Approximating kernel functions with random features (RFs) has been a successful application of random projections for nonparametric estimation. However, performing random projections presents computational challenges for large-scale problems. Recently, a new optical hardware called Optical Processing Unit (OPU) has been developed for fast and energy-efficient computation of large-scale RFs in the analog domain. More specifically, the OPU performs the multiplication of input vectors by a large random matrix with complex-valued i.i.d. Gaussian entries, followed by the application of an element-wise squared absolute value operation – this last operation results in a dot-product kernel that has connections to the polynomial kernel, and we extend this computation to arbitrary powers of the feature map. Experiments demonstrate that the OPU kernel and its RF approximation achieve competitive performance in applications using kernel ridge regression and transfer learning for image classification. Crucially, thanks to the use of the OPU, these results are obtained with time and energy savings.

**Index Terms**— Kernel methods, nonparametric estimation, optical computing, random features, kernel ridge regression.

1. INTRODUCTION

Kernel methods represent a successful class of Machine Learning models, achieving state-of-the-art performance on a variety of tasks with theoretical guarantees [1, 2, 3]. Applying kernel methods to large-scale problems, however, poses computational challenges, and this has motivated a variety of contributions to develop them at scale; see, e.g., [2, 4, 5, 6, 7].

Consider a supervised learning task, and let \( \{x_1, \ldots, x_n\} \) be a set of \( n \) inputs with \( x_i \in \mathbb{R}^d \) associated with a set of labels \( \{t_1, \ldots, t_n\} \). In kernel methods, it is possible to establish a mapping between inputs and labels by first mapping the inputs to a high-dimensional (possibly infinite dimensional) Hilbert space \( \mathcal{H} \) using a nonlinear feature map \( \varphi : \mathbb{R}^d \rightarrow \mathcal{H} \), and then to apply the model to the transformed data. What characterizes these methods is that the mapping \( \varphi(\cdot) \) does not need to be specified and can be implicitly defined by choosing a kernel function \( k(\cdot, \cdot) \) (kernel). While kernel methods offer a flexible class of models, they do not scale well with the number \( n \) of data points in the training set, as one needs to store and perform algebraic operations with the kernel matrix \( K \), whose entries are \( K_{ij} = k(x_i, x_j) \), and which require \( O(n^2) \) storage and \( O(n^3) \) operations.

In a series of celebrated papers [8, 9], Rahimi and Recht have proposed approximation techniques of the kernel function using random features (RFs), which are based on random projections of the original features followed by the application of a nonlinear transformation. In practice, the kernel function is approximated by means of the scalar product between finite-dimensional random maps \( \varphi : \mathbb{R}^d \rightarrow \mathbb{R}^D \):

\[
k(x_i, x_j) = \langle \varphi(x_i), \varphi(x_j) \rangle_{\mathcal{H}} \approx \phi(x_i)^\top \phi(x_j) \tag{1}
\]

The RF-based approximation turns a kernel-based model into a linear model with a new set of nonlinear features \( \phi(x) \); as a result, the computational complexity is reduced from \( O(n^3) \) to \( O(ndD + O(D^2)) \) to construct the random features and \( O(D^3) \) to optimize the linear model, where \( D \) is the RF dimension and \( n \) the number of data points. Furthermore, there is no need to allocate the kernel matrix, reducing the storage from \( O(n^2) \) to \( O(nD) + O(D^2) \). Unless approximation strategies to compute random features are used, e.g., [10], computing RFs is one of the main computational bottlenecks.

A completely different approach was pioneered in Saade et al. [11], where the random projections are instead made via an analog optical device – the Optical Processing Unit (OPU) – that performs these random projections literally at the speed of light and without having to store the random
matrix in memory. Their results demonstrate that the OPU makes a significant contribution towards making kernel methods more practical for large-scale applications with the potential to drastically decrease computation time and memory, as well as power consumption. The OPU has also been applied to other frameworks like reservoir computing [12, 13] and anomaly detection [14].

Building on the milestone work of [11], the goal of the present contribution is threefold: a) we derive in full generality the kernel to which the dot product computed by the OPU RFs converges, generalizing the earlier computation of [11] to a larger class of kernels; b) we present new examples and a benchmark of applications for the kernel of the OPU; and c) we give a detailed comparison of the running time and energy consumption between the OPU and a last generation GPU.

## 2. THE OPTICAL PROCESSING UNIT

The principle of the random projections performed by the Optical Processing Unit (OPU) is based on the use of a heterogeneous material that scatters the light that goes through it, as shown in Fig. 1 for the experimental setup. The data vector \( \mathbf{x} \in \mathbb{R}^d \) is encoded into light using a digital micromirror device (DMD). This encoded light then passes through the heterogeneous medium, performing the random matrix multiplication. As discussed in [15], light going through the scattering medium follows many extremely complex paths, that depend on refractive index inhomogeneities at random positions. For a fixed scattering medium, the resulting process is still linear, deterministic, and reproducible. Reproducibility is important as all our data vectors need to be multiplied by the same realisation of the random matrix.

After going through the "random" medium, we observe a speckle figure on the camera, where the light intensity at each point is modelled by a sum of the components of \( \mathbf{x} \) weighted by random coefficients. Measuring the intensity of light induces a non-linear transformation of this sum, leading to:

### Proposition 1

Given a data vector \( \mathbf{x} \in \mathbb{R}^d \), the random feature map performed by the Optical Processing Unit is:

\[
\phi(\mathbf{x}) = \frac{1}{\sqrt{D}} |\mathbf{U}\mathbf{x}|^2
\]

where \( \mathbf{U} \in \mathbb{C}^{D \times d} \) is a complex Gaussian random matrix whose elements \( U_{ij} \sim \mathcal{CN}(0, 1) \), the variance being set to one without loss of generality, and depends on a multiplicative factor combining laser power and attenuation of the optical system. We will name these RFs optical random features.

## 3. COMPUTING THE KERNEL

When we map two data points \( \mathbf{x}, \mathbf{y} \in \mathbb{R}^d \) into a feature space of dimension \( D \) using the optical RFs of Eq. 2, we have to compute the following to obtain the associated kernel \( k_2 \):

\[
k_2(\mathbf{x}, \mathbf{y}) \approx \phi(\mathbf{x})^\top \phi(\mathbf{y}) = \frac{1}{D} \sum_{j=1}^{D} |\mathbf{x}^\top \mathbf{u}(j)|^2 |\mathbf{y}^\top \mathbf{u}(j)|^2
\]

\[
D \rightarrow +\infty \int |\mathbf{x}^\top \mathbf{u}|^2 |\mathbf{y}^\top \mathbf{u}|^2 \mu(\mathbf{u}) \, d\mathbf{u}
\]

with \( \mathbf{U} = [\mathbf{u}^{(1)}, \ldots, \mathbf{u}^{(D)}]^\top \) and \( \mathbf{u}^{(j)} \in \mathbb{R}^d, \forall j \in \{1, \ldots, D\} \).

### Theorem 1

The kernel \( k_2 \) approximated by the dot product of optical random features of Eq. 2 is given by:

\[
k_2(\mathbf{x}, \mathbf{y}) = ||\mathbf{x}||^2 ||\mathbf{y}||^2 + (\mathbf{x}^\top \mathbf{y})^2
\]

where the norm is the \( l_2 \) norm.

### Proof

By rotational invariance of the complex Gaussian distribution, we can fix \( \mathbf{x} = ||\mathbf{x}|| \mathbf{e}_1 \) and \( \mathbf{y} = ||\mathbf{y}|| (\mathbf{e}_1 \cos \theta + \mathbf{e}_2 \sin \theta) \), with \( \theta \) being the angle between \( \mathbf{x} \) and \( \mathbf{y} \), \( \mathbf{e}_1 \) and \( \mathbf{e}_2 \) being two orthonormal vectors. Letting \( \mathbf{e}_1^\top \mathbf{u} = u_1 \sim \mathcal{CN}(0, 1), i = 1, 2 \) and \( u_1^* \) be the complex conjugate of \( u_1 \), we obtain:

\[
k_2(\mathbf{x}, \mathbf{y}) = ||\mathbf{x}||^2 ||\mathbf{y}||^2 \int |u_1|^2 |u_1 \cos \theta + u_2 \sin \theta|^2 \mu(\mathbf{u})
\]

\[
= ||\mathbf{x}||^2 ||\mathbf{y}||^2 \int \left( |u_1|^4 \cos^2 \theta + |u_1|^2 |u_2|^2 \sin^2 \theta + 2 |u_1|^2 \text{Re}(u_1^* u_2) \cos \theta \sin \theta \right) \mu(\mathbf{u}) \, d\mathbf{u}
\]

By a parity argument, the third term in the integral vanishes, and the remaining ones can be explicitly computed, yielding:

\[
k_2(\mathbf{x}, \mathbf{y}) = ||\mathbf{x}||^2 ||\mathbf{y}||^2 (1 + \cos^2 \theta) = ||\mathbf{x}||^2 ||\mathbf{y}||^2 + (\mathbf{x}^\top \mathbf{y})^2
\]

Numerically, one can change the exponent of the feature map to \( m \in \mathbb{R}^+ \), which, using notations of Eq. 2, becomes:

\[
\phi(\mathbf{x}) = \frac{1}{\sqrt{D}} |\mathbf{U}\mathbf{x}|^m
\]
Theorem 2. When the exponent \( m \) is even, i.e. \( m = 2s \), \( \forall s \in \mathbb{N} \), the dot product of feature maps of Eq. 6 tends to the kernel \( k_{2s} \) (for \( D \to \infty \)):

\[
k_{2s}(x, y) = \|x\|^m \|y\|^m \sum_{i=0}^{s} (s!2^i) \left( \frac{x^\top y}{\|x\|^2 \|y\|^2} \right)^{2i}
\]

Moreover, a generalization \( \forall m \in \mathbb{R}^+ \) can be established.

Eq. 7 is connected to the polynomial kernel defined as:

\[
(\nu + x^\top y)^p = \sum_{i=0}^{p} \binom{p}{i} \nu^{p-i} (x^\top y)^i
\]

with \( \nu \geq 0 \) and \( p \in \mathbb{N} \) the order of the kernel. For \( \nu = 0 \) the kernel is called homogeneous. For \( \nu > 0 \) the polynomial kernel consists of a sum of lower order homogeneous polynomial kernels up to order \( p \). It can be seen as having richer feature vectors including all lower-order kernel features. For optical RFs raised to the power of \( s \in \mathbb{N} \) we have a sum of homogeneous polynomial kernels taken to even orders up to \( m = 2s \).

Since \( x^\top y = \|x\| \|y\| \cos \theta \), the kernel scales with \( \|x\| \|y\| \), which is characteristic to any homogeneous polynomial kernel. It is easy to extend this relation to the inhomogeneous polynomial kernel by appending a bias to the input vectors, i.e. \( x' = x + \sqrt{r}x \) when \( x' = (\sqrt{r}, x_1, ..., x_d)^\top \) and \( y' = (\sqrt{r}, y_1, ..., y_d)^\top \). A practical drawback of this approach is that increasing the power of the optical RFs also increases their variance. Thus, convergence requires higher projection dimensions. Although high dimensional projections can be computed easily using the OPU, solving models on top of them poses other challenges that require special treatment (e.g. Ridge Regression scales cubically with \( D \)). Therefore, we did not include these cases in the experiments in the next section and leave them for future research.

4. EXPERIMENTS

In this section, we assess the usefulness of optical RFs for different settings and datasets. The model of our choice in each case is Ridge Regression. OPU experiments were performed remotely on the OPU prototype "Vulcain", running in the LightOn Cloud with library LightOnOPU v1.0.2. Since the current version only supports binary input data we decide to binarize inputs for all experiments using a threshold binarizer. The code of the experiments is publicly available.\(^1\)

4.1. Optical random features for Fashion MNIST

We compare optical RFs (simulated as well as physical) to an RBF Fourier Features baseline for different projection dimensions \( D \) on Fashion MNIST. We use individually optimized hyperparameters for all RFs that are found for \( D = 5000 \) using an extensive grid search on a held-out validation set.

**4.3. Projection time and energy consumption**

The main advantage of the OPU compared to a traditional CPU/GPU setup is that the OPU takes a constant time for computing RFs of arbitrary dimension $D$ (up to $D = 10^6$ on current hardware) for a single input. Moreover, its power consumption stays below 30 W independently of the workload. Fig. 3 shows the computation time and the energy consumption over time for GPU and OPU for different projection dimensions $D$. In both cases, the time and energy spending do not include matrix building and loading. For the GPU, only the calls to the PyTorch function `torch.matmul` are measured and energy consumption is the integration over time of power values given by the command `nvidia-smi`.

For the OPU, the energy consumption is constant w.r.t. $D$ and equal to 45 Joules (30 W multiplied by 1.5 seconds). The GPU computation time and energy consumption are monotonically increasing except for an irregular energy development between $D = 45 000$ and $D = 56 000$. This exact irregularity was observed throughout all simulations we performed and can most likely be attributed to an optimization routine that the GPU carries out internally. The OPU is up to 7 times more energy efficient than the GPU for large random projections. The GPU starts to use more energy than the OPU from $D = 18 000$ and runs out of memory for $D = 58 000$. The exact crossover points may change in future hardware versions. The relevant point we make here is that the OPU has a better scalability in $D$ with respect to computation time and energy consumption.

**Conclusion and perspectives**

The increasing size of available data and the benefit of working in high-dimensional spaces led to an emerging need for dedicated hardware. GPUs have been used with great success to accelerate algebraic computations for kernel methods and deep learning. Yet, they rely on finite memory, consume large amounts of energy and are very expensive.

In contrast, the OPU is a scalable memory-less hardware with reduced power consumption. In this paper, we showed that optical RFs are useful in their natural form and can be modified to yield more flexible kernels. In the future, algorithms should be developed to deal with large-scale RFs, and other classes of kernels and applications should be obtained using optical RFs.

### Table 1: Test errors (in %) on CIFAR-10 using $D = 10^4$ RFs for each kernel (except linear). Features were extracted from intermediate layers when using the original input size (32x32). Final convolutional layers were used with upscaled inputs (224x224). $L(i)$ refers to the ith ResNet34 layer and MP(i) to the ith MaxPool layer of VGG16/AlexNet. Values for the kernel limit are shown in parenthesis (last column).

| Architecture | ResNet34 | AlexNet | VGG16 |
|--------------|---------|---------|-------|
| Layer        | L1      | L2      | L3    | Final | MP1 | MP2 | Final | MP2 | MP3 | MP4 | MP5 | Final |
| Dimension $d$| 4 096   | 2 048   | 1 024 | 512   | 576 | 192 | 9 216 | 8 192 | 4 096 | 2 048 | 512 | 25 088 |
| Sim. Opt. RFs| 30.4    | 24.7    | 28.9  | 11.6  | 38.1 | 41.9 | 19.6  | 28.2 | 20.5 | 20.7 | 29.8 | 15.2 (12.9) |
| Optical RFs  | 31.1    | 25.7    | 29.7  | 12.3  | 39.2 | 42.6 | 20.8  | 30.9 | 23.3 | 21.5 | 30.2 | 16.4 |
