(Received 2 May 2018; revised manuscript received 16 May 2018; published online 25 June 2018)

The Lieb–Liniger model is a prototypical integrable model and has been turned into the benchmark physics in theoretical and numerical investigations of low-dimensional quantum systems. In this note, we present various methods for calculating local and nonlocal \( M \)-particle correlation functions, momentum distribution, and static structure factor. In particular, using the Bethe ansatz wave function of the strong coupling Lieb–Liniger model, we analytically calculate the two-point correlation function, the large moment tail of the momentum distribution, and the static structure factor of the model in terms of the fractional statistical parameter \( \alpha = 1 - 2/\gamma \), where \( \gamma \) is the dimensionless interaction strength. We also discuss the Tan’s adiabatic relation and other universal relations for the strongly repulsive Lieb–Liniger model in terms of the fractional statistical parameter.

Keywords: correlation function, momentum distributions, structure factor, contact

1. Introduction

The Bethe ansatz, which was introduced in 1931 by Hans Bethe, has become a powerful method to obtain exact solutions of one-dimensional (1D) quantum many-body systems. In 1963, Lieb and Liniger\textsuperscript{[1]} solved the 1D many-particle problem of \( \delta \)-function interacting bosons by the Bethe’s hypothesis. The ground state, the momentum, and the elementary excitations were obtained for this model by using the Lieb–Liniger solution. In this context, a significant step was made on the discovery of the grand canonical description of this Lieb–Liniger model by Yang and Yang in 1969.\textsuperscript{[2]} Now, this grand canonical approach is called Yang–Yang thermodynamic method. The Yang–Yang thermodynamics of the Lieb–Liniger Bose gas provides benchmark understanding of quantum statistics, thermodynamics, and quantum critical phenomena in many-body physics, see a review.\textsuperscript{[3,4]} In the context of ultracold atoms, the 1D Bose gas with a repulsive short-range interaction characterized by a tunable coupling constant exhibits rich many-body properties. This model thus becomes an ideal test ground to explore fundamental many-body phenomena ranging from equilibrium to nonequilibrium physics in the experiment.\textsuperscript{[5–10]}

Despite Lieb–Liniger is arguably the simplest integrable model, the calculation of the correlation functions is extremely challenging due to the complexity of the Bethe ansatz many-body wave function of the model. The study of correlation functions has long been being an important theme in the physics of ultracold quantum gases since they provide information of quantum many-particle interference and coherence beyond the solely spectra of the systems. Therefore, there has been much theoretical and experimental interest in the local, non-local, and dynamical correlation functions at zero and finite temperatures via numerous methods based on exactly solvable models, see Refs. [11]–[22].

For sufficiently strong interaction and sufficiently low density, the 1D Lieb–Liniger gas enters the Tonks–Girardeau (TG) regime, in which bosons behave like impenetrable particles (hard-core bosons). Such impenetrable bosons behave mostly like the free fermions that build up the Girardeau’s Bose–Fermi mapping.\textsuperscript{[23]} In fact, the 1D Lieb–Liniger Bose gas with the interacting strength \( c_B \) can map onto the fully-polarized fermions with a p-wave interaction of strength \( c_F = 1/c_B. \textsuperscript{[24]}\) As a result of the Bose–Fermi mapping, the energy spectra of the Bose and corresponding Fermi systems are identical at the TG regime. The observables that can be given in terms of the local density are identical for both systems, such as dynamical density–density correlation function, see Ref. [25]. However, this mapping for the off-diagonal correlation function does not like to be true, for example, the momentum distribution. The Bose–Fermi mapping has tremen-

ous applications in the study of strongly interacting quantum gases of ultracold atoms. An expansion of the reduced density matrices for 1D bosons has been first derived by Lenard[26,27] using Bose–Fermi mapping at Tonks Girardeau regime. After that, there were superb findings in the literature.[28–35]

In the context of correlation functions, the Fourier coefficients have an important physical significance. By taking Fourier transform of the one- and two-particle correlation functions, the momentum distribution and the static structure factor of the system can be obtained, respectively. The first few terms of the short-range series expansion of the one-particle correlation function $g_1(x) = 1 + \sum_{n=0}^{\infty} c_n/|x|^n$ have been calculated in Refs. [28], [36], and [37], where $c_1 = 0$, $c_2 = 1/2(e(\gamma) - \gamma e(\gamma))$, $c_3 = \gamma^2 e(\gamma)/12$, etc. A further study on the connection between the non-local one-body and local three-body correlation functions was presented in Ref. [38].

The systems described by the Hamiltonian with short distance interaction (δ-function type) show singular behavior of the wave function when two or more colliding particles coincide. Consequently, the large momentum tail of the momentum distribution has a universal power-law decay, i.e., $w(p) \sim C/p^\alpha$, where $C$ is an extensive quantity called Tan’s contact.[39–41] For the power law tail of the momentum distribution, the contact characterizes many universal properties of the systems that are independent of the details of the contact interaction and the dimensionality,[42] such as the energy adiabatic relation, the universal connection to the structure factor, and the pressure relation. The contact measuring the correlation of such systems of this kind in short distance limit is proportional to the probability of finding two atoms at zero separation,[39–41] see more studies on the contact in Refs. [43]–[45]. The contact can be computed from the free energy of the system via the Helman–Feynmann theorem,[46] or from the prefactor of the high-frequency power-law decay of the single particle correlator,[47] or by the product expansion field theory method.[48] Very recently, p-wave contacts were found to exhibit universal relations in the ultracold atomic systems with a p-wave interaction.[49] In this scenario, the momentum distribution, s-wave and p-wave contact relations have been attracted a great deal of attention from theory and experiment.[36,37,42,46,52–56]

On the other hand, the static structure factor contains information about the static correlation properties of a system and directly relates to the pair distribution function or the normalized density–density correlator or spin–spin correlator.[25] In the low-momentum regime and the infinite repulsive regime, hydrodynamic theory predicts that the static structure factor should behave linearly with momentum $k$.[42] The static structure factor at small momentum $k$ is related to the sound velocity ($v_s$) by $S(k) = h|k|/(2\pi v_s)$. For high momentum, the structure factor always converges to 1.[42]

The Fourier transform of the time-dependent density–density correlation function is known as the dynamical structure factor,[21,58,59] and expresses the probability of excitation by an infinitesimal perturbation.

The duality between interacting spinless bosons and fermions in 1D[24,32] can be adopted to the framework of the generalized fractional statistics, which interpolate continuously between bosons and fermions. In fact, while three dimensions particles can be only bosons or fermions, in lower dimensionality it has been recognized that particles with fractional statistics intermediate between bosons and fermions[60–66] due to the transmission between dynamical interaction and statistical interaction. The 1D strongly repulsive Bose gas at low temperatures is equivalent to a gas of ideal particles obeying the non-mutual generalized exclusion statistics (GES) with a statistical parameter $\alpha = 1 - 2/\gamma$, where $\gamma$ is the dimensionless interaction strength.[66] Using such a mapping, the quasimomenta of $N$ strongly interacting bosons map to the momenta of $N$ free fermions via $k_i \approx \alpha k_i^\dagger$ with $i = 1, \ldots, N$.[66] By using the fractional statistical parameter $\alpha$, the $M$-body local correlation functions and non-local correlation functions in terms of the wave function of $M$ bosons at zero collision energy and zero total momentum have been computed analytically up to next-to-leading order.[19] In this paper, we analytically calculate various correlation functions in terms of the statistical parameter $\alpha$. In particular, we calculate the two-point correlation function, the power-law tail of the momentum distribution, and discuss the structure factor of the 1D Lie–Liniger model of ultracold atoms with finite strong interaction strength. For Tonks gas, i.e., $\alpha = 1$, our results are equivalent to those of the Tonks–Girardeau gas.

The paper is organized as follows. In Sections 1 and 2, we briefly introduce the Lieb–Liniger model and recall some results of higher-order local correlations for the 1D interacting bosons. In Section 3, we present the derivation of the non-local $2M$-point correlation function. In Section 4, we prove the power-law decay of the momentum distribution of the 1D interacting bosons at large momenta. The large momentum tail of the momentum distribution determines Tan’s contact in term of the fractional statistical parameter $\alpha$. In this section, we also discuss the static structure factor. The last section presents our conclusion.

2. Model of interest

A model of 1D spinless $N$ bosons with δ-function interaction is described by the Hamiltonian

$$H_N = \frac{\hbar^2}{2m} \left( \sum_{j=1}^{N} -\partial_j^2 + 2e \sum_{1 \leq j < i \leq N} \delta(x_j - x_i) \right),$$

where $m$ is the mass of bosons and $e = -2/\alpha_{1D}$ is a coupling constant. Here, $\alpha_{1D}$ is the 1D scattering length and $\hbar$ is the

070306-2
Plank constant. The positive and negative $c$ values correspond to the repulsive and attractive interactions, respectively, and $c = 0$ for free particles.

With the periodic boundary condition $\psi(0, x_2, \ldots, x_N) = \psi(x_2, \ldots, x_N, L)$, in the domain $0 \leq x_1 \leq x_2 \leq \cdots \leq x_N \leq L$, the Betha ansatz wave function can be written as:

$$\psi(x_1, \ldots, x_N) = \sum_{P} (-1)^P \left[ \prod_{1 \leq i, j \leq N} \left( \frac{ic + k_P - k_{P'}}{ic - k_P + k_{P'}} \right)^{1/2} \right] \psi_i \sum_{i=1}^{N} k_{P} x_j,$$

where $(-1)^P$ is parity for the permutations and the sum runs over $N!$ permutations $P$ with respect to quasi-momenta $\{k_1, k_2, \ldots, k_N\}$. After expanding the amplitude of the wave function, we have

$$\psi(x_1, \ldots, x_N) = A(c) \sum_{P} (-1)^P e^{\frac{N}{2} k_P x_j}, \quad \text{for strong coupling},$$

$$N! - \frac{k}{2} Y(x_1, \ldots, x_N), \quad \text{for weak coupling},$$

where $A(c) = (1 + \frac{1}{c} \sum_{j=1}^{N} (2j - N - 1) \partial_j)$ and

$$Y(x_1, \ldots, x_N) = \sum_{P} \left( \sqrt{\frac{2}{L}} \sum_{i<j} F(q_i - q_j) + \sqrt{\frac{2}{L}} \sum_{j=1}^{N} q_j x_j \right)^2,$$

here $F(q_i - q_j) = (q_i - q_j)^{-1}$ and $q_j = k_j \sqrt{L/2c}$. The derivation of the wave function for weak coupling can be seen in Appendix A, also see the case of the 1D p-wave fermions in Ref. [56]. Moreover, the normalization factor of the wave function is defined by $N^2 = \int_{0}^{L} \cdots \int_{0}^{L} |\psi(x_1, x_2, \ldots, x_N)|^2$. Further, the wave function is continuous whenever two particles are close to each other, and the discontinuity in the derivative of the wave function is $2c$ when two particles overlap. These are known as boundary conditions of the wave function with $\delta$ potential. [11]

For a given set of quasi-momenta $\{k_j\}$, the total momentum and the energy of the system are $\mathcal{P} = \sum_{j=1}^{N} k_j$ and $E = \sum_{j=1}^{N} k_j^2$, respectively.

For a finite large interaction strength, the quasimomenta of the bosons $k_1, k_2, \ldots, k_N$ deviate from pure Fermi statistics, they obey the non-mutual general exclusive statistics (GES). [60,61,66] The deviation from Fermi statistics is determined by the non-mutual GES parameter $\alpha = 1 - 2/\gamma$. [66] If the total momentum $k_1 + \cdots + k_N = 0$, we have the following relation:

$$k_j = k_j^F \alpha + O(c^{-2}),$$

where $k_j^F = 2\pi \mathcal{I}_j/L$ and the $\mathcal{I}_j$’s are integers satisfying $\mathcal{I}_1 < \cdots < \mathcal{I}_N$. In fact, the equal spacing in momenta reveals a nature of non-mutual fractional statistics. Here, the wave function of 1D interacting bosons can be given in terms of the GES $k_j = k_j^F \alpha$.

functions which were recently derived by using the GES relation Eq. (4). It turns out that the GES is convenient to calculate the local $M$-body correlation functions.

3. Local $M$-body correlation functions

We first would like to recall some results of local $M$-body correlation functions which have been studied in Refs. [11]–[22]. In particular, we discuss the results of the correlation

$$g_M = \frac{N!}{(N - M)!} \frac{\int_{0}^{L} \cdots \int_{0}^{L} dx_{M + 1} \cdots dx_N |\psi(x_1, x_2, \ldots, x_N)|^2}{\int_{0}^{L} \cdots \int_{0}^{L} dx_1 \cdots dx_N |\psi(x_1, x_2, \ldots, x_N)|^2}.$$

In the strong coupling limit, one can expand the BA wave function Eq. (3) in terms of the power of $1/c$, from which the numerator and denominator can be calculated analytically. [19]

$$g_M = \frac{N! c^{-M(M-1)/2} \int_{0}^{L} \cdots \int_{0}^{L} \Delta(x_{M+1} \cdots x_N)_{x_{M+1} = \cdots = x_{M+1} = 0}^2 dx_{M+1} \cdots dx_N + O(c^{-M(M-1)/2})}{(N - M)! \left[ 1 + \frac{2(N-1)}{c} + O(c^{-2}) \right] \int_{0}^{L} \cdots \int_{0}^{L} \Delta(x_1, x_2, \ldots, x_N)^2 dx_1 \cdots dx_N}.$$
Here, $\Delta_M(\partial_x) = \prod_{1 \leq i < j \leq M} \left( \frac{d}{dx_j} - \frac{d}{dx_i} \right)$ is the Vandermonde determinant and $\phi(x_1, \ldots, x_N) = \sum_p (-1)^p e^{i \Sigma_{j=1}^{N} k_j x_j}$ for all $x$’s. In this case, using the GES Eq. (4), $k_i = k_i^0 \alpha$, and making a scaling change $x_i = x_i^F/\alpha$ for $i = 1, \ldots, N$, thus we can rewrite Eq. (7) as

$$g_M = \frac{\prod_{M-1}^{M \cdot \mu}}{(N-M)!} \left[ \frac{\prod_{M-1}^{M \cdot \mu}}{\alpha^{-N-M} \prod_{M-1}^{M \cdot \mu}} \right] \left[ \sum_{\Delta_M(\partial_x) \phi(x_1^F, \ldots, x_N^F)} \sum_{x_1^F, \ldots, x_N^F} \frac{1}{2} \frac{d}{dx_{1^F}^F} \cdots \frac{d}{dx_{N^F}^F} \right]_{x_1^F = \cdots = x_M^F = 0}$$

(8)

to the order $O(c^{-M(M-1)^2})$. Here, $\phi(x_1^F, \ldots, x_M^F) = \sum_p (-1)^p e^{i \Sigma_{j=1}^{M} k_j^F x_j^F}$. Since $\phi(x_1, \ldots, x_N)$ is a Slater determinant, by applying Wick’s theorem and changing variable $k^F = 2\pi n_c$, then the $M$-body correlation function reads

$$g_M = M! n^M (2\pi/\gamma)^{M(M-1)/2} \alpha^M 1 \prod_{j=0}^{M-1} h_j,$$

(9)

where the dimensionless parameter $\gamma = c/n$, the liner density is given by $n = N/L$ and $N(z) = (1 + \exp(\frac{\gamma}{2}(2\pi nc)^2 - \mu))^{-1}$, $T$ and $\mu$ are the temperature and the chemical potential of the 1D Bose gas, respectively. Calculating the multiple integrals in Eq. (9) by using the orthogonal polynomials in the random matrix theory, we can give the $M$-particle local correlation function as

$$g_M = (M!)^2 n^M (2\pi/\gamma)^{M(M-1)/2} \alpha^M 1 \prod_{j=0}^{M-1} h_j,$$

(10)

where $h_j$’s are the norms-squares of the monic orthogonal polynomials satisfying $\int_{-\infty}^{\infty} P_j(z) \overline{P_j(z)} N(z) dz = h_j \delta_j$. Considering the distribution of particles at the ground state and applying the Sommerfeld expansion, we have general formulas for the higher-order local correlation function in two temperature regimes

$$g_M = \begin{cases} \left( \frac{\prod_{j=1}^{M/M-1} \alpha^{M-1} (\pi/\gamma)^{M(M-1)}}{\prod_{j=1}^{M/M-1} (2j-1)!!} \right)^2 \left( 1 + \frac{1}{4} M^2 (M^2 - 1) \left( \frac{T}{\pi T_d} \right)^2 \right) + O \left( \frac{T}{\pi T_d} \right)^2, & T \ll T_d, \\ (M!)^2 \alpha^{M-1} \left( \frac{T}{2\gamma^2 T_d} \right)^{M(M-1)/2} \prod_{j=0}^{M-1} j!, & T_d \ll T \ll \gamma^2 T_d, \end{cases}$$

(11)

where $T_d \equiv \hbar^2 n^2 / (2mk_B)$ is the quantum degeneracy temperature. In the above calculation, the statistical parameter $\alpha$ in the quasi-momenta of the hardcore bosons can be extracted as a factor giving the next-order corrections in the correlation function (11). In such a way, the integrant in the correlation function (8) reduces to the Vandermonde determinant with respect to the wave function of the free fermions. Then the Wick’s theorem and random matrix theory are used to obtain the explicit form of $M$-body correlation function (11). However, it would be extremely difficult to obtain higher-order correction terms beyond the form of Eq. (11).

3.2. Weak coupling regime

For the weak coupling case, one can easily use the wave function (3) to calculate the $M$-body correlation function

$$g_M^w(y_1, \ldots, y_M; x_1, \ldots, x_M) = \frac{N!}{(N-M)! N^2} \int_0^L \cdots \int_0^L dx_{M+1} \cdots dx_N \left( N! - \frac{\gamma}{2} Y(y_1, \ldots, y_M, x_M+1, \ldots, x_N) \right)^\frac{N! - \gamma}{2} Y(x_1, \ldots, x_N)$$

$$= \frac{N!}{(N-M)! N^2} \left[ N!^2 L^{N-M} - N! \left( \frac{\gamma}{2} \right)^L \sum_{x_{M+1} \cdots x_N} [Y(y_1, \ldots, y_M, x_M+1, \ldots, x_N)]^x Y(x_1, \ldots, x_N) \right] + O(c^2).$$

(12)

So, the $M$-particle local-correlation function becomes

$$g_M^w(0, \ldots, 0; 0, \ldots, 0) = \frac{N!}{(N-M)! N^2} \left[ N!^2 L^{N-M} - N! \left( \frac{\gamma}{2} \right)^L \sum_{x_{M+1} \cdots x_N} [Y(0, \ldots, 0, x_M+1, \ldots, x_N)]^x \right] + O(c^2),$$

(13)

where $Y(0, \ldots, 0, x_M+1, \ldots, x_N) = \sum_p \left( \frac{T}{\pi} \sum_{k < j} F(q_p - q_j) \right) + \sqrt{\frac{T}{\pi} \sum_{j=M+1}^N q_p x_j}$. 

070306-4
In fact, the Bogoliubov method is very convenient and useful for the study of the weak coupling Bose gas in any dimension. In this Bogoliubov approach, one considers a large fraction of particles in the lowest quantum state and excites a small fraction of particles out of the Bose-condensed particles with weakly repulsive interacting Bose gas. Therefore, in this regime, the field operator $\hat{\Psi}$ can be considered as a sum of the condensate part $\psi_0$ and a non-condensate part $\psi'$, such as $\hat{\Psi} = \psi_0 + \psi'$. The density of the system is $n = n_0 + n'$, where $n_0 = \langle \psi_0 \psi_0^\dagger \rangle$ and $n' = \langle \psi'^\dagger \psi' \rangle$ represent the condensed particle density and non-condensed particle density, respectively. For a uniform condensate, the ground state solution is $\psi_0 = \sqrt{n_0} \exp(i\mu t/\hbar)$, where the chemical potential is given by the relation $\mu = n_0 \omega$, see a detailed study given in Ref. [13].

In the weak coupling regime, $\gamma \ll 1$, the mean field interaction energy per particle is proportional to $n g$, where $g = \hbar c^2/m$. It is proper to define the correlation length $l_c = \hbar / \sqrt{m g}$. At temperature $T < T_d$, over a wide range of parameters $l_c < l_\phi$, we can have the condition $T / T_d \ll \sqrt{T}$. [13] Here, $l_\phi$ is the phase coherence length and $T_d = \hbar^2 n^2 / 2m$ is the quantum degeneracy temperature. In this case, the condensate fraction contains the contribution of excitations with momenta $k \ll k_0 \ll k_c^{-1}$ and non-condensate parts provided excitations with $k \sim k_c$. [13,15] In order to complete our discussion on the local $M$-body correlation, the necessary calculation of the correlation function is shown in Appendix B. What below is a summary of the correlation functions based on the Bogoliubov approach.

The $M$-particle correlation function for 1D bosons at weak coupling regime is given by

$$g_M^w = \langle (\psi_0' + \psi')^M (\psi_0 + \psi')^M \rangle = n^M \left( 1 + \frac{M(M-1)}{n} \langle \langle \psi'^\dagger \psi' \rangle \langle \psi' \psi' \rangle \rangle \right),$$

dealing with the $M$th order density $n^M = n^M - Mn^{M-1} \langle \langle \psi'^\dagger \psi' \rangle \rangle + O(\langle \langle \psi'^\dagger \psi' \rangle \rangle^2)$. Equation (B5) shows that $g_M^w$ depends on the normal density $\langle \langle \psi'^\dagger \psi' \rangle \rangle$ and anomalous density $\langle \langle \psi' \psi' \rangle \rangle$ of the non-condensed part. Considering the form of the non-condensate part, $\psi' = \sum_k (u_k b_k e^{-i\epsilon_k t/\hbar} - v_k b_k^\dagger e^{i\epsilon_k t/\hbar})$, $g_M^w$ can be converted into

$$g_M^w = n^M \left( 1 + \frac{M(M-1)}{2\pi n} \int_{-\infty}^\infty \frac{dk}{\epsilon_k} \left( \frac{E_k}{\epsilon_k} (N_k + 1) - 1 \right) \right)$$

by Bogoliubov transformation, where $b_k, b_k^\dagger$ are operators of excitations which obey the usual commutation relations, $\epsilon_k$ are their eigen energies, and $u_k, v_k$ are their eigenfunctions. This result illustrates that $g_M^w$ depends on the occupation number of the excitation $N_k$, excitation energy $\epsilon_k$, and system energy $E_k$. In fact, $g_M^w$ varies with the temperature range since $N_k = 0$, $\epsilon_k \approx \sqrt{E_k^2 + 2m \epsilon_k}$ at zero temperature and $N_k \neq 0$, $\epsilon_k = \hbar k v_s$ at non-zero temperature. Here, $v_s \approx \sqrt{n_0 g/m}$ is the sound velocity and the distribution $N_k$ takes the form $(e^{\epsilon_k/T} - 1)^{-1}$ for the temperature $T \ll \mu$ and $T \gg \mu$, respectively. However, $E_k = \hbar k^2 / 2m$ and $\mu \approx n_0 g$ at low temperature.

This study follows the method developed by Gangardt and Shlyapnikov in Ref. [13]. The elementary excitation of the Bose-condensed system involves vacuum fluctuations and thermal fluctuations. At zero temperature, thermal fluctuations are suppressed and vacuum fluctuations dominate. This scenario becomes reversed at $\mu \ll T \ll \sqrt{T} T_d$. However, both vacuum and thermal fluctuations create excitations at $T \ll \mu$.

According to these configurations, and after a length algebra, the $M$-particle correlation, Eq. (15), is given by

$$g_M^w = n^M \left( 1 + \frac{M(M-1)}{2\pi n} \int_{-\infty}^\infty \frac{dk}{\epsilon_k} \left( \frac{E_k}{\epsilon_k} (N_k + 1) - 1 \right) \right)$$

These results are not valid for $T \geq T_d \sqrt{T}$, belonging to quantum decoherence regime. The detailed calculation is presented in Appendix B. This result has been reported in Ref. [13]. The study of 2-body correlations was also reported in Ref. [14], while the 2-body, 3-body correlation functions at zero temperature were studied in Ref. [15].

## 4. Non-local correlation functions

The $M$-particle non-local correlation is a measure of the probability of observing $M$ particles at different points and defined by

$$g_M (x_1, \ldots, x_M; x'_1, \ldots, x'_M) = \frac{N!}{(N-M)!} \int_{0}^{L} \ldots \int_{0}^{L} dx_{M-1} \ldots dx_N |\psi(x_1, \ldots, x_M, x_{M+1}, \ldots, x_N)\rangle \int_{0}^{L} \ldots \int_{0}^{L} dx_1 \ldots dx_N |\psi(\ldots)\rangle^2$$

070306-5
The Galilean invariance is used in the above equation. The short distance non-local correlation function \( \langle \Psi^\dagger(x') \cdots \Psi^\dagger(x'_N) \Psi(x_M) \cdots \Psi(x_1) \rangle \) of the strongly repulsive Bose gas was studied in terms of the wave function of \( M \) bosons at zero collision energy and zero total momentum in Ref. [19].

4.1. Strong coupling regime

We first consider the non-local correlation function of strongly interacting 1D bosons with \( c = \infty \). Let us shorten our notation \( g_M(x_1, \ldots, x_M) = g_M(x_1, \ldots, x_M; 0, \ldots, 0) \). According to the Girardeau’s Bose–Fermi mapping [23] we have \( g^B_M(x_1, \ldots, x_M) \approx |g^F_M(x_1, \ldots, x_M)| \) in the limit \( c \to \infty \). Thus the \( M \)-particle correlation is rewritten as

\[
g_M(x_1, \ldots, x_M) = \frac{N!}{(N-M)!} \iint_0^L \cdots \int_0^L \cd x_M \cdots \cd x_1 |\Psi^F_N|^2, \tag{18}
\]

where \( N \)-particle fermion wave function \( \Psi^F_N \) has a determinant form and the norm of the wave function can be expressed as

\[
|\Psi^F_N|^2 = \det \left( \frac{\sin(N\pi(x^2_j - x^2_i)/L)}{\sin(\pi(x^2_j - x^2_i)/L)} \right)_{i,j=1,\ldots,N},
\]

and the normalization factor \( \iint_0^L \cd x_M \cd x_1 |\Psi^F_N|^2 = N!L^N \). By changing the variable as \( t_j = 2\pi x_j^F/L \), equation (18) becomes

\[
g_M(t_1, \ldots, t_M) = \frac{(2\pi)^M}{(N-M)!LM} \iint_0^L \cd t_{M+1} \cd t_N \left| \det \left( \frac{\sin(N(t_j - t_i)/2)}{2\pi \sin((t_j - t_i)/2)} \right) \right|_{j,j=1,\ldots,N}. \tag{19}
\]

Theorem 1 [67] Let \( K(x,y) \) be a function with real, complex, or quaternion values, such that \( K^* = K(y,x) \), where \( K^* = K \) if \( K \) is real, \( K^* \) is the complex conjugate of \( K \) if it is complex, and \( K^* \) is dual of \( K \) if it is a quaternion. Assume that

\[
\int K(x,y)K(y,z)\,dy = K(x,z) + \lambda K(x,z) - K(x,z)K, \tag{20}
\]

or symbolically

\[
K \ast K = K + \lambda K - K, \tag{21}
\]

with \( \lambda \) a constant quaternion. Let \( [K(x_i,x_j)]_N \) denote the \( N \times N \) matrix with its \((i,j)\) element equal to \( K(x_i,x_j) \). Then

\[
\int \det[K(x_i,x_j)]_N \, dx_N = (A - N + 1) \det[K(x_i,x_j)]_{N-1}, \tag{22}
\]

where \( A = \int K(x,y)\,dx \). When \( K(x,y) \) is real or complex, the variable \( \lambda \) vanishes.

We further observe that the elements of the determinant in Eq. (19) satisfy

\[
\int_0^{2\pi} \frac{\sin(N(t_j - t_i)/2)}{2\pi \sin((t_j - t_i)/2)} \, dt_j = N, \tag{23}
\]

\[
\int_0^{2\pi} \frac{\sin(N(t_j - t_i)/2)}{2\pi \sin((t_j - t_i)/2)} \, dt_i = \frac{\sin(N(t_j - t_i)/2)}{2\pi \sin((t_j - t_i)/2)}, \tag{24}
\]

and \( A = N \) is a constant. Therefore, according to the theorem, the \( M \)-partical non-local correlation function can be written as

\[
g_M(t_1, \ldots, t_M) = \frac{(2\pi)^M}{LM} \left| \det \left( \frac{\sin(N(t_j - t_i)/2)}{2\pi \sin((t_j - t_i)/2)} \right) \right|_{j,j=1,\ldots,M}, \tag{25}
\]

which can be used for calculating different nonlocal correlation functions of Tonks–Girardeau Bose gas.

4.2. Subleading contribution in 2-body correlation

Forrester et al. [30] have derived the \( O(1/c) \) order correction to the two-body non-local correlation function by expanding the momentum of bosons in the 1D Lieb–Liniger model with a finite strong repulsion. This subleading contribution can also be retrieved by using the fractional statistics following their analytical process. When we consider the non-local correlations, the positions of the particles (i.e., the permutation orders in the wave function) are very important. In the local correlation function, we have used the GES, \( k_l = ak_l^F \), the coordinates of the particles are demanded by a rescaling \( x_i \sim x_l^F/\alpha \). In contrast, such a rescaling of the particles’ coordinates in a calculation of the non-local correlation function works only for the strong repulsion limit, i.e., \( x_i/c \ll 1 \). For calculating the non-local correlation function, we will use Forrester et al. [30] expansion method in term of the statistical parameter \( \alpha \).

For our convenience, we fix the number of total particles \( N + 2 \) in the domain \( 0 \leq y \leq x_1 \leq \cdots \leq x_j \leq \cdots \leq x_N \leq L \) and label the particle positions as \( (y,x_1,\ldots,x_j,y,x_{j+1},\ldots,x_N) = (\tilde{x}_1,\tilde{x}_2,\ldots,\tilde{x}_{N+2}) \). Then the two-body non-local correlation function reads

\[
g_N^{N+2}(y,x) = \frac{(N+2)!}{N!} \times \int_0^L \cd y_1 \cd x_1 \cd y_2 \cd x_2 |\Psi_{N+2}|^2, \tag{26}
\]
For our convenience in notation, we can denote the wave function in Eq. (5) as

\[ \Psi^{N+2} \equiv \Psi(x, x_1, \ldots, x_j, x_{j+1}, \ldots, x_N) = \Psi(\hat{x}_1^F, \ldots, \hat{x}_{N+2}^F) \]

\[ = \left( 1 + (\alpha - 1) \sum_{l=1}^{N+2} \frac{\partial}{\partial x_l} \right) \Psi_{N+2}^F \]

\[ + \frac{N+2}{c} \sum_{l=1}^{N+2} (2l - (N + 2) - 1) \frac{\partial}{\partial x_l} \psi_{N+2}^F. \]  

Thus, the operators in the wave function can be expanded as

\[ \sum_{l=1}^{N} \frac{\partial}{\partial \hat{x}_l^F} = \frac{\partial}{\partial y} + \frac{\partial}{\partial x} \sum_{l=1}^{N} \frac{\partial}{\partial x_l}. \]  

\[ \sum_{l=1}^{N+2} (2l - (N + 2) - 1) \frac{\partial}{\partial x_l} = -(N+1) \frac{\partial}{\partial y} + \sum_{l=1}^{N} (2l - (N + 1) - 1) \frac{\partial}{\partial x_l} \]

\[ + (2(j + 1) - N - 1) \frac{\partial}{\partial x_j} + \sum_{l=j+1}^{N} (2(l + 1) - N - 1) \frac{\partial}{\partial x_l}. \]  

Let \( y = 0 \), and \( \Psi_{N+2}^F \) depends only on \( x_1, \ldots, x_N \) variables. At the ground state, the system has zero total momentum, i.e., \( \frac{\partial}{\partial y} = -(\frac{\partial}{\partial x} + \sum_{l=1}^{N} \frac{\partial}{\partial x_l}). \) The wave function of free fermions vanishes when two particles coincide, i.e., \( \Psi_{N+2}^F = 0 \) at \( x_l = 0, L, x_j (j \neq l). \) Therefore,

\[ \int_{\hat{x}_1 \leq \cdots \leq \hat{x}_j \leq \cdots \leq \hat{x}_{N+2}} dx_l \frac{\partial}{\partial x_l} |\Psi_{N+2}^F|^2 = 0, \]

\[ \int_{\hat{x}_1 \leq \cdots \leq \hat{x}_j \leq \cdots \leq \hat{x}_{N+2}} dx_l x_j \frac{\partial}{\partial x_l} |\Psi_{N+2}^F|^2 \]

\[ = -\int_{\hat{x}_1 \leq \cdots \leq \hat{x}_j \leq \cdots \leq \hat{x}_{N+2}} |\Psi_{N+2}^F|^2 dx_l. \]  

Taking together these conditions with Eq. (29), we may show that \( N^2 = \alpha^{-N+1} (N+1)!L^{N+1} \) and

\[ g_2^{N+2}(0, x) \]

\[ = \alpha^{N+1}\left[ 1 + (\alpha - 1)\left( x \frac{\partial}{\partial x} - N \right) \right] g_2^{N+2,F}(0, x) \]

\[ + \frac{1}{N^2} \sum_{a \neq j} \int \cdots \int_{\hat{x}_1 \leq \cdots \leq \hat{x}_{N+2}} dx_1, \ldots, dx_N (j + 1) \]

\[ \times \frac{\partial}{\partial x_j} \Psi_{N+2}^F(0, x), \]  

where \( \Psi_{N+2}^F(0, x_1, \ldots, x_N) \equiv \Psi_{N+2}^F(0, x). \)

Furthermore, the coefficient of \( g_2^{N+2,F}(0, x) \) in Eq. (32) can be simplified in terms of the GES parameter \( \alpha \). Equation (32) has been derived in terms of \( 1/c \) corrections.\[ ^{[30]}\] A detailed calculation of the integral term (in Appendix C) gives

\[ \frac{1}{N^2} \int \cdots \int_{\hat{x}_1 \leq \cdots \leq \hat{x}_{N+2}} (j + 1) dx_1, \ldots, dx_N \frac{\partial}{\partial x_j} \Psi_{N+2}^F(0, x) \]

\[ = \alpha^{N+1} \left( \frac{\partial}{\partial x} g_2^{N+2,F}(0, x) + \frac{\partial}{\partial x} \int_0^x dx_j g_3^{N+2,F}(0, x, x_j) \right), \]

where \( g_2^{N+2,F}(0, x) \) and \( g_3^{N+2,F}(0, x, x_j) \) are the two-body and three-body non-local correlation functions of \( N + 1 \) free fermions, which have been given in Eq. (25). Finally, equation (32) can be viewed as the two-body non-local correlation function of \( N \) particles, namely,

\[ g_k^N(0, x) = \alpha g_2^{N,F}(0, x) + (\alpha - 1)x \frac{\partial}{\partial x} g_2^{N,F}(0, x) \]

\[ + \frac{2}{c} \frac{\partial}{\partial x} g_3^{N,F}(0, x), \]

\[ + \frac{2}{c} \frac{\partial}{\partial x} \int_0^x dx_j g_3^{N+2,F}(0, x, x_j). \]

We observe that the two-body correlation function essentially depends on the two-body and higher order non-local correlation functions of the free fermions and their derivatives, which provide insights into the many-body correlations in strongly interacting bosons.

5. Large momentum tail of the momentum distribution and Tan’s contact relations

Various methods can be used to calculate the contact,\[ ^{[39-41,43-45]} \] for example, it can be obtained from the free energy or ground state energy via the Helmann–Feynmann theorem,\[ ^{[46]} \] or from the single particle correlation function,\[ ^{[47]} \] from the operator product expansion field theory method,\[ ^{[48]} \] etc.

5.1. Large momentum tail of the momentum distribution

The single-particle momentum distribution \( w(p) \) at momentum \( p = \hbar k \) is the Fourier transform of the one-particle density matrix \( \rho(x_j, x_k). \) In order to build up a connection between the Tan’s contact and the power law decay with distance in the large momentum tail of the momentum distribution, we first calculate the wave function in momentum space. To this end, we introduce the center of mass coordinate \( R = (x_j + x_k)/2 \) and relative coordinate \( x_{jk} = x_j - x_k \) of the \( j, k \) pair of particles with other fixed \( N - 2 \) coordinates \( \{x_i\}_{i \neq j, k}. \) The \( k^{th} \) particle in the neighbor of the \( j^{th} \) particle, such as \( x_j \leq x_k \leq x_j \leq \cdots \leq x_{j-1} \leq x_j \leq x_k \leq x_{k-1} \leq \cdots \leq x_N \) and \( x_{j-1} \leq x_k \leq x_j \leq \cdots \leq x_{k-2} \leq x_k \leq x_{j-1} \leq \cdots \leq x_N \), the wave function for 1D strongly interacting bosons in Eq. (3) can be approximately written as

\[ \Psi^B(x_1, \ldots, x_N) = \frac{1}{N!} A(c) \sum_p (-1)^p e^{i(k_{pj} + k_{pj})R} \left( 1 + \frac{i}{2}(k_{pj} - k_{pj})x_{jk} \right) \]

\[ - \frac{1}{8}(k_{pj} - k_{pj})^2 x_{jk}^2 + O(x_{jk}^4) \]  

\[ e^{i\sum_{p,j \neq j} k_{pj} x_{jk}}. \]  

\[ 070306-7 \]
Following symmetric conditions, we can present Eq. (35) in general forms as
\[
\psi^B(x_1, \ldots, x_N)\bigg|_{x_k = x^+_k} \approx \frac{1}{N} \left(1 + \frac{1}{2} \left(\frac{\partial}{\partial x_k} - \frac{\partial}{\partial x_j}\right)\right) |x_{kj}| \text{sgn}(x_{kj}) + \frac{1}{8} \left(\frac{\partial}{\partial x_k} - \frac{\partial}{\partial x_j}\right)^2 |x_{kj}^2| \psi,
\]
(36)
for bosons in the 1D Lieb–Liniger model, where \(\text{sgn}(x) = +1\) for \(x > 0\) and \(-1\) for \(x < 0\), \(\psi\) that corresponds to the wave function Eq. (3) at \(x_k = x^+_k\).

The Fourier transform of the one-particle correlation function is the momentum distribution
\[
w(p) = \int dx \, dx' g_1(x; x') e^{-ip(x-x')},
\]
(37)
where \(p = (2\pi/L)s\) and \(s\) is an integer. This is equivalent to calculating first the many-particle wave function in momentum space for one atom and then integrating out the rest of the coordinates from its square modulus. In order to calculate the asymptotic behavior (the large \(p\) tail) of the momentum distribution, we first consider the normalized wave function with respect to the first particle in momentum space
\[
w^B(p, x_2, \ldots, x_N) = \sum_{k=1}^{N} \frac{1}{\sqrt{L}} \int_0^L dx_k e^{-ipx_k/h} \psi^B(x_1, x_2, \ldots, x_N),
\]
(38)
where \(p = (2\pi/h)L\) with \(l\) an integer. For a repulsive interaction, the diagonal terms become much larger than the off-diagonal terms due to the periodic boundary condition and symmetry. For a periodic function \(F_1(x_1, \ldots, x_N) (x_k - x_1) \text{sgn}(x_k - x_1)\), defined on the interval \([0, L]\), where
\[
F_1(x_1, \ldots, x_N) = \left(\frac{\partial}{\partial x_k} - \frac{\partial}{\partial x_j}\right) \sum_p (-1)^p \exp \left(i \sum_{j=1}^{N} k_p x_j\right)
\]
is a regular function, we thus rewrite the square modulus as
\[
[w^B(p, x_2, \ldots, x_N)]^2 \approx \frac{(N-1)}{N^2} \frac{1}{L^4/p^2} \left(1 + \frac{1}{N} \sum_{j=1}^{N} (2j - N - 1) \left(\frac{\partial}{\partial x_j}\right) \right) \left|F_1(x_1, \ldots, x_N)^2\right|_{x_k = x^+_k} + O\left(\frac{1}{p^2}\right).
\]
(39)
After a length calculation, the asymptotic behavior of the momentum distribution is given by
\[
w(p) \approx \frac{\alpha^2}{L(p/h)^2} \int_0^a dx_k \left(1 + \frac{\alpha}{c} \sum_{j=1}^{N} (2j - N - 1) \left(\frac{\partial}{\partial x_j}\right)^2 \right) \left|F_1(x_1, \ldots, x_N)^2\right|_{x_k = x^+_k},
\]
(40)
where \(g_2^F\) is the fermion two-particle correlation. Upto order \(1/c\), the normalization factor for strongly interacting 1D bosons has been calculated in Ref. [19] as \(N^2 = \alpha^{-N} \int_0^L \ldots \int_0^L dx_1 \ldots dx_N \sum_{j=1}^{N} (-1)^p \exp \left(i \sum_{j=1}^{N} k_p x_j\right) \left|g_2^F\right|_{x_k = x^+_k}^2\).

By applying Wicks theorem and getting partial derivatives, the asymptotic behavior of the momentum distribution becomes
\[
w(p) \approx \frac{g_2^F(0,0)^2}{(p/h)^4} = \frac{4\alpha^2 \pi^2 n^4}{3(p/h)^4} + O\left(\frac{1}{c^2} \frac{1}{(p/h)^5}\right).
\]
(43)
In the above calculation Eq. (42), we have proved that the leading order part gives the universal asymptotic behavior Eq. (43), whereas the second term in Eq. (42) is zero. According to the definition of the momentum distribution, equation (43) is equal to the relation given in Refs. [37] and [36]. Moreover, the Hellmann–Feynman theorem relates to the derivative of the energy with respect to the interacting strength. So we have a two-particle local correlation function \(g_2^F(x_1, x_2) = n^2 e'(\gamma)\)
\[
w(p) \approx \frac{e'(\gamma)n^2\gamma^2}{(p/h)^4},
\]
(44)
where the derivative of total energy \(e'(\gamma) \approx \frac{n^2}{3} \frac{\pi^2 n^4}{3}\). The result of Eq. (43) shows that the tail of the momentum distribution decays with a power of \(1/(p/h)^4\) and it has a sub-leading
contribution determined by the GES parameter $\alpha$.

6. The contact relation

A powerful universal relation connects the strength of short-range two-particle correlations to the thermodynamics of a many-particle system with zero-range interaction. The contact allows for a simple analytic expression that unveils how to scale the momentum distribution function at large momentum. We recall the Lemma discussed in Refs. [36], [46], and [68].

**Lemma 1** Consider a function absolutely integrable, vanishing at infinity which has a singularity of the type $f(x) = |x - x_0|^\alpha F(x)$ at $x_0$ with $F(x)$ analytical and $\alpha > -1, \alpha \neq 0, 2, 4, \ldots$. Then we have

$$\lim_{k \to \infty} \int_{-\infty}^{\infty} e^{-ikx} f(x) \, dx \approx 2 \cos \frac{\pi}{2} (\alpha + 1) \tau(\alpha + 1) \frac{e^{-ikx_0}}{|k|^{\alpha+1}} F(x_0) + O(1/|k|^{\alpha+2}).$$

In the case of multiple singular points of the same type, the asymptotic behavior of the integral is given by the sum of all the corresponding contributions given by the right hand side of Eq. (45).

Considering discontinuity of the derivative wave function, equation (36) is given by

$$\psi^B(x_1, \ldots, x_N) = \frac{1}{N!} \left( 1 - \frac{|x_i|}{a_{1D}} \text{sgn}(x_i) + \frac{2|x_i|}{a_{1D}} + O(x_i)^3 \right) \psi,$$

where $c = -2/a_{1D}$. Applying Lemma 1 to Eq. (46) and after changing integration variables as $dx_1 \sim dx$ and $dx_2 \sim dR$ at $x_1 \to x_k$, we find that the function $\psi$ is a function of $R$ and $X$, where the set of fixed coordinates $X = \{|x_i| = 2, \ldots, k-1, k+1, \ldots, N\}$. Thus we may calculate the expression Eq. (38) as

$$\int \frac{(N-1)}{N^2L} \left[ \frac{1}{\alpha_{1D}} \int_{0}^{L} dx e^{-ipx/h} \right] \left( 1 - \frac{|x|}{a_{1D}} \right) |\psi(R, R, X)|^2 $$

$$= \frac{(N-1)}{N^2L} \left( 4 \frac{a_{1D}}{\alpha_{1D} (p/h)^3} \right) |\psi(R, R, X)|^2.$$  

In the above equation, we have neglected the off-diagonal terms which vanish faster than the diagonal terms. From Eq. (40), the large momentum tail of the momentum distribution is obtained as

$$w(p) \approx \frac{4}{a_{1D} L (p/h)^3} C_2,$$

where the two-particle contact is defined by $C_2 = \int_{0}^{L} dR g_2(R, R)$. Here the two-particle contact is given by $C_2 = 4\pi^2 n \gamma^2 / 3$. Whereas the two-particle local correlation function reads $g_2(0, 0) = 4\pi^2 n^2 \alpha^3 / (3\gamma^2)$ for a finitely strong repulsive Bose gas at zero temperature, further confirming Eq. (11). This result agrees with that derived by Yuta et al. in Ref. [52]. Moreover, in a weakly coupling regime, the two-particle local correlation function is given by $g_2(0, 0) = n^2 (1 - 2\sqrt{1/\pi})$. So the two-particle contact can be obtained as $C_2 = nN (1 - 2\sqrt{1/\pi})$ for the 1D weakly interacting bosons.

7. Static structure factor

The structure factor is a property that defines how an ensemble of atoms scatters incident radiation. Experimentally, it is usually measured by two-photon Bragg scattering. Due to the translational invariance of the system, the density is constant, the static structure factor is defined as

$$S(k) = 1 + \frac{1}{N} \int dx_k \int dx_j e^{-ik(x_k - x_j)} \times (g_2(x_k, x_j) - n(x_k)n(x_j)),$$

where $n(x_i)$ is the density. Changing the integration variables as before, we have

$$S(k) = 1 + \frac{1}{N} \int_{0}^{L} dx \int_{0}^{L} dR e^{-ikx} \left( 1 - \frac{2|x|}{a_{1D}} \right) g_2(R, R^+) - n^2$$

$$= 1 + \frac{4}{Na_{1D}k^2} C_2,$$

where $C_2 = \int_{0}^{L} dR g_2(R, R^+)$, also see Ref. [52]. By using Eq. (25), the two-particle non-local correlation function of the 1D Bose gas in the strongly interacting regime, i.e. $c \to \infty$, is given by

$$g_2(R, R^+) \approx n^2 \left( 1 - \left( \frac{\text{sin}(kF)}{kFx} \right)^2 \right).$$

Here, $x$ and $k^F = \pi n$ are the relative coordinate and the cut-off Fermi momentum, respectively. Thus the structure factor can be determined by Eq. (50), namely,

$$S(k) = \begin{cases} 1, & \text{for } |k| > 2k^F; \\ \frac{|k|}{2k^F}, & \text{for } |k| < 2k^F. \end{cases}$$

In fact, in the low-momentum and the infinitely repulsive regime, the static structure factor has a linear dependence of $k$. In the TG regime, this behavior converts to $S(k) = |k|/2k^F$. For high momentum, the structure factor always converges to 1.

8. Conclusion

In summary, we have presented a pedagogical study of various higher order local and non-local correlation functions.
of 1D Lieb–Liniger Bose gas. Using the Bethe wave function, we have studied the non-local 2M point correlation functions and the large momentum tail of the momentum distribution in term of the fractional statistical parameter $\alpha$ for the system with a strong repulsion. We have also discussed the higher-order correlation functions for the weakly interacting Bose gas via the Bethe ansatz wave function. It turns out that the leading order of the large-momentum tail is determined by the contact, which is related to the short-distance behavior of the two-body density matrix. The two-body density matrix has been given in term of the fractional statistical parameter $\alpha$, giving the subleading order $1/c$ correction in the strong coupling regime, where the interaction strength $c \gg 1$. Our results show that the fractional statistical parameter $\alpha$ attributes to the sub-leading contributions of the local, non-local correlation functions, two-body contact, static structure factor, etc. Our method is applicable to other exactly solvable models.

Acknowledgment

We thank Xiaoguo Yin, Yu-Zhu Jiang, Shina Tan for helpful discussion.

Appendix A

The Betha ansatz wave function given in Eq. (2)
\[
\psi(x_1, \ldots, x_N) = \sum (-1)^P \prod_{1 \leq i < j \leq N} \left( \frac{ic + k_{p_1} - k_{p_2}}{ic - k_{p_1} + k_{p_2}} \right) \frac{1}{2} \right)^{i \sum p_j x_j} e^{\sum k_j x_j}. \tag{A1}
\]

Using the Bethe ansatz equation, we have
\[
(-1)^{P_0}A(P) \equiv (-1)^P \prod_{i < j} \left( \frac{ic + k_{p_1} - k_{p_2}}{ic - k_{p_1} + k_{p_2}} \right)^{1/2} \equiv (-1)^P \prod_{i < j} \left( -2\tan^{-1}\left( \frac{k_{p_2} - k_{p_1}}{c} \right) \right)^{1/2}
\]
\[
= \exp \left( i \frac{\pi}{2} (1 - (-1)^P) + \frac{i}{2} \sum_{i < j} \left[ -\frac{q_i - q_j}{|q_i - q_j|} \pi + \sqrt{2cL} F(q_i - q_j) \right] \right) . \tag{A2}
\]

Furthermore we consider the following relation
\[
\arctan(x) + \arctan(1/x) = \begin{cases} \pi/2, & \text{for } x > 0, \\ -\pi/2, & \text{for } x < 0. \end{cases} \tag{A3}
\]

Then, we have
\[
\theta(k_i - k_j) = -2\tan^{-1}\left( \frac{k_i - k_j}{c} \right) = -\frac{(k_i - k_j)}{k_i - k_j} \pi + \frac{2c}{k_i - k_j} . \tag{A4}
\]

Take \( q_j = \sqrt{\frac{L}{2c}} k_j \),
\[
\theta(k_i - k_j) = \theta\left( \sqrt{\frac{2c}{L}} (q_i - q_j) \right) = -\frac{(q_i - q_j)}{|q_i - q_j|} \pi + \sqrt{2cL} F(q_i - q_j) . \tag{A5}
\]

where $F(q_i - q_j) = (q_i - q_j)^{-1}$. Therefore, equation (A2) becomes
\[
(-1)^{P_0}A(P) = \exp \left( i \frac{\pi}{2} (1 - (-1)^P) + \frac{i}{2} \sum_{i < j} \left[ -\frac{(q_i - q_j)}{|q_i - q_j|} \pi + \sqrt{2cL} F(q_i - q_j) \right] \right) . \tag{A6}
\]

Using Eq. (A6), we consider the two permutations of the system with 3 particles
\[
(-1)^{P_0}A(123) = \exp \left( i \frac{\pi}{2} (1 - (-1)^P) + \frac{i}{2} \sum_{i < j} \left[ -\frac{(q_i - q_j)}{|q_i - q_j|} \pi + \sqrt{2cL} F(q_i - q_j) \right] \right) = \exp \left( i \frac{\pi}{2} \sqrt{\frac{2cL}{2}} \left[ F(q_2 - q_1) + F(q_3 - q_1) + F(q_1 - q_3) \right] \right) . \tag{A7}
\]

\[
(-1)^{P_0}A(213) = \exp \left( i \frac{\pi}{2} (1 - (-1)^P) + \frac{i}{2} \sum_{i < j} \left[ -\frac{(q_i - q_j)}{|q_i - q_j|} \pi + \sqrt{2cL} F(q_i - q_j) \right] \right) = \exp \left( i \frac{\pi}{2} \sqrt{\frac{2cL}{2}} \left[ F(q_1 - q_2) + F(q_3 - q_2) + F(q_1 - q_3) \right] \right) . \tag{A8}
\]

Therefore, the general form of amplitude with permutation’s sign of the wave function in the weak coupling regime can be obtained as
\[
(-1)^{P_0}A(p) = \exp \left( i \sqrt{\frac{2cL}{2}} \sum_{i < j} \left[ F(q_i - q_j) \right] \right) . \tag{A9}
\]
Finally, we rewrite the Bethe ansatz wave function Eq. (3) in the weak coupling regime as

$$
\psi(x_1, \ldots, x_N) = \sum_P \exp \left( i \frac{cL}{2} \sum_{i<j} \left( \sqrt{2c/L} F(q_{P_i} - q_{P_j}) + \sqrt{2c/L} \sum_{j=1}^N q_{P_{jx}} \right) \right) 
\times \exp \left( i \frac{cN}{2} \sum_{j=1}^N \sqrt{2c/L} q_{P_j} \right)
= \sum_P \left[ 1 + i \left( \frac{cL}{2} \sum_{i<j} F(q_{P_i} - q_{P_j}) + \sqrt{2c/L} \sum_{j=1}^N q_{P_{jx}} \right) \right] 
- \frac{1}{2} \left( \frac{cL}{2} \sum_{i<j} F(q_{P_i} - q_{P_j}) + \sqrt{2c/L} \sum_{j=1}^N q_{P_{jx}} \right)^2 + \cdots 
= N! - \frac{c}{2} Y(x_1, \ldots, x_N), \tag{A10}
\]}

where

$$
Y(x_1, \ldots, x_N) = \sum_P \left( \sqrt{\frac{L}{2}} \sum_{i<j} F(q_{P_i} - q_{P_j}) + \sqrt{\frac{2c}{L}} \sum_{j=1}^N q_{P_{jx}} \right)^2,
$$

since the symmetric condition gives $\sum_P \sum_{i<j} F(q_{P_i} - q_{P_j}) = 0$

and $\sum_P \sum_{j=1}^N q_{P_j} = 0$.

**Appendix B**

Let us represent the field operator $\hat{\Psi}$ as a sum of the condensate part $\psi_0$ and a non-condensate part $\psi'$,

$$
\hat{\Psi} = \psi_0 + \psi'. \tag{B1}
$$

In the uniform case, we may let the condensate contain a macroscopic number of particles $N_0$. Consider the density of the system is $n = n_0 + n'$, where $n_0 = \langle \psi_0 \psi_0^\dagger \rangle = |\psi_0|^2$ is the condensed particles density and $n' = \langle \psi'^\dagger \psi' \rangle$ is the non-condensed particles density. Considering the $M$th order density of the system with respect to the first order of $\psi'$, we have

$$
n^M = (|\psi_0|^2)^M + M(|\psi_0|^2)^{M-1} \langle \psi'^\dagger \psi' \rangle + O(|\psi'^\dagger \psi'|^2), \tag{B2}
$$

$$
\Rightarrow \langle \psi'^\dagger \psi' \rangle = \frac{n^M}{M |\psi_0|^2} - M |\psi_0|^2 \langle \psi'^\dagger \psi' \rangle = n^M - Mn_0^{M-1} \langle \psi'^\dagger \psi' \rangle + O(|\psi'^\dagger \psi'|^2). \tag{B3}
$$

The $M$ particle correlation function for 1D bosons at weak coupling limit reads

$$
\mathcal{g}_M^{\psi'} = \langle (\psi_0^\dagger + \psi'^\dagger)^M (\psi_0 + \psi')^M \rangle. \tag{B4}
$$

Expanding the $M$th order in Eq. (B4) and substituting Eq. (B3) into the above equation, we obtain

$$
\mathcal{g}_M^{\psi'} = \langle (\psi_0^M + M\psi_0^{M-1}\psi')^M \psi'^\dagger \psi' + \frac{1}{2} M(M-1) \psi_0^{M-2} \psi'^\dagger \psi'^\dagger + O(\psi'^\dagger \psi'^\dagger)^2 \rangle
+ \frac{1}{2} M(M-1) \psi_0^{M-2} \psi'^\dagger \psi'^\dagger + O(\psi'^\dagger \psi'^\dagger)^2 \rangle
= \langle |\psi_0|^2 + M |\psi_0|^2 \langle \psi'^\dagger \psi' \rangle + M(M-1) |\psi_0|^2 \langle \psi'^\dagger \psi' \rangle \rangle
+ M(M-1) |\psi_0|^2 \langle \psi'^\dagger \psi' \rangle \rangle
= n^M \left( 1 + \frac{M(M-1)}{n} \langle \psi'^\dagger \psi' \rangle \right). \tag{B5}
$$

Equation (B5) shows that $\mathcal{g}_M^{\psi'}$ depends on the normal density of non-condensated particles, $\langle \psi'^\dagger \psi' \rangle$, and anomalous density of non-condensated particles $\langle \psi'^\dagger \psi' \rangle$. Consider the form of non-condensate part $\psi'$ as

$$
\psi' = \sum_v (u_v \hat{b}_v e^{-i\epsilon_v t/h} - v_v \hat{b}_v^\dagger e^{i\epsilon_v t/h}), \tag{B6}
$$

which is known as Bogoliubov transformation. Here the index $v$ labels quantum states of elementary excitations, $\hat{b}_v, \hat{b}_v^\dagger$ are operators of excitations, $\epsilon_v$ are their eigenenergies, and $u_v, v_v$ their eigen functions. The operators $\hat{b}_v$ and $\hat{b}_v^\dagger$ obey the usual boson commutation relations

$$
\hat{b}_v \hat{b}_v^\dagger - \hat{b}_v^\dagger \hat{b}_v = \delta_{vv'}, \quad \hat{b}_v \hat{b}_v' - \hat{b}_v' \hat{b}_v = 0. \tag{B7}
$$

The functions $u_v$ and $v_v$ are normalized by the condition

$$
\int (u_v u_v^\dagger - v_v v_v^\dagger) dx = \delta_{vv'}. \tag{B8}
$$

Taking into account that the index $v$ is now the excitation wave vector $k$, we write the excitation wave function in the form $u_v = \frac{u_k}{\sqrt{L}} e^{i k x}$ and $v_v = \frac{v_k}{\sqrt{L}} e^{i k x}$. Consequently, we have

$$
\langle \psi'^\dagger \psi' \rangle = \frac{1}{L} \sum_k \left[ u_k^2 N_k + \frac{v_k^2}{2} (1 + N_k) \right]. \tag{B9}
$$

The normal and anomalous densities of the non-condensate part can be calculated by using Eq. (B9) at $k = k'$ as

$$
\langle \psi'^\dagger \psi' \rangle = \frac{1}{L} \sum_k \left[ u_k^2 N_k + \frac{v_k^2}{2} (1 + N_k) \right], \tag{B10}
$$

$$
\langle \psi'^\dagger \psi' \rangle = \frac{1}{L} \sum_k \left[ - u_k v_k (1 + N_k) - v_k^2 u_k N_k \right], \tag{B11}
$$

where $N_k$ is the occupation number for the excitations with $N_k \to 0$ as $T \to 0$ and commutation relations of the excitation operators are $\langle \hat{b}_k^\dagger \hat{b}_0 \rangle = \delta_{kk} \xi_k N_k, \quad \langle \hat{b}_k^\dagger \hat{b}_k \rangle = \delta_{kk} (1 + N_k)$, and $\langle \hat{b}_k \hat{b}_0 \rangle = \langle \hat{b}_k^\dagger \hat{b}_0^\dagger \rangle = 0$. Summation of Eq. (B10) and Eq. (B11) gives

$$
\langle \psi'^\dagger \psi' \rangle + \langle \psi'^\dagger \psi' \rangle = \frac{1}{L} \sum_k \left[ u_k^2 N_k + \frac{v_k^2}{2} (1 + N_k) - u_k v_k (1 + 2N_k) \right], \tag{B12}
$$

since $v_k^2 = v_k$. By considering up to the linear order of $\psi'$ of field operator Eq. (B1), the Gross–Pitaevskii equation can be obtain as

$$
i\hbar \frac{\partial \psi'}{\partial t} = \left( -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + 2g|\psi_0|^2 - \mu \right) \psi' + \mathcal{g}_M^{\psi'} \psi'. \tag{B13}
$$
The non-condensate density yields from the eigenfunctions $u_k$ and $v_k$. In order to find $u_k$ and $v_k$, evaluating the commutator of both sides of Eq. (B13) with $\hat{b}_k$ and repeating procedure with $\hat{b}_k^\dagger$, one can obtain

$$-\epsilon_k v_k = \left(\frac{\hbar^2 k^2}{2m} + 2g|\psi_0|^2 - \mu\right)v_k - g\psi_0^2 u_k,$$

(B14)

$$\epsilon_k u_k = \left(\frac{\hbar^2 k^2}{2m} + 2g|\psi_0|^2 - \mu\right)u_k - g\psi_0^2 v_k.$$  

(B15)

Here, $\nu^* = \nu$ and $\nu^* = \nu$. Substituting $\mu = mg$ and $E_k = \frac{\hbar^2 k^2}{2m}$ to Eqs. (B14) and (B15), which are called Bogoliubov–de Gennes equations for elementary excitations, they are transformed to

$$\epsilon_k v_k = (E_k + gn) v_k - gmn u_k,$$

(B16)

$$\epsilon_k u_k = (E_k + gn) u_k - gmn v_k.$$  

(B17)

After taking difference between squares of Eqs. (B16) and (B17), applying the normalization condition given by Eq. (B8), $|u_k|^2 - |v_k|^2 = 1$, then we obtain the excitation energy

$$\epsilon_k = \sqrt{E_k^2 + 2gmnE_k}.$$  

(B18)

Taking a summation of Eqs. (B16) and (B17) gives

$$u_k = \frac{(E_k + \epsilon_k) v_k}{\epsilon_k - \epsilon_{\bar{k}}}.$$  

(B19)

Applying $|u_k|^2 - |v_k|^2 = 1$ to Eq. (B19) gives

$$v_k = \frac{(\epsilon_k - E_k)^2}{4E_k \epsilon_k}.$$  

(B20)

From Eqs. (B19) and (B20), we finally obtain

$$v_k = \pm \frac{1}{2} \left(\frac{E_k}{\epsilon_k} - \sqrt{\frac{E_k}{\epsilon_k}}\right).$$

(B21)

Substituting Eq. (B21) into Eq. (B12), and solving the summation of normal and anomalous densities, then we have

$$\langle \psi^* \psi \rangle + \langle \psi' \psi' \rangle = \frac{1}{L} \sum_k \left[\frac{E_k}{\epsilon_k} (N_k + \frac{1}{2}) - \frac{1}{2}\right].$$

(B22)

Equation (B23) consists quantum vacuum fluctuations and thermal fluctuations of the system. At zero temperature, all particles are in the condensate, i.e., $N_k = 0$ at $t = 0$ and $N_k \neq 0$ for finite temperature. Therefore, the density of non-condensate can be represented as

$$\langle \psi^* \psi \rangle + \langle \psi' \psi' \rangle|_{\text{total}} = \langle \psi^* \psi \rangle|_{T = 0} + \langle \psi' \psi' \rangle|_{T \neq 0} = \frac{1}{L} \sum_k \left[\frac{E_k}{\epsilon_k} (N_k + 1) - 1\right].$$

(B23)

From Eq. (B5), the $M$ body correlation function at weak coupling regime is

$$g_{MN}^M = n^M \left(1 + \frac{M(M-1)}{2\pi n} \int_{-\infty}^\infty dk \left[\frac{E_k}{\epsilon_k} (N_k + 1) - 1\right]\right).$$

(B24)

**Appendix C**

Consider the integral term in Eq. (32). There are $j$ points between 0 and $x$ and $N - j$ points between $x$ and $L$. Among the $(N + 2)$ particles. Here we present the calculation of the following form of the integration:
\[
\begin{align*}
&= \frac{1}{N^2} \frac{\partial}{\partial x} \left[ \sum_{j=1}^{N} \int_{x_j}^{x} dx_j |\Psi_{N+1}^{F}|^2 + \sum_{j=1}^{N} \int_{x_j}^{x} dx_j |\Psi_{N+2}^{F}|^2 \right] \Big|_{\xi=1} \\
&= \frac{1}{N^2} \frac{\partial}{\partial x} \left[ \prod_{j=1}^{N} \int_{x_j}^{x} dx_j |\Psi_{N+1}^{F}|^2 + \frac{\partial}{\partial x} \sum_{j=1}^{N} \int_{x_j}^{x} dx_j |\Psi_{N+2}^{F}|^2 \right] \\
&= \alpha^{N+1} \left( \frac{\partial}{\partial x} \delta_{2N+2,F}(0,x) + \frac{\partial}{\partial x} \sum_{j=1}^{N} \int_{x_j}^{x} dx_j |\Psi_{N+2}^{F}(0,x,x_j)| \right),
\end{align*}
\]
(C1)

where we can write
\[
\prod_{j=1}^{N} \left( \int_{x_j}^{x} + \xi_{j} \int_{0}^{x} \right) dx_j |\Psi_{N}^{F}|^2 = \sum_{j=0}^{N} \left( \frac{N!}{j!(N-j)!} \right) \prod_{j=1}^{N} \int_{x_j}^{x} dx_j |\Psi_{N}^{F}|^2.
\]
(C2)

What below gives a further demonstration on spacial cases, see Eqs. (C3) and (C4). Consider a system with \(N = 3\),
\[
\prod_{j=1}^{3} \left( \int_{x_j}^{x} + \xi_{j} \int_{0}^{x} \right) dx_j |\Psi_{3}^{F}|^2
\]
\[
= \left[ \int \int \int dx_1 dx_2 dx_3 + \left( \int \int dx_1 dx_3 \xi \int_0^x dx_2 + \int \int dx_2 dx_3 \varsigma \int_0^x dx_1 + \int \int dx_1 dx_2 \xi \int_0^x dx_3 \right) \right. \\
+ \left. \left( \int \int dx_1 dx_3 \xi^2 \int_0^x dx_1 dx_2 + \int \int dx_2 dx_3 \varsigma^2 \int_0^x dx_1 dx_3 + \int \int dx_1 dx_2 \xi^2 \int_0^x dx_1 dx_3 \right) \right] |\Psi_{3}^{F}|^2,
\]
(C3)
\[
\sum_{j=0}^{3} \left( \frac{3!}{j!(3-j)!} \right) \prod_{j=1}^{3} \int_{x_j}^{x} dx_j |\Psi_{3}^{F}|^2
\]
\[
= \left[ \int \int \int dx_1 dx_2 dx_3 + \left( \xi \int_0^x dx_1 \int \int dx_2 dx_3 + \xi \int_0^x dx_2 \int \int dx_1 dx_3 + \xi \int_0^x dx_3 \int \int dx_1 dx_2 \right) \right. \\
+ \left. \left( \xi^2 \int_0^x dx_1 dx_2 \int \int dx_3 + \xi^2 \int_0^x dx_2 \int \int dx_1 dx_3 + \xi^2 \int_0^x dx_3 \int \int dx_1 dx_2 \right) \right] |\Psi_{3}^{F}|^2.
\]
(C4)
