Abstract
It is quite important to develop the microorganism resources with biocontrol capacity for rice blast. This study evaluated Bacillus subtilis JN005 for growth promotion and biocontrol efficacy against Magnaporthe oryzae. Results showed that rice seeds treated with 1 × 10⁷ cfu/mL suspension of B. subtilis JN005 had 16% germination energy, 14% germination rate, 15% germination index, and 270% vigor index compared to those treated with sterile water (control). In pot experiments, the JN005 strain-treated rice plants exhibited notable increase in plant height, root length, stem circumference, and fresh weight, as well as higher concentration of chlorophyll a, chlorophyll b, and total chlorophyll in rice leaves. Rice leaves inoculated with the JN005 strain resulted in increased activities of defense-related enzymes, including peroxidase (POD), phenylalanine ammonialyase (PAL), superoxide dismutase (SOD), and catalase (CAT) compared to the water and the M. oryzae-inoculated treatments. In vitro inoculated rice leaves with 1 × 10⁷ cfu/mL bacterial suspension compared to sterile water or control treatment exhibited lower disease incidence in the curative and preventive groups by 79% and 76%, respectively. Field experiment showed that after spraying with 1 × 10⁷ cfu/mL bacterial suspension, efficacy rates on controlling rice blast on plants were (56.82 ± 1.12)% and (58.39 ± 3.05)% at seedling and maturity stages, respectively, and that rice production yield was (524.40 ± 17.88) g/m². Therefore, B. subtilis JN005 could be a promising biological control agent for rice blast, thereby warranting further investigation of its efficacy.

Keywords Bacillus subtilis · Rice · Magnaporthe oryzae · Biological control

Introduction
Rice blast caused by the Magnaporthe oryzae is one of the most destructive plant diseases, effecting 10% to 30% annual global rice output loss (Asibi et al. 2019) that may result in severe economic and humanitarian issues (Miah et al. 2017). Although agrochemicals enable quick and effective control of plant diseases, their excessive use increases the potential of resistance buildup in plant pathogens (Wang and Cernava 2020; Majeed 2018). In recent years, some promising and eco-friendly alternatives to chemical control have been developed to curtail plant diseases (Barratt et al. 2018; Emoghene and Futughe 2016). The use of biological control agents has become a trend owing to global development orientations on use of non-chemical alternatives with less negative impact to the environment.

Recent studies have identified bacterial groups as biocontrol agents against plant pathogens that mainly include Pseudomonas spp. and Bacillus spp. (Chen et al. 2020; Sun et al. 2017). Bacillus spp. are gram-positive, rod-shaped, endospore-forming bacteria that have potential to produce diverse bioactive compounds and ability to produce endospores, therefore make them preferable candidates for commercial exploitation as bacterial biocontrol agents (Sowanpreecha et al. 2018; Jangir et al. 2018). To date, 26 microbiological preparations to control rice blast in China have been newly registered (http://
www.icama.org.cn/hysj/index.jhtml) that are composed of 22 *B. subtilis*, 3 *B. cereus*, and 1 *B. amyloliquefaciens* strains and are available in 21 wettable powder, 2 suspension concentrate, 2 oil dispersion, and 1 water dispersible granule forms.

Previous studies have shown that *B. subtilis* can promote plant growth and increase crop yield by solubilizing soil phosphorus, thus enhancing nitrogen fixation and producing indole acetic acid and siderophore (Hashem et al. 2019; Lastochkina et al. 2017; Ahmad et al. 2017). In addition, *B. subtilis* has strong antagonistic activities to many plant pathogens, such as *Rhizoctonia solani* (Tan et al. 2019), *Fusarium oxysporum f. sp. niveum* (Zhu et al. 2020), and *Colletotrichum fructicola* (Xu et al. 2020).

Hence, this study aimed to assess the potential of *B. subtilis JN005* (GenBank: KU302780) for rice blast control and rice growth improvement. This study used *B. subtilis JN005* to find out if it can effectively inhibit *M. oryzae* growth. The strain was isolated from a healthy rice plant among diseased rice hills of the susceptible cultivar Xiangzaoxian 24, a single-season cropping rice, in the mountainous areas of Taojiang, Hunan, China.

**Materials and Methods**

**Microorganisms, Media, Plant Materials, and Fungicides**

*B. subtilis JN005* and *M. oryzae* are stored in the Laboratory of Plant Pathogenic Microorganisms and Rice Diseases, Hunan Agricultural University, Changsha, China. Unless otherwise specified, *B. subtilis JN005* was grown on Nutrient Agar (NA) (Zhang et al. 2019). The phytopathogenic fungus *M. oryzae* was cultured and maintained on Potato Dextrose Agar (PDA) (He et al. 2019). The test rice variety was “Xiangwanxian No 12” from Hunan Hope Seed Industry Technology Co., Ltd., China. The fungicides used were *B. subtilis* WP from Deqiang Biological Co., Ltd., China, 40% isoprothiolane EC from Jiangsu Longdeng Chemical Co., Ltd., China, and 75% tricyclazole WP from Shanghai Hualian Biopharmaceutical Co., Ltd., China.

**Effect of *B. subtilis JN005* on Rice Seed Germination**

Rice seeds were soaked in a beaker containing water. Floating seeds were taken out and discarded, while the seeds that sunk were used in research. After removing the water, the seeds were sterilized by immersing in 70% alcohol for 30 s, then into 1% sodium hypochlorite for 1 min, and then rinsed off twice with sterile water (Anhar et al. 2019). Afterward, seeds were soaked in sterile water for 24 h, and then 100 seeds were evenly dispersed on petri dishes (*d* = 9 cm) with two sheets of filter papers moistened with 10 mL of *B. subtilis JN005* suspension at various concentrations: 1 × 10^8 cfu/mL, 1 × 10^7 cfu/mL, and 1 × 10^6 cfu/mL. Each petri dish was covered with a double wet gauze and then incubated for seven days at 28 °C in a dark culturing box. Controls were prepared by moistening the filter papers with 10 mL sterile water. Each treatment had three replicates and each petri dish was weighed every 12-h period, and the evaporated solution of each treatment was replenished to keep the solution concentration consistent during the treatment. Buds were cut, dried, and weighed on the seventh day. The germination energy (GE) was calculated on the fifth day based on the GB/T3543.4–1995 Rules for Agricultural Seed Testing—Germination Test in China. The germination rate (GR), germination index (GI), and vigor index (VI) were calculated on the seventh day:

\[
\text{GE} \ (\%) = \frac{\text{number of germinated seeds on the 5th day}}{\text{total number of seeds}} \times 100
\]

\[
\text{GR} \ (\%) = \frac{\text{number of germinated seeds on the 7th day}}{\text{total number of seeds}} \times 100
\]

\[
\text{GI} = \sum \left[ \frac{\text{days of germination}}{\text{corresponding number of germinated seeds}} \right]
\]
Effect of *B. subtilis* JN005 on Rice Seedlings

Surface sterilized rice seeds were sown into plastic pots containing field soil at 28 °C and 12-h light per day. Each pot (20 cm × 15 cm × 10 cm) was irrigated every seven days with 50 mL of *B. subtilis* JN005 suspension at various concentrations (1 × 10⁸ cfu/mL, 1 × 10⁷ cfu/mL, and 1 × 10⁶ cfu/mL) and 50 mL water for the control setup. Three pots were used for each treatment. Growth parameters of 35-day-old seedlings were measured, including plant height, root length, stem circumference, and fresh weight. Chlorophyll estimation was carried out following the method of Bisht et al. (2020). In brief, 0.10 g of fresh rice leaf tissue was harvested from each treatment, and was homogenized in 80% acetone, and centrifuged for 5 min. Then, the supernatant was obtained, and absorbance was measured through the UV–Vis spectrophotometer at 645 nm and 663 nm.

Effect of *B. subtilis* JN005 on Defense Enzymes Activity

Rice plants grown in plastic pots (20 cm × 15 cm × 10 cm) containing field soil at 28 °C and 12-h light per day were sprayed with various liquid treatments at 25 days. The experiment was designed with three replications and four treatments, viz, water (T1 = negative control), 2 × 10⁵ conidia/mL *M. oryzae* suspension (T2 = positive control), 1 × 10⁷ cfu/mL *B. subtilis* JN005 suspension (T3), and 1 × 10⁷ cfu/mL *B. subtilis* JN005 suspension + 2 × 10⁵ conidia/mL *M. oryzae* spore suspension (T4). Rice leaf samples were collected at 1, 3, 5, and 7 days after treatment. The activities of catalase (CAT), phenylalanine ammonialyase (PAL), peroxidase (POD), and superoxide dismutase (SOD) were examined using a relative kit (Nanjing Jiancheng Bioengineering Institute, China).

Effect of *B. subtilis* JN005 on Rice Blast Development on Detached Rice Leaves

Detached healthy rice leaves at the five-leaf stage were poked slightly with an inoculating needle and then placed into petri dishes with 0.1% 6-benzylaminopurine solution. For the preventive group, leaf surfaces were sprayed with *B. subtilis* JN005 suspension of 1 × 10⁷ cfu/mL first and were inoculated with *M. oryzae* spore suspension of 2 × 10⁵ conidia/mL after 24 h. For the curative group, leaf surfaces were sprayed with the bacterial suspension 24 h after being inoculated with the spore suspension. Other treatments used were sterile water (control), 40% isoprothiolane EC, and 75% tricyclazole WP in place of the JN005 strain suspension. All petri dishes were placed at conditions of 85%–100% relative humidity and temperature of 28 °C, with a 12-h photoperiod for seven days. Disease incidence was measured from 15 leaves for each treatment.

\[ \text{Disease incidence (\%)} = \left( \frac{\text{number of disease spots}}{\text{number of spots investigated}} \right) \times 100 \]

\[ \text{Disease index} = \sum \left( \frac{\text{number of infected plants in each category} \times \text{numerical values of each category}}{\text{total number of plants} \times \text{highest numerical values}} \right) \times 100 \]

\[ \text{Efficacy (\%)} = \frac{(\text{control disease index} - \text{treatment disease index})}{\text{control disease index}} \times 100 \]

Statistical Analyses

All analyses were carried out using the Dunnett’s T3 test \((P \leq 0.05)\) following one-way ANOVA of the IBM SPSS 22.0 software for Windows.

Results

Effect of *B. subtilis* JN005 on Rice Seed Germination

Significant growth promotion was observed in rice seeds treated with *B. subtilis* JN005 suspension (Fig. 1 and...
Compared to the control or sterile water treatment (Table 1), rice seeds treated with *B. subtilis* JN005 suspension at a population density of 1 × 10^7 cfu/mL showed the highest germination energy at (93.67 ± 0.67)%, germination rate at (94.00 ± 1.00)%, germination index at (167.11 ± 2.82), and vigor index at (37.81 ± 2.57). Values obtained were 16%, 14%, 15%, and 270% higher than values measured in germination energy, germination rate, germination index, and vigor index, respectively, from the control or sterile water treatment. Except on vigor index, the effects on rice seed germination from 1 × 10^6 cfu/mL bacterial cells treatments were not significantly different when compared with 1 × 10^8 cfu/mL, but both treatments showed significantly higher values than the control treatment.

### Effect of *B. subtilis* JN005 on Rice Seedlings

Growth parameters were measured with the application of *B. subtilis* JN005 suspension in potted rice seedlings, namely plant height, root length, stem circumference, and fresh weight (Table 2). Compared with water treatment, results show that *B. subtilis* JN005 suspension treatments exhibited growth-promoting effects on rice seedlings (Fig. 2). With the decrease of the concentration of *B. subtilis* JN005 suspension, the growth-promoting effect first increased and all

Data were mean ± SE (n = 3), different lowercase letters within a column indicated significant difference at 0.05 level

Fig. 2 Effect of *Bacillus subtilis* JN005 suspension at 1 × 10^7 cfu/mL treatment on rice seedlings (right) in comparison to the control or water treatment (left)
the indexes reached the maximum and then decreased when the concentration reached $1 \times 10^7$ cfu/mL. The \textit{B. subtilis} JN005 suspension of $1 \times 10^7$ cfu/mL increased root plant height (46%), root length (127%), stem circumference (54%), aboveground fresh weight (130%), and underground fresh weight (90%) as compared to the control after 35 days. The \textit{B. subtilis} JN005 inoculation induced changes in chlorophyll concentration. When rice seedlings leaves were inoculated with three concentrations of \textit{B. subtilis} JN005, the chlorophyll concentration became elevated compared to those uninoculated ones. Maximum significant improvement was observed in $1 \times 10^7$ cfu/mL bacterial cells inoculated leaves where Chl a, Chl b, and Total Chl increased by 161%, 155%, and 159%, respectively, compared to the sterile water or control treatment (Table 3).

**Effect of \textit{B. subtilis} JN005 on Defense Enzymes Activity**

In theory, \textit{B. subtilis} JN005 induces the CAT, PAL, POD, and SOD activities in rice leaves. Results show that activities of CAT, PAL, and SOD increased gradually, peaking at three days after application of \textit{B. subtilis} JN005 suspension of $1 \times 10^7$ cfu/mL (Fig. 3A, B, and C). Figure 3D shows that the activities of POD in the rice leaves increased dramatically after treatment with \textit{B. subtilis} JN005 suspension, and activity was highest at $1 \times 10^7$ cfu/mL bacterial cells on the fifth day. The POD activity showed longer duration, while other enzymes activities were opposite. The activities of CAT, PAL, SOD, and POD significantly increased in the plants treated with the combination suspensions of \textit{B. subtilis} JN005 and \textit{M. oryzae} spores (T4) compared to pathogen-inoculated positive control (T2). Rice leaves treated with the \textit{B. subtilis} JN005 suspension alone (T3) also showed significantly higher enzymatic activity compared to the water treatment (T1) and the pathogen-inoculated treatment (T2).

**Effect of \textit{B. subtilis} JN005 on Rice Blast Development on Detached Rice Leaves**

\textit{B. subtilis} JN005 suspensions were tested for its ability to control \textit{M. oryzae} through in vitro inoculation on rice leaves. Typical blast disease spots on rice leaves were observed (Fig. 4), and disease incidence was 100.00% in both the preventive and the curative groups inoculated with T2 $2 \times 10^5$ conidia/mL \textit{M. oryzae} suspension, T3 $1 \times 10^7$ cfu/mL \textit{B. subtilis} JN005 suspension, T4 $1 \times 10^7$ cfu/mL \textit{B. subtilis} JN005 suspension + $2 \times 10^5$ conidia/mL \textit{M. oryzae} spore suspension.
sterile water as control. In treatments with \(1 \times 10^7\) cfu/mL bacterial suspension, symptoms observed were significantly reduced, with disease incidence of only \((20.74 \pm 0.74)\%\) and \((24.44 \pm 1.28)\%\) in the preventive and in the curative groups, respectively. These results suggest that the JN005 strain displayed preventive effect and weak curative effect against the leaf blast. Additionally, the JN005 strain showed a comparable control effect of leaf blast with 40% isoprothiolane EC, but it was not as excellent as the 75% tricyclazole WP treatment (Table 4).

### Table 4 In vitro inoculation of Bacillus subtilis JN005 on detached rice leaves to showcase leaf blast incidence

| Treatment                        | Dilution ratio | The preventive group | The curative group |
|----------------------------------|----------------|----------------------|--------------------|
| Control (sterile water)          | 0              | 100.00 ± 0.00a       | 100.00 ± 0.00a     |
| 40% isoprothiolane EC           | 500            | 25.18 ± 0.74b        | 22.96 ± 0.74b      |
| 75% tricyclazole WP             | 1500           | 9.63 ± 1.48d         | 13.33 ± 1.28c      |
| \(1 \times 10^7\) cfu/mL B. subtilis JN005 | 0              | 20.74 ± 0.74c        | 24.44 ± 1.28b      |

Data were mean ± SE (n = 3), different lowercase letters within a column indicated significant difference at 0.05 level.

### Table 5 Biocontrol effects of Bacillus subtilis JN005 and WP on field-grown rice plants in two-year trial

| Treatments                  | Seeding | Maturity | Rice yield (g/m²) |
|-----------------------------|---------|----------|------------------|
|                            | Disease index | Efficacy (%) | Disease index | Efficacy (%) |                |
| Control                    | 3.66 ± 0.21a | –         | 5.28 ± 0.69a    | –             | 340.55 ± 12.55b|
| B. subtilis JN005, \(1 \times 10^7\) cfu/mL | 1.58 ± 0.13b | 58.82 ± 1.12 | 2.16 ± 0.13b | 58.39 ± 3.05 | 524.40 ± 17.88a |
| B. subtilis WP             | 1.32 ± 0.32b | 65.45 ± 7.18 | 1.64 ± 0.25b | 62.74 ± 7.13 | 488.15 ± 13.69a |

Data were mean ± SE (n = 6), different lowercase letters within a column indicated significant difference at 0.05 level.

**Effect of B. subtilis JN005 on Rice Blast in the Field**

The biocontrol efficacy of *B. subtilis* JN005 was conducted in field trials as well and the results are shown in Table 5. Compared with fungicide, *B. subtilis* WP and *B. subtilis* JN005 suspension \(\left(1 \times 10^7\right)\) cfu/mL showed similar levels of disease control. At seedling and maturity stages, rice treated with water (control) showed the most serious disease symptoms with disease indexes of \((3.66 \pm 0.21)\) and \((5.28 \pm 0.69)\), respectively. Meanwhile, rice treated with *B. subtilis* JN005 suspension \(\left(1 \times 10^7\right)\) cfu/mL had disease indexes of \((1.58 \pm 0.13)\) and \((2.16 \pm 0.13)\) at seedling and maturity stages, respectively, which were comparable to indexes of \((1.32 \pm 0.32)\) and \((1.64 \pm 0.25)\) measured in rice treated with *B. subtilis* WP. After spraying *B. subtilis* JN005 \(\left(1 \times 10^7\right)\) cfu/mL, rice blast was controlled up to \((56.82 \pm 1.12)\%\) and \((58.39 \pm 3.05)\%\) at seedling and maturity stages, respectively. The spray application of *B. subtilis* JN005 and fungicide *B. subtilis* WP in rice resulted in the plants’ overall vegetative growth improvement. Compared to the control, significant increases in rice yields were obtained from treatments of *B. subtilis* JN005 suspension \(\left(1 \times 10^7\right)\) cfu/mL at 54% and fungicide *B. subtilis* WP treatment at 43%. The values are mean of data trials conducted in 2 years.

**Discussion**

The fungus *M. oryzae* is one of the most destructive plant pathogens. It can cause outbreak of rice blast disease that could pose threats to global food security. *Bacillus* spp. has
a well-recognized potential against crop diseases and most of biocontrol agents have been developed from Bacillus spp. For example, B. subtilis GB03, known by its product name Companion, can antagonize Fusarium, Pythium, and Rhizoctonia (Dhakal and Singh 2019).

This research illustrated that the germination energy, germination rate, germination index, and vigor index of rice seeds treated with B. subtilis JN005 suspension (1 × 10^7 cfu/mL) have high values compared to measurements from sterile water or control treatment. Similarly, various growth parameters of rice seedlings were enhanced, such as plant height, root length, stem circumference, and fresh weight in rice seeds with all B. subtilis JN005 treatments compared to the control treatment. Leaves of rice seedlings inoculated with B. subtilis JN005 resulted in increased chlorophyll concentration than the water treatment. Therefore, results clearly indicate that germination and growth of rice seeds reinforce the role of Bacillus spp. as a plant growth promoter, as well as the findings of some previous studies (Naseer et al. 2020; Liu et al. 2020; Gholamalizadeh et al. 2017).

In fact, Bacillus spp. promote plant health and plant growth through nitrogen fixation, phosphate solubilization, and phytohormone production (Tiwari et al. 2019). Nitrogen-fixing microorganisms can absorb elemental nitrogen from the atmosphere and form compounds that serve as plant nutrients (Kuan et al. 2016). Phosphate solubilization microorganisms can help plant roots to accelerate the absorption of organic and inorganic phosphates from soil (Garcia and Delgado 2016). Bacillus spp. may directly raise plant yield via mechanisms that impart the production of phytohormones or plant growth regulators, such gibberellins, auxins, and ethylene (Park et al. 2017; Shahzad et al. 2017; Vicente et al. 2019). Additionally, this study revealed that rice yields of plants with B. subtilis JN005 treatments (524.40 ± 17.88) g/m² were higher than the water control (340.55 ± 12.55) g/m² and fungicide B. subtilis WP (488.15 ± 13.69) g/m² treatments. Similarly, rice yields in treatments B. siamensis 624.10 g/m² were found significantly higher than the untreated control 484.10 g/m² (Thampiban et al. 2018).

One effective biological control for multiple pathogens is the activation of the defense systems in the host plant (Jamali et al. 2020). This study showed that the accumulations of CAT, PAL, SOD, and POD in rice leaves were higher in the B. subtilis JN005 treatments compared to both the pathogen challenged and sterile water or control treatments. The results suggest that B. subtilis JN005 helped reduce the oxidative damage caused by the pathogen, M. oryzae through the upregulation of CAT, PAL, SOD, and POD activities. The JN005 strain triggered the plant’s defense mechanism that helped the plant to improve its resistance against pathogen infection. These findings are parallel with earlier reports implying the potential of biocontrol Bacillus spp. toward strengthening the defense enzymes activities that build up the defensive mechanism of rice plants against diseases (Rais et al. 2017; Elshakh et al. 2016).

Isoprothiolane and tricyclazole are extensively used fungicides on rice blast (Rijal and Devkota 2020; Elamawi et al. 2018). Inoculation experiment of detached rice leaves showed no significant difference between the JN005 strain 1 × 10^7 cfu/mL suspension and fungicide 40% isoprothiolane EC in controlling M. oryzae, but tricyclazole 75% WP was found to be most effective among three treatments. Additionally, B. subtilis JN005 had better preventive effect than its curative effect for leaf blast control. The results of a 2-year field experiment studies revealed lower blast disease indexes in the B. subtilis JN005-treated group at (1.58 ± 0.13) and (2.16 ± 0.13) during seedling and maturity stages of rice plants, respectively, compared with (1.32 ± 0.32) and (1.64 ± 0.25) derived from the B. subtilis WP-treated group. B. subtilis JN005 and B. subtilis WP have almost similar effects to blast disease; thus, the JN005 strain exhibits great promise in suppressing disease severity following M. oryzae infection. Consequently, the JN005 strain may be potentially used for the biocontrol of rice blast and its antagonistic activity indicates a prospect for practical applications in agriculture sustainable development.

Reportedly, Bacillus spp. excrete extracellular metabolites, such as antibiotics, cell wall hydrolases, and siderophores that have antagonistic activity on plant pathogens (Miljaković et al. 2020; Kaspar et al. 2019). For example, B. amyloliquefaciens strains VB7 reduced stem rot incidence in greenhouse-grown carnations and that antimicrobial compounds detected include fatty acids and phenols (Vinodkumar et al. 2017). Hence, a future study on B. subtilis JN005 will be conducted to determine which antibiotics it produces that curtail the incidence of plant diseases.
