dx, da)dt = \nu_t, x(da)m_t^x(dx)dt.$$

Let $D(A) = \{\delta_a : a \in A\}$ be the set of Dirac masses on $A$ which is in $\mathcal{B}(\mathcal{P}(A))$ since it is closed (recall that $A$ is compact). Consider the Borel set $B = \{(t, x) \in [0, T] \times \bar{\mathcal{O}} : \nu_t, x \in D(A)\}$. Assume that the measure $m$ is not associated to a strict control, i.e. $\int_{[0, T]} m_t^x(dx)dt > 0$, and let us show that we can construct a measure $\tilde{m}$ associated to a strict control which leads to a strictly higher reward. Define $\alpha(t, x) := \int_A a \nu_t, x(da)$ and $\tilde{m}_t(dx, da) := \delta_{\alpha(t, x)}(da)m_t^x(dx)$. The function $\alpha$ is measurable and takes values in $A$ since this set is convex and $\nu_t, x(\cdot) \in \mathcal{P}(A)$. Let $u \in C^{1,2}([0, T] \times \bar{\mathcal{O}})$, we obtain

$$\int_{\mathcal{O}} u(0, m_0^x(dx)) + \int_0^T \int_{\mathcal{O} \times \mathcal{A}} \left(\frac{\partial u}{\partial t} + \mathcal{L}u\right)(t, x, a)\tilde{m}_t(dx, da)dt$$

\[^2\text{The Sobolev space } W^{1,2}([0, T] \times \bar{\mathcal{O}}) \text{ represents the set of functions } u \text{ such that } u, \partial_t u, \partial_x u, \partial_{x^2} u \in L^2([0, T] \times \bar{\mathcal{O}}), \text{ where the derivatives are understood in the sense of distributions.}\]
Therefore, \((\mu, \tilde{m}) \in \mathcal{R}\). Now, since \(a \mapsto f(t, x, a)\) is strictly concave, by Jensen’s inequality we get
\[
\Gamma[\mu, \tilde{m}] = \int_0^T \int_{\mathcal{O} \times A} f(t, x, \tilde{m}_t, a) \nu_t(dx, da) dt + \int_{\mathcal{O}} g(t, x, \bar{\mu}) \mu(dt, dx) < \int_0^T \int_{\mathcal{O}} f(t, x, \tilde{m}_t, \alpha(t, x)) \nu_t(dx, da) dt + \int_{\mathcal{O}} g(t, x, \bar{\mu}) \mu(dt, dx) = \Gamma[\mu, \tilde{m}] = \Gamma[\mu, \tilde{m}],
\]
the inequality being strict since \(\text{supp}(\nu_t, x)\) contains more than one element on \(B^c\) and \(\int_{B^c} \tilde{m}_t^+ dx dt > 0\). We have shown that for every \((\mu, m) \in \mathcal{R}\) there exists a strict admissible control with corresponding strictly higher reward, henceforth, the set of maximizers is contained on the set of LP solutions with strict control.

**Second Step: Uniqueness of the Markovian strict control.**

Let \((\mu, m)\) be a maximizer. By Step 1, we can write
\[
m_t(dx, da) = \delta_{\alpha(t, x)}(da)m_t^\alpha(dx),
\]
for some measurable functions \(\alpha\). Using Theorem E.1 and applying an analogue proof as in Theorem 2.29 in [24] we get \(\int_0^T \int_{\mathcal{O} \times A} F_v(t, x, \tilde{m}_t, a) m_t(dx, da) dt = 0\), where
\[
F_v(t, x, \tilde{m}_t, a) := \frac{\partial v}{\partial t}(t, x) + (\mathcal{L}v)(t, x, a) + f(t, x, \tilde{m}_t, a).
\]
From the HJB equation, a.e. for all \(a \in A\), we get \(F_v(t, x, \tilde{m}_t, a) \leq 0\). We deduce that \(m_t^\alpha(dx)\)dt-a.e.,
\[
\alpha(t, x) \in \arg \max_{a \in A} \{F_v(t, x, \tilde{m}_t, a)\}.
\]
Since for each \((t, x) \in [0, T] \times \mathcal{O}\), \(b(t, x, \cdot)\) is affine and \(f(t, x, \tilde{m}_t, \cdot)\) is strictly concave, there exists a unique maximizer \(\alpha^*(t, x) \in A\) of
\[
A \ni a \mapsto F_v(t, x, \tilde{m}_t, a).
\]
Therefore we get \(\alpha(t, x) = \alpha^*(t, x)\). Without loss of generality we can assume \(\alpha = \alpha^*\) because \(\alpha^*\) is measurable (it is a particular case of Theorem 18.19 in [4]).

**Third Step: Uniqueness.**

If \((\mu^1, m^1)\) and \((\mu^2, m^2)\) are two maximizers, by the second step,
\[
m_t^k(dx, da) dt = \delta_{\alpha^*(t, x)}(m_t^{x,k}(dx) dt, \quad k = 1, 2.
\]
Now, by Theorem C.6 in [24], for \(k = 1, 2\), there exist a filtered probability space \((\Omega^k, \mathcal{F}^k, \mathbb{F}^k, \mathbb{P}^k)\), an \(\mathbb{F}^k\)-adapted process \(X^k\), an \(\mathbb{F}^k\)-Brownian motion \(W^k\) such that
\[
X_{t \wedge \tau}^k = X_0^k + \int_0^{t \wedge \tau} b(s, X_s^k, \alpha^*(s, X_s^k)) ds + W_{t \wedge \tau}^k, \quad \mathbb{P}^k \circ (X_0^k)^{-1} = m_0^k,
\]
\[
\mu^k = \mathbb{P}^k \circ (T \wedge \tau_{X_T^k}^k, X_{T \wedge \tau}^k)^{-1},
\]
By a similar proof as in Chapter 4, Proposition 3.10 in [33], we get
\[ m^k_t(B \times C) = \mathbb{E}^{p} \left[ I_B(X^k_t)I_{\alpha^*(t,X^k_t)}(C)1_{t < T_{\tau^k_0}} \right], \quad B \in \mathcal{B}(\varnothing), \quad C \in \mathcal{B}(A), \quad t \text{- a.e.} \]

Corollary E.3 (Pure solution representation of the best response). Under the Assumptions of Theorem E.2, the unique best response \((\mu^*, m^*)\) can be represented as a pure solution, i.e.
\[
\mu^* = \mathbb{P} \circ \left( X_{T \wedge \tau^X_0} \right) \left( T \wedge \tau^X_0 \right)^{-1},
\]
\[
m^*_t(B \times C) = \mathbb{E}^{p} \left[ I_B(X_t)I_{\alpha^*(t,X_t)}(C)1_{t < T_{\tau^X_0}} \right], \quad B \in \mathcal{B}(\varnothing), \quad C \in \mathcal{B}(A), \quad t \text{- a.e.}
\]

where \((\Omega, \mathcal{F}, \mathbb{P}, W)\) represents the initial probabilistic set up (see pg. 34), \(\alpha^*\) is the unique maximizer of the Hamiltonian (E.3) and \(X\) is the strong solution of the SDE associated to \(\alpha^*\).

**Appendix F. Technical Lemmas**

In this section we give analogous results to Appendix F in [24] in the case of test functions with polynomial growth.

**Lemma F.1.** Let \(X\) and \(Y\) be complete separable metric spaces and let \(\varphi : X \times Y \to \mathbb{R}\) be continuous and satisfying the following growth condition: there exist \(c \geq 0\) and \((x_0, y_0) \in X \times Y\) such that for all \((x, y) \in X \times Y\)
\[ |\varphi(x, y)| \leq c(1 + d_X(x, x_0)^p + d_Y(y, y_0)^p). \]

Consider a sequence \((\nu^n)_{n \geq 1} \in \mathcal{M}_p(X)\) converging to \(\nu \in \mathcal{M}_p(X)\) in \(\tau_p\) such that there exists \(C > 0\) so that
\[
\sup_{n \geq 1} \int_X (1 + d_X(x, x_0)^p)\nu^n(dx) \leq C.
\]

Consider also a sequence \((y^n)_{n \geq 1} \in Y\) converging to \(y \in Y\) such that there exists a compact set \(K \subset Y\) so that for all \(n \geq 1, y^n \in K\), Then,
\[
\int_X \varphi(x, y^n)\nu^n(dx) \to_{n \to \infty} \int_X \varphi(x, y)\nu(dx).
\]

The next Lemma is related to Lemma A.3 of [38].

**Lemma F.2** (Stable convergence: the \(p\)-growth case). Let \(\Theta, X, Y\) be complete, separable metric spaces. Let \(\eta \in \mathcal{M}_p(\Theta)\). Let \(\varphi : \Theta \times X \times Y \to \mathbb{R}\) be a measurable map and assume that for every \(t \in \Theta\), \(\varphi(t, \cdot, \cdot)\) is continuous. We assume the following growth condition on \(\varphi\): there exists \(c \geq 0\) and \((t_0, x_0, y_0) \in \Theta \times X \times Y\)
\[ |\varphi(t, x, y)| \leq c(1 + d_\Theta(t, t_0)^p + d_X(x, x_0)^p + d_Y(y, y_0)^p). \]

Suppose that a sequence of measurable functions \(\psi^n : \Theta \to Y\) converges \(\eta\text{-a.e.}\) in \(\Theta\) to a measurable function \(\psi : \Theta \to Y\) and that \((\nu^n_t(dx)\eta(dt))_{n \geq 1} \subset \mathcal{M}_p(\Theta \times X)\) converges to \(\nu_t(dx)\eta(dt) \in \mathcal{M}_p(\Theta \times X)\) in \(\tau_p\), where \((\nu^n)_{n \geq 1}\) and \(\nu\) are transition kernels from \(\Theta\) to \(X\). Suppose also that there exists a constant \(C > 0\) such that \(\eta\text{-a.e.}
\[
\sup_{n \geq 1} \int_X (1 + d_X(x, x_0)^p)\nu^n_t(dx) \leq C.
\]

Moreover, suppose that there exists a compact set \(K \subset Y\) such that for all \(n \geq 1, \psi^n(t) \in K\ \eta\text{-a.e.}\). Then,
\[
\int_{\Theta} \int_X \varphi(t, x, \psi^n(t))\nu^n_t(dx)\eta(dt) \to_{n \to \infty} \int_{\Theta} \int_X \varphi(t, x, \psi(t))\nu_t(dx)\eta(dt).

Please help to maintain this journal in open access!

This journal is currently published in open access under the Subscribe to Open model (S2O). We are thankful to our subscribers and supporters for making it possible to publish this journal in open access in the current year, free of charge for authors and readers.

Check with your library that it subscribes to the journal, or consider making a personal donation to the S2O programme by contacting subscribers@edpsciences.org.

More information, including a list of supporters and financial transparency reports, is available at https://edpsciences.org/en/subscribe-to-open-s2o.
