(Dated: November 16, 2005)

Encouraged by the latest SNO results, we consider the lepton mixing matrix in the approximation that the ν2 mass eigenstate is trimaximally (democratically) mixed. This suggests a new parameterization of the remaining mixing degrees of freedom, which eschews mixing angles, dealing instead, directly with the complex parameter Ue3 of the mixing matrix. Unitarity triangles then take a particularly simple form, which we hope will facilitate comparison with experiment.

Recent years have seen huge advances in our knowledge of the properties of neutrinos. Most recently, SNO [1, 2] has provided the best evidence for neutrino flavour change, which, coupled with evidence from atmospheric neutrinos [3, 4], reactors [5–7] and accelerator experiments [8], has enabled the basic form of the MNS [9] lepton mixing matrix, U, to be determined [10].

Atmospheric neutrino data [3, 4], together with K2K [8] and reactor data [5, 6], give (at 68% CL)[10]:

\[ |U_{e3}|^2 \lesssim 0.012 \quad |U_{\mu 3}|^2 = 0.50 \pm 0.11. \]  
(1)

Therefore \( |U_{\tau 3}|^2 \approx 0.50 \pm 0.11 \), implying that

\[ |U_{e3}|^2 \approx 0 \quad |U_{\mu 3}| \approx |U_{\tau 3}| \approx \frac{1}{\sqrt{2}}. \]  
(2)

We may choose the phases of \( \nu_\mu \) and \( \nu_\tau \) such that to a good approximation

\[ \nu_3 = \frac{1}{\sqrt{2}}(\nu_\mu - \nu_\tau). \]  
(3)

Unitarity then implies that, with the above choice of phases,

\[ U_{\mu 2} \approx U_{\tau 2} \quad U_{\mu 1} \approx U_{\tau 1}, \]  
(4)

ie. approximate \( \mu-\tau \) symmetry [11–13]. From the analysis of solar neutrino data [14–18], especially from SNO [1, 2], we have (at 68% CL):

\[ |U_{e2}|^2 = 0.31 \pm 0.04 \]  
(5)

implying

\[ |U_{e2}| \approx |U_{\mu 2}| \approx |U_{\tau 2}| \approx \frac{1}{\sqrt{3}}. \]  
(6)

The phases of \( \nu_2 \) and \( \nu_e \) can be chosen such that

\[ \nu_2 = \frac{1}{\sqrt{3}}(\nu_e + \nu_\mu + \nu_\tau). \]  
(7)

Unitarity now fixes the remaining three MNS matrix elements up to their overall phase, which may be chosen so that

\[ \nu_1 = \frac{1}{\sqrt{6}}(2\nu_e - \nu_\tau - \nu_\mu). \]  
(8)

Both the relative precision, and the absolute precision, in the determination of \( |U_{e2}|^2 \) in Eq. (5) is better than that of \( |U_{\mu 3}|^2 \) in Eq. (1), making \( |U_{e2}| \approx \frac{1}{\sqrt{3}} \) currently the best-determined of the MNS matrix elements.

Equations (3), (7) and (8) together define the trimaximal mixing texture [19–21], which we may take to be the leading approximation to the lepton mixing matrix. This texture is clearly evocative of symmetries at work. Taking the neutrino flavour eigenstates to define the orientation of a cube, the \( \nu_2 \) eigenstate, Eq. (7), lies on the body diagonal of the cube, while the \( \nu_1 \) mass eigenstate lies in the plane of the \( \nu_\mu - \nu_\tau \) face, at 45° to the \( \nu_\mu \) state. It may be remarked that the same mixing matrix elements also occur as the \( M = 0 \) subset of the \( j \times j = 1 \times 1 \) set of Clebsch-Gordan coefficients.

An extensive future experimental neutrino program is being planned [22–24] which will refine the trimaximal picture outlined above. The current situation for neutrino physics and the MNS matrix appears analogous to that earlier for \( B \) physics and the CKM matrix, in which the leading approximation to the matrix was established experimentally, long before its smallest elements were determined. In that case, the Wolfenstein parametrization has become widely adopted [25]. This approximate parameterization avoids the introduction of mixing angles, dealing instead directly with the complex elements of the matrix, with the help of “unitarity triangles” [26–33]. It is our purpose here to propose an analogously simple parameterization for the MNS mixing in the lepton sector. It is motivated by the phenomenological success of trimaximal mixing, which it takes as a starting point, but does not in fact depend upon this mixing form being exact, or even theoretically consequential.
In the CKM case, phases are chosen such that the diagonal elements, as well as the two elements in the row above the diagonal, are chosen real and positive. Then unitarity controls the remaining elements, with the free variable of greatest importance being $V_{ub}$. The values of the two elements in the row below the diagonal are insensitive to details, while the remaining one, $V_{td}$, is related to $V_{ub}$ via the well-known unitarity triangle.

For the case of the MNS matrix, the optimal choice of phases is different because the mixing pattern is different. The most striking feature of the data is arguably the near-democratic mixing of the $\nu_2$ mass eigenstate, as expressed in Eq. (6). As we show later, even for subdominant oscillation phenomena, it is a robust approximation to assume exact trimaximal mixing for the $\nu_2$ column. A natural choice of phases is then to require the $\nu_2$ column to be real and positive. The remaining elements are then controlled by $U_{e3}$ (the analogue of $V_{ub}$), which is again small, and again vital to the unresolved issue of CP violation, this time within the lepton sector.

We construct a generalisation of the tribimaximal form, consistent with the above considerations:

$$U \simeq \begin{pmatrix} \frac{2}{\sqrt{3}} & \frac{1}{\sqrt{3}} & 0 \\ -\frac{1}{\sqrt{6}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{6}} & -\frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{2}} \end{pmatrix} \begin{pmatrix} C & 0 & \sqrt{\frac{2}{3}} U_{e3} \\ 0 & 1 & 0 \\ -\sqrt{\frac{2}{3}} U_{e3}^* & 0 & C \end{pmatrix},$$

$$U \simeq \begin{pmatrix} \frac{2}{\sqrt{3}} C & \frac{1}{\sqrt{3}} U_{e3} & \frac{1}{\sqrt{2}} U_{e3} \\ -\frac{1}{\sqrt{6}} C - \frac{\sqrt{2}}{\sqrt{3}} U_{e3}^* & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} C - \frac{1}{2} U_{e3} \\ -\frac{1}{\sqrt{6}} C + \frac{\sqrt{2}}{\sqrt{3}} U_{e3}^* & \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{2}} C - \frac{1}{2} U_{e3} \end{pmatrix}$$

where

$$C = \sqrt{1 - \frac{3}{2} |U_{e3}|^2} \simeq 1.$$ (10)

The matrix in Eq. (9) is exactly unitary, by construction. The need for the factor $\sqrt{\frac{1}{2}}$ in the second matrix in the expansion of Eq. (9) is to keep $U_{e3}$ itself as the operative parameter in the resulting product. Dropping terms of order $|U_{e3}|^2$ for simplicity (ie. setting $C = 1$), we obtain the approximation

$$U \simeq \begin{pmatrix} \frac{2}{\sqrt{3}} & \frac{1}{\sqrt{3}} U_{e3} & \frac{1}{\sqrt{2}} U_{e3} \\ -\frac{1}{\sqrt{6}} + \frac{\sqrt{2}}{\sqrt{3}} U_{e3}^* & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} - \frac{1}{2} U_{e3} \\ -\frac{1}{\sqrt{6}} - \frac{\sqrt{2}}{\sqrt{3}} U_{e3}^* & \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{2}} - \frac{1}{2} U_{e3} \end{pmatrix}.$$ (11)

In our parameterization, $|U_{e3}|$ corresponds exactly to the same quantity in the standard (PDG) parameterization [34]:

$$|U_{e3}| = \sin \theta_{13},$$ (12)

while our phase convention for $U_{e3}$ differs only slightly from the usual one. This phase is fixed by the construction in Eq. (9) such that $\delta' \equiv -\text{Arg}(U_{e3})$ is given by

$$\sin \delta' = \sin \theta_{23} \sin \delta$$

$$\simeq \sin \delta$$ (13) (14)

which explains our choice of sign for the $\nu_3$ column. Exact equivalence of these two phase definitions is obtained for the two special cases given by either $\text{Re}(U_{e3}) = 0$ or $\text{Im}(U_{e3}) = 0$.

CP violation is, of course, governed by $\text{Im}(U_{e3})$. We have for Jarlskog’s CP-violating observable [35, 36]:

$$J_{CP} = \frac{C \text{Im}(U_{e3})}{3\sqrt{2}} \simeq \frac{\text{Im}(U_{e3})}{3\sqrt{2}}.$$ (15)

The parameter $\text{Re}(U_{e3})$ violates $\mu-\tau$ reflection symmetry (simultaneous interchange of $\mu$ and $\tau$ flavour labels and a CP transformation [12]).

For the CP-violating case, unitarity triangles [26–33] may be constructed in the usual way, using the orthogonality of pairs of columns (or rows) of the mixing matrix. With our parameterization, Eqs. (9)-(11), most of the triangles become especially simple. A particular example is the “$\nu_2,\nu_3$” triangle shown in Fig. 1, which expresses the orthogonality of the $\nu_2$ and $\nu_3$ mass eigenstates (the dashed line bisects the $\nu_3$ side, is real and has length $\frac{1}{\sqrt{3}} C$). The triangle has been scaled by a factor $\sqrt{3}$ so that the sides are equal to the components of the $\nu_3$ column of the lepton mixing matrix. The error-ellipse indicates the allowed range of $|U_{e3}|$; the vertical error is given by the reactor bound [5, 6], while the horizontal error was obtained by combining this with the implied constraint from the experimental value of $|U_{e3}|$ (Eq. (1)). under the assumption of exact trimaximal mixing of the $\nu_2$ mass eigenstate.

![LEPTONIC UNITARITY TRIANGLE: $V_2 \cdot V_3$ (SCALED x 3)](image_url)

**FIG. 1:** The “$\nu_2,\nu_3$” unitarity triangle representing the orthogonality of the $\nu_2$ and $\nu_3$ mass eigenstates (the dashed line bisects the $\nu_3$ side, is real and has length $\frac{1}{\sqrt{3}} C$). The triangle has been scaled by a factor $\sqrt{3}$ so that the sides are equal to the components of the $\nu_3$ column of the lepton mixing matrix. The error-ellipse indicates the allowed range of $|U_{e3}|$; the vertical error is given by the reactor bound [5, 6], while the horizontal error was obtained by combining this with the implied constraint from the experimental value of $|U_{e3}|$ (Eq. (1)). under the assumption of exact trimaximal mixing of the $\nu_2$ mass eigenstate.
to the elements of the $\nu_1$ mass eigenstate. It may be con-
structed from a (real) line of length $U_{e1} = \frac{\sqrt{2}}{\sqrt{3}} C$, bisected
by a (complex) line given by $\frac{\sqrt{2}}{2} U_{e3}$ whose end defines
the third vertex. The triangle expressing the orthogo-
nality of the $\nu_1$ and $\nu_2$ columns is the least degenerate
of the three column-based triangles, but has no special
simplification, in general, here.

The three triangles representing orthogonality of the
rows of the MNS matrix are now similarly determined
entirely in terms of $U_{e3}$. They each share one angle with
each of the column-wise triangles. Note that with $\nu_2$
exactly trimaximally mixed each of these row-based tri-
angles stands on a common real base of length $\frac{1}{4}$, which
could be rescaled to unity if desired.

Of course, the rephasing invariance of observables means
that only the triangles’ opening angles, side-
lengths, and areas have physical significance (see below),
their orientation being irrelevant. Symmetries are re-

deflected in the shapes of the triangles, eg. with exact $\mu$-$\tau$
reflection symmetry, all three column-based triangles are
isosceles (their sides carry lepton flavour indices), while
the $\epsilon$,$\tau$ and $\epsilon$,$\mu$ triangles become congruent to each other.
If $CP$ is conserved, each triangle is reduced to a line.

We turn now to the use of the triangles in thephe-
nomenology of leptons, especially neutrino oscillations.
The sides of the row-based triangles are given by com-
plex products of MNS matrix elements, $U_{\alpha i} U^*_\beta j$, where
the flavour labels $\alpha$ and $\beta$ define the triangle, and
the mass index $i$, labels the side. These triangle sides are the (complex)
magnitudes of the three sub-amplitudes
which mediate neutrino oscillations between flavour $\alpha$
and flavour $\beta$, one for each neutrino mass eigenstate, $i$:

$$|A(\nu_\alpha \rightarrow \nu_\beta)| = \sum_{i=1,3} U_{\alpha i} U^*_{\beta i} e^{(-i m_i^2 L/2E)}$$

$$= 2 |U_{\alpha 1} U^*_{\beta 1} \sin \Delta_{1k} + U_{\alpha j} U^*_{\beta j} \sin \Delta_{jk} e^{i\phi_{jk}}|$$

$$(\alpha \neq \beta, i \neq j \neq k), \text{where } \Delta_{ij} \equiv (m_i^2 - m_j^2) L/4E, \text{L is the propagation distance, } E \text{ is the neutrino en}-$$

ergy and $m_i$ is the mass of $\nu_i$. Squaring Eq. (16) to
obtain appearance probabilities, we see that the trian-
gles’ side-lengths, $|U_{\alpha i} U^*_{\beta i}|$, and their opening angles,
$\phi_{\gamma k} \equiv \text{Arg}(U_{\alpha i} U^*_{\beta i} U_{\alpha j}^* U^*_{\beta j})$, ($\gamma \neq \alpha \text{ etc.})[41]$, appear ex-
plicitly (see eg. Eq (21) below). With our parameteriza-
tion, $U_{\alpha 2} U^*_{\beta 2} = 1/3$ for all flavour-pairs, $\alpha, \beta$, while other
side-lengths become simple functions of $U_{e3}$.

The $CP$ parameter, $J_{CP} = |U_{\alpha i} U^*_{\beta 1}| |U_{\alpha j} U^*_{\beta j}| \sin \phi_{\gamma k}$, $\forall \gamma, k$, equals twice the area of each (un-rescaled) triangle.
For the triangle in Fig. 1, we find using Eq. (15):

$$\sin \phi_{\alpha 1} = \frac{C \text{ Im}(U_{e3})}{\sqrt{2} |U_{\beta 3}| |U_{\gamma 3}|} \approx \frac{\text{ Im}(U_{e3})}{\sqrt{2} |U_{\beta 3}| |U_{\gamma 3}|}$$

with $\alpha \neq \beta \neq \gamma$. Expressions may similarly be obtained
for the angles of all the other triangles.

Expressions for neutrino oscillation survival probabili-
ties involve directly the moduli-squared of MNS matrix

elements, $|U_{\alpha i}|^2$. Here again, $|U_{\alpha 1}|^2 = 1/3$ for all

flavours $\alpha$. For $i = 3$, these are the side lengths of the $\nu_2, \nu_3$
triangle of Fig. 1 which (for the non-trivial cases) are given
in terms of $U_{e 3}$ by:

$$|U_{\alpha 3}|^2 = \frac{1}{2} - \frac{|U_{\alpha 1}|^2}{2} + \frac{C \text{ Re}(U_{e 3})}{\sqrt{2}}$$

$$\approx \frac{1}{2} \pm \frac{\text{ Re}(U_{e 3})}{\sqrt{2}},$$

where the upper(lower) signs correspond to $\alpha = \mu(\tau),\text{ respectively (the approximate form may be obtained di-
rectly by inspection of Fig. 1). The analogous result for}

$i = 1$ is obtained from the $\nu_1, \nu_2$ triangle as:

$$|U_{\alpha 1}|^2 = \frac{1}{6} + \frac{|U_{\alpha 3}|^2}{2} \pm \frac{C \text{ Re}(U_{e 3})}{\sqrt{2}}$$

$$\approx \frac{1}{6} \pm \frac{\text{ Re}(U_{e 3})}{\sqrt{2}}.\quad (19)$$

A new generation of experiments is being planned and
built to address the question of non-leading neutrino os-
cillations [22–24]. The description of the observables at
these new experiments is usefully presented as a series
expansion [37] in the two small quantities:

$$\alpha = \frac{\Delta_{31}}{\Delta_{21}} \approx 0.026, \quad 0.021 \lesssim \alpha \lesssim 0.036 \quad (90\% \text{ CL}),\quad (20)$$

(describing the hierarchy of mass-squared differences),
and $|U_{e 3}| = \sin \theta_{13} \lesssim 0.17$ (90% CL), as a function of the
standard parameters. In terms of our parameterization,
we find a considerable simplification. To leading (second)
order in small quantities, the $\nu_e$ appearance probability
in a long baseline muon neutrino beam is (in vacuum):

$$P(\nu_\mu \rightarrow \nu_e) \approx 2 |U_{e 3}|^2 \sin^2 \Delta_{31} + \frac{4}{9} \alpha^2 \Delta_{31}^2 + \frac{8 \alpha |U_{e 3}|}{3 \sqrt{2}} \Delta_{31} \sin \Delta_{31} \cos (\Delta_{31} + \delta')$$

(21)

where the $CP$-violating phase $\delta' \approx \delta \approx \phi_{+1}$ at this or-
der of approximation (see Fig. 1 and Eqs. (13)-(14)).
The electron anti-neutrino disappearance probability at a (not too distant) reactor experiment is given, again to leading (second) order in small quantities, by:

\[ 1 - P(\bar{\nu}_e \to \bar{\nu}_e) \simeq 4|U_{e3}|^2 \sin^2 \Delta_{31} + \frac{8}{9} \alpha^2 \Delta_{31}^2. \] (22)

Although Eqs. (21) and (22) have been derived under the assumption of exact trimaximal mixing of the $\nu_2$ mass eigenstate, it can be shown that they are still valid at second order in small quantities, even in the case that this assumption is broken by small perturbations. This justifies our proposal of Eq. (11) as a viable approximate parameterization of the MNS matrix.

As well as oscillation phenomenology, the row-based triangles play a role in (lepton number violating) radiative decays of charged leptons, while the column-based ones play an analogous role in radiative decays of neutrinos, although admittedly, these are unlikely to play a major role in phenomenology, as they are all highly suppressed in the Standard Model [38].

Clearly, neutrino oscillation experiments have come a long way since one could countenance the idea of trimaximal mixing for all three neutrino species [19, 39, 40]. There is today however, still the real prospect that one neutrino mass eigenstate, $\nu_2$, is indeed trimaximally mixed, and this hints at deeper symmetries beyond the Standard Model. While it is important to test experimentally whether the $\nu_2$ mass eigenstate is exactly trimaximally mixed, we have argued that this assumption at least serves as a useful simplification and as a starting-point in parameterizing the other open questions about the lepton mixing matrix.

This work was supported by the UK Particle Physics and Astronomy Research Council (PPARC), and in part, by the US. Department of Energy contract DE-AC02-76SF00515. Two of us (PFH and JDB) acknowledge the hospitality of the Centre for Fundamental Physics (CIFP) at CCLRC Rutherford Appleton Laboratory.
