The Yamabe flow on asymptotically flat manifolds

Eric Chen∗ Yi Wang†

Abstract

We study the Yamabe flow starting from an asymptotically flat manifold \((M^n, g_0)\). We show that the flow converges to an asymptotically flat, scalar flat metric in a weighted global sense if \(Y(M, [g_0]) > 0\), and show that the flow does not converge otherwise. If the scalar curvature is nonnegative and integrable, then the ADM mass at time infinity drops by the limit of the total scalar curvature along the flow.

1 Introduction

In this article we study the long-time existence and convergence of the Yamabe flow

\[
\begin{aligned}
\frac{\partial g}{\partial t} &= -Rg, \\
g(0) &= g_0,
\end{aligned}
\]

starting from an asymptotically flat manifold \((M^n, g_0)\). Here \(R\) denotes the scalar curvature of the Riemannian metric \(g = g(t)\). This flow preserves the conformal class of \(g\) and is the natural analogue of the volume-normalized Yamabe flow on compact manifolds introduced by Hamilton [Ham89]. He was motivated by the resolution of the Yamabe problem due to Yamabe, Trudinger, Aubin, and Schoen [Yam60; Tru68; Aub76; Sch84], which showed that every conformal class of Riemannian metrics on a compact manifold admits at least one metric of constant scalar curvature, known as a Yamabe metric, which minimizes the Einstein–Hilbert functional. Hamilton proposed the volume-normalized Yamabe flow, which can be viewed as the gradient flow of the Einstein–Hilbert functional within a fixed conformal class, as a natural evolution equation which could potentially evolve a given metric on a compact manifold to one of constant scalar curvature within the same conformal class.

Hamilton was already able to prove the long-time existence of the volume-normalized Yamabe flow on compact manifolds when he introduced it. Convergence of the flow to a metric of constant scalar curvature has now been mostly

settled by work of Ye, Schwetlick–Struwe, and Brendle \cite{Ye94, SS03, Bre05, Bre07}.

The study on noncompact manifolds is less developed, but there have been a number of long-time existence results for the flow \eqref{1.1}. For complete noncompact manifolds, Ma has shown long-time existence when starting from a metric of non-negative scalar curvature which is conformal to a metric of non-positive scalar curvature, assuming the corresponding conformal factor is bounded from above \cite{Ma19}. Schulz has shown long-time existence existence under related hypotheses — namely when starting from a metric of positive Yamabe constant which is conformal to a metric of non-positive and bounded scalar curvature, assuming the corresponding conformal factor is bounded both from above and from below \cite{Sch19}. Other works give long-time existence results in the settings of conformally hyperbolic and singular spaces \cite{Sch20, BV19, LV20}. Similar to the compact case, convergence results for \eqref{1.1} have been slower to develop — we are aware only of Ma’s work mentioned above \cite{Ma19} in which he is also able to show $C^\infty_{\text{loc}}$ convergence to a scalar flat limit metric, using crucially the assumption of initially non-negative scalar curvature.

Our work adds to the study of \eqref{1.1} in the non-compact case by providing a long-time existence result in the setting of asymptotically flat manifolds without requiring any additional curvature assumptions, and by showing that the flow in this setting converges in a strong, global weighted sense (in $C^\infty_{\text{loc}}$) to a scalar flat, asymptotically flat metric whenever one might hope for this — namely whenever there exists a scalar flat, asymptotically flat metric lying in the conformal class of the initial metric. Asymptotically flat metrics are interesting to study under Yamabe flow because as shown by Cheng–Zhu, who were motivated by similar results in the Ricci flow setting \cite{DM07}, asymptotic flatness is preserved under the Yamabe flow and moreover the ADM mass is monotonically decreasing \cite{CZ15}. As a consequence of our convergence results, the drop from the ADM mass along the flow to the mass of the limiting scalar flat metric is accounted for by the total scalar curvature pushed out to spatial infinity by the flow.

While we were completing this manuscript we learned of recent new work by Ma \cite{Ma21} in some directions similar to ours. His result considers the long-time existence of the flow, which overlaps with some of the content in our Lemma \ref{3.4} and its corollary Theorem \ref{1.1}. But the focus of our paper is to prove the strong global $C^\infty_{\text{loc}}$ convergence when $Y(M^n, [g_0]) > 0$. Towards this goal, the central issue is the sufficiently fast decay rate estimate of $\|R\|_{L^p}$, which we achieve in several steps. One of the first observations is the monotonicity of the integral $\|R\|_{L^p}$ for $p = n/2$. This allows us to prove that $\|R\|_{L^p}$ tends to zero as $t \to \infty$ for $p$ in a neighborhood of $n/2$. Another key step is to obtain the convergence of $\|R\|_{L^\infty}$ at a particular decay rate using the Moser iteration. With these, we finally conclude $\|R\|_{L^\infty} \leq O(t^{-1-\delta})$ — here $\delta > 0$ is essential as the integrability of $\int_0^\infty \|R\|_{L^\infty} \, dt$ leads to the unweighted and weighted convergence of the flow in Section 5. To better understand the complete picture, we also study the flow when $Y(M^n, [g_0]) \leq 0$. In this remaining case, we exclude the possibility of convergence.
### 1.1 Main results

Below we describe our main results. The definition of a $C^{k+\alpha}_{-\tau}$ asymptotically flat (AF) manifold below is the same as in \cite{CZ15, Ma19} and this along with related notions of weighted Hölder and Sobolev spaces are stated precisely in Section 2.1.

Our first result is the long-time existence of the Yamabe flow on all AF manifolds. On the order of asymptotic flatness we always assume that $\tau > 0$.

**Theorem 1.1.** Given any $C^{k+\alpha}_{-\tau}$ AF manifold $(M^n, g_0)$, $k \geq 2$, there exists a Yamabe flow starting from it defined for all positive times with $(M^n, g(t))$ remaining $C^{k+\alpha}_{-\tau'}$ asymptotically flat for all $\tau' \leq \min\{\tau, n-2\}$.

We will not be concerned in this work with the uniqueness of Yamabe flow in the AF setting; above, Theorem 1.1 refers to any fine solution of the Yamabe flow whose short-time existence on AF manifolds was shown in \cite[Corollary 2.5]{CZ15} — see Definition 2.3 for details. These are always the solutions which we study in this work, but below we will often write the Yamabe flow with this meaning implicit for ease of presentation.

The special case $R_{g_0} \geq 0$ of Theorem 1.1 was previously known from work of Ma \cite[Theorem 1]{Ma19}, while work of Schulz implies the case $Y(M, [g_0]) > 0$ \cite[Theorem 1]{Sch19}. As mentioned earlier, while we were preparing this manuscript we also learned of recent work of Ma \cite{Ma21} establishing the $C^{2+\alpha}_{-\tau}$ version of the long-time existence result of Theorem 1.1.

Here, $Y(M, [g_0])$ denotes the following conformally invariant quantity which we call the Yamabe constant, motivated by the definition of the Yamabe constant in the compact case:

$$Y(M, [g_0]) := \inf_{v \in C_0^\infty(M), \ v \neq 0} \frac{4^{\frac{n-2}{2}} \int_M |\nabla v|^2 + R_{g_0} v^2 \ dV_{g_0}}{\left( \int |v|^{\frac{2n}{n-2}} \ dV_{g_0} \right)^{\frac{n}{n-2}}}$$

which plays an important role in the prescribed scalar curvature problem on conformal classes of AF metrics \cite{CB81, Max03, DM18}. For instance, by \cite[Proposition 3]{Max03}, which gives the correct version of a result first claimed in \cite[Theorem 2.1]{CB81}, the conformal class $(M, [g_0])$ admits a scalar flat, AF metric if and only if it is Yamabe-positive — we state a version of this result in Proposition 3.2 below.

Having obtained long-time existence of the Yamabe flow on AF manifolds, we next study its convergence properties. On compact manifolds, proving the convergence of the Yamabe flow required much more work than proving long-time existence — see \cite{Ye94, SS03, Bre07, Bre07}. In our setting, if the conformal class $(M, [g_0])$ admits a scalar flat, asymptotically flat metric (which must be unique), this gives additional information with which we are able to obtain strong quantitative decay of the scalar curvature. By our earlier discussion, we can equivalently formulate such a condition in terms of the positivity of $Y(M, [g_0])$, and we have two distinct possibilities for the behavior of the flow as $t \to \infty$ as below.
**Theorem 1.2.** Let \((M^n, g_0)\) be a \(C^{k+\alpha}_\tau\) AF manifold with \(k \geq 3\).

1. If \(Y(M^n, [g_0]) > 0\), then the Yamabe flow \((M^n, g(t))\) starting from \((M^n, g_0)\) converges uniformly in \(C^{k+\alpha}_0\) to the unique \(C^{k+\alpha}_\tau\) AF metric \(g_\infty \in [g_0]\) as \(t \to \infty\).

2. If \(Y(M^n, [g_0]) \leq 0\), then the Yamabe flow \((M^n, g(t))\) starting from \((M^n, g_0)\) does not converge. In particular, \(g(t) = u(t)^{-\frac{4}{n-2}} g_0\) will fail to remain uniformly equivalent to \(g_0\) as \(t \to \infty\), and both \(\|u(t)\|_{L^\infty}\) and the \(L^2\) Euclidean-type Sobolev constant of \(g(t)\) will tend to positive infinity.

The second part of Theorem 1.2 raises the question of what more can be determined regarding the non-convergence along the Yamabe flow on a large class of AF manifolds. In the compact case, Schwetlick–Struwe showed that a failure of convergence must imply a particular kind of infinite time bubbling behavior for the volume-normalized Yamabe flow [SS03]. In the non-compact, conformally flat setting Choi–Daskalopoulos have produced examples of Yamabe flows with infinite-time Type II singularities, which satisfy \(\sup_{M \times [0, \infty)} |\text{Rm}(x, t)| = \infty\) [CD18]. Finite-time singularities in the non-compact, conformally flat setting have also been studied in [CDK18; DKS19].

The first part of Theorem 1.2 above gives a uniform global convergence which is strong enough to allow us to identify the limiting metric \(g_\infty\). If we impose some mild restrictions on the decay order \(\tau\) (which are natural for instance if we wish to consider the ADM mass under the flow), then we can further improve to weighted convergence in Theorems 1.3 and 1.4 below.

**Theorem 1.3.** Let \((M^n, g_0)\) be a \(C^{k+\alpha}_\tau\) AF manifold with \(Y(M^n, [g_0]) > 0\), \(k \geq 3\), and \(\tau > 1\). Then there exists a Yamabe flow \((M^n, g(t))\) starting from \((M^n, g_0)\) defined for all positive times and a metric \(g_\infty\) on \(M^n\) which is \(C^{k+\alpha}_{\tau'}\) AF for all \(\tau' < \min\{\tau, n-2\}\) so that for any such \(\tau'\) we have

\[
\|g(t) - g_\infty\|_{C^{k+\alpha}_{\tau'}} = O(t^{-\delta_0}), \quad \text{as } t \to \infty,
\]

for some \(\delta_0 > 0\). In particular, this Yamabe flow converges in \(C^{k+\alpha}_{\tau'}\) to the asymptotically flat, scalar flat metric \(g_\infty\).

As noted earlier, the work of Cheng–Zhu shows that under appropriate initial conditions, the ADM mass of an asymptotically flat manifold with non-negative and integrable scalar curvature is nonincreasing under Yamabe flow [CZ15, Theorem 1.5], which suggests further study of the mass along the flow. Theorem 1.3 will suffice for this purpose when \(n \geq 4\), since mass is well-defined for \(\tau > \frac{n-2}{2} \geq 1\); however, when \(n = 3\) the condition \(\tau > 1\) forces the mass to vanish and is too restrictive.

However, by adding the natural conditions \(R_{g_0} \geq 0\) and \(R_{g_0} \in L^1\) (if we are concerned with the mass) we can still obtain a weighted convergence result that will allow us to study the mass in dimension \(n = 3\).
Theorem 1.4. Let \((M^n, g_0)\) be a \(C^{k+\alpha}_{-\tau} \) AF manifold with \(Y(M, [g_0]) > 0\), \(k \geq 3\), \(\tau > \frac{1}{2}\), \(R_{g_0} \geq 0\), and \(R_{g_0} \in L^1\). Then there exists a Yamabe flow \((M^n, g(t))\) starting from \((M^n, g_0)\) defined for all positive times and a metric \(g_\infty\) on \(M^n\) which is \(C^{k+\alpha}_{-\tau} \) AF for all \(\tau' < \min\{\tau, 1\}\) so that for any such \(\tau' \) we have

\[
\|g(t) - g_\infty\|_{C^{k+\alpha}_{-\tau'}} = O(t^{-\delta_0}), \quad \text{as} \ t \to \infty,
\]

for some \(\delta_0 > 0\). In particular, this Yamabe flow converges in \(C^{k+\alpha}_{-\tau'}\) to the asymptotically flat, scalar flat metric \(g_\infty\).

It is well-known that \(m(g_0) \geq m(g_\infty)\), since a scalar flat AF metric minimizes the mass among scalar nonnegative metrics within its conformal class \([SY79]\), and one can moreover compute this difference as a multiple of the integral of \(R_{g_0}\) against \(u_\infty\) with respect to the volume form of \(g_0\), where \(g_\infty = \frac{u_\infty}{u_\infty}\). By our weighted convergence results in Theorems 1.3 and 1.4 combined with the monotonicity of mass along Yamabe flow \([CZ15]\) and the lower semicontinuity of the ADM mass under \(C^2_{-\tau}\) convergence when \(\tau > \frac{2n-2}{n-1}\) \([Li18; MS12, Theorem 14; Jau19, Theorem 13]\), this difference is also the mass drop at time infinity of the Yamabe flow starting from \((M^n, g_0)\), and is therefore controlled by the \(L^1\) norm of the scalar curvature as it escapes to infinity.

Corollary 1.5. For \(n \geq 3\), let \((M^n, g_0)\) be a \(C^{k+\alpha}_{-\tau} \) AF manifold with non-negative scalar curvature and \(k \geq 3\), \(\tau > \frac{2n-2}{n-1}\), along with \(R_{g_0} \in L^1(M^n, g_0)\). Then along the Yamabe flow \((M^n, g(t))\) starting from \((M^n, g_0)\),

\[
\lim_{t \to \infty} \left( m(g(t)) - \frac{1}{2(n-1)\omega_{n-1}} \int R_{g(t)} \ dV_t \right) = m(g_\infty). \tag{1.5}
\]

In particular if \(n = 3, 4, \) or \(5\) or if \(\tau > n-3\) so that \(m(g(t))\) is constant along the flow, then

\[
m(g_0) - m(g_\infty) = \frac{1}{2(n-1)\omega_{n-1}} \lim_{t \to \infty} \int R_{g(t)} \ dV_t. \tag{1.6}
\]

Since for any compact region \(K \subset M\), \(\lim_{t \to \infty} \int_K R_{g(t)} \ dV = 0\), we see in \([Li00]\) that along the Yamabe flow, the difference between the initial mass and the limit mass is accounted for by the total scalar curvature pushed out to infinity by the flow. Such a phenomenon has also been shown by Li to occur for the Ricci flow on asymptotically flat spaces if long-time existence is assumed \([Li18]\).

We also note that although \([CZ15]\) does not show that the mass is constant along the Yamabe flow in general when \(n = 5\), our convergence results give us additional curvature control that allows us to deduce this as well from their arguments.

1.2 The main technical estimates

Theorem 1.1 is proved straightforwardly from a maximum principle argument using a result of Dilts–Maxwell which states that one can prescribe any strictly
negative scalar curvature in the conformal class of AF metrics associated to any asymptotically flat \((M^n, g_0)\) along with standard parabolic regularity theory. The bulk of the paper which follows is devoted to the proof of Theorems 1.2, 1.3, and 1.4.

To prove our convergence results in Theorems 1.2, 1.3, and 1.4 we will need to establish the decay of scalar curvature at suitably fast rates. Towards this purpose we again start with bounds on the conformal factor \(u(x,t)\) along Yamabe flow using the assumption that there exists a scalar flat, AF metric in the conformal class \((M, [g_0])\) (or equivalently, that \(Y(M, [g_0]) > 0\)), which gives us enough control to conclude uniformly bounded scalar curvature for all positive times by local parabolic estimates (see Proposition 3.6). Then we use the monotonicity of certain integral norms of scalar curvature along with Moser iteration to first show that \(\|R\|_{L^\infty} \rightarrow 0\) as \(t \rightarrow \infty\).

**Proposition 1.6.** Along the Yamabe flow \((M^n, g(t))\) starting from a \(C^{k+\alpha-\tau}_k\) AF manifold with \(Y(M, [g_0]) > 0\), \(k \geq 3\), and \(\tau > 0\), we have that

\[
\sup_{x \in M^n} |R(x,T)| \xrightarrow{T \to \infty} 0.
\]

After this we obtain a quantitative decay rate estimate of the \(L^\infty\)-norm of \(R_{g(t)}\) along the flow. This gives rise to the following result, which is an important step towards deriving our desired convergence of the flow.

**Proposition 1.7.** Let \((M^n, g_0)\) be a \(C^{k+\alpha}_k\) AF manifold with \(Y(M, [g_0]) > 0\), \(k \geq 3\), and \(\tau > 0\). Then for any \(\delta < \frac{\tau}{2}\) there exists \(C > 0\) such that \(\|R\|_{L^\infty} \leq Ct^{-1-\delta}\).

This decay rate estimate will allow us to derive our first uniform convergence result, Theorem 1.2. In fact, it will also be strong enough to allow us to conclude our first weighted convergence result, Theorem 1.3 once we further assume on the order of asymptotic flatness that \(\tau > 1\). However, as mentioned before this condition is too restrictive when \(n = 3\) because it excludes many manifolds with well-defined mass. So in this case we need another estimate which gives faster decay of the scalar curvature than in Proposition 1.7. By adding the natural conditions of nonnegative, integrable scalar curvature, we can satisfactorily weaken the restriction on \(\tau\). Although analogues of the following estimate can be proven for other dimensions as well, we will only state it for dimension \(n = 3\) since Proposition 1.7 already sufficiently covers dimensions \(n \geq 4\).

**Proposition 1.8.** In the setting of Proposition 1.7 if \(n = 3\), \(\tau > \frac{1}{2}\), \(R_{g_0} \geq 0\), and \(R_{g_0} \in L^1(M^n, g_0)\), then for all \(\alpha < \frac{1}{2}\) there exists \(C > 0\) such that \(\|R\|_{L^\infty} \leq Ct^{-\alpha}\).

Together, Propositions 1.7 and 1.8 allow us to establish that \(u(t)\) must converge to some \(u_\infty\) which is asymptotic to 1 and is a conformal factor corresponding to a scalar flat deformation of \(g_0\). We can then conclude that \(u_\infty\) must be the conformal factor corresponding to the unique \(C^{k+\alpha}_k\) scalar flat metric in the conformal class of \(g_0\), and proceed to prove the weighted convergence results of Theorems 1.3 and 1.4.
1.3 Organization of the article

The organization of the article is as follows: In Section 2 we start by recalling some preliminaries on the short time existence of Yamabe flow on AF manifolds as well as definitions of the relevant weighted Hölder spaces and Sobolev spaces, before proceeding in Section 3 to prove the bounds on the conformal factors $u(x,t)$ needed in the rest of the paper. These bounds then allow us to prove the general long-time existence result, Theorem 1.1, as well as the uniform scalar curvature estimate of Proposition 3.6 when $Y(M^n,[g_0]) > 0$. In Section 4 we study the decay of the scalar curvature under the flow when $Y(M,[g_0]) > 0$ in order to prove Propositions 1.7 and 1.8. In Section 5 we use these estimates to first prove uniform convergence in Theorem 1.2, and then our weighted convergence results of Theorems 1.3 and 1.4.

2 Preliminaries

We begin with a brief general discussion of Yamabe flow, before proceeding to introduce background results on the short-time existence of Yamabe flow on asymptotically flat manifolds and conformal deformations.

Suppose that $(M^n,g(t))$ evolves according to the Yamabe flow with initial metric $g_0$, satisfying

$$\begin{align*}
\frac{\partial}{\partial t} g &= -R_g, \\
g(0) &= g_0.
\end{align*}$$

Since $g(t)$ remains in the same conformal class along the flow, we may write $g(t) = u(t)^{-4/n}g_0$. Then we have the following relation between $R_g$ and $R_{g_0}$:

$$-a(n)\Delta_{g_0}u + R_{g_0}u = R_gu^{\frac{n+2}{n-2}},$$

where $a(n) = \frac{4(n-1)}{n-2}$. Thus the Yamabe flow can be rewritten as an evolution equation for the conformal factor $u(t)$:

$$\frac{\partial}{\partial t}u^{\frac{n+2}{n-2}} = \frac{n+2}{4} \left(a(n)\Delta_{g_0}u - R_{g_0}u\right).$$

Below, we will often denote $N = \frac{n+2}{n-2}$.

2.1 Analytic preliminaries

We first recall some standard function spaces and related definitions used in the analysis and definition of asymptotically flat (AF) manifolds. See for instance [Bar86; DM18].

**Definition 2.1.** Let $M^n$ be a complete differentiable manifold such that there exists a compact $K \subset M^n$ and a diffeomorphism $\Phi : M^n \setminus K \to \mathbb{R}^n \setminus B_{R_0}(0)$, for some $R_0 > 0$. Let $r \geq 1$ be a smooth function on $M^n$ that agrees under...
the identification $\Phi$ with the Euclidean radial coordinate $|x|$ in a neighborhood
of infinity, and let $\hat{g}$ be a smooth metric on $M^n$ which is equal to the Euclidean
metric in a neighborhood of infinity under the identification $\Phi$. Then with all
quantities below computed with respect to the metric $\hat{g}$, we have the following
function spaces:

The weighted Lebesgue spaces $L^q_\beta(M)$, for $q \geq 1$ and weight $\beta \in \mathbb{R}$, consist of
those locally integrable functions on $M$ such that the following respective norms
are finite:

$$\|v\|_{L^q_\beta(M)} = \begin{cases} \left( \int_M |v|^{q\beta-q-n} \, dx \right)^{\frac{1}{q}}, & q < \infty, \\ \text{ess sup}_M (r^{-\beta}|v|), & q = \infty. \end{cases}$$

The weighted Sobolev spaces $W^{k,q}_\beta(M)$ are then defined in the usual way with
the norms

$$\|v\|_{W^{k,q}_\beta(M)} = \sum_{j=0}^k \|D^j v\|_{L^q_{\beta-j}(M)}.$$ 

The weighted $C^k$ spaces $C^k_\beta(M)$ consist of the $C^k$ functions for which the
following respective norms are finite:

$$\|v\|_{C^k_\beta(M)} = \sum_{j=0}^k \sup_{x \in M} r^{-\beta+j} |D^j v|.$$ 

The weighted Hölder spaces $C^{k+\alpha}_\beta(M)$, $\alpha \in (0,1)$, consist of those $v \in C^k_\beta(M)$ for which the following respective norms are finite:

$$\|v\|_{C^{k+\alpha}_\beta(M)} = \|v\|_{C^k_\beta(M)} + \sup_{x \neq y \in M} \min(r(x),r(y))^{-\beta+k+\alpha} \frac{|D^k v(x) - D^k v(y)|}{d(x,y)^\alpha}.$$ 

Remark. The function spaces defined above are independent of the choices of
$\hat{g}$ and $r$. In fact, different choices of the metric $\hat{g}$ and the positive function $r$
will produce equivalent norms. Since $\hat{g}$ agrees with the Euclidean metric in a
neighborhood of infinity, we will often use $\delta_{ij}$ to denote a choice of metric $\hat{g}$.

We can now define our precise notions of asymptotically flat metrics. An
asymptotically flat manifold is then a smooth manifold with an asymptotically
flat metric.

**Definition 2.2 (Asymptotically flat metrics).** Given $M^n$ as in Definition 2.1,
a metric $g$ is said to be a $W^{k,q}_{-\tau}$ (respectively $C^k_{-\tau}$, $C^{k+\alpha}_{-\tau}$) asymptotically flat (AF) metric if $\tau > 0$ and

$$g - \hat{g} \in W^{k,q}_{-\tau}(M) \quad \text{(respectively $C^k_{-\tau}(M)$, $C^{k+\alpha}_{-\tau}(M)$).} \quad \text{(2.4)}$$

The number $\tau > 0$ is called the order of the asymptotically flat metric.
2.2 Short-time existence

We now recall the short-time existence results for Yamabe flow on asymptotically flat manifolds which will be used in this paper. The short-time existence of the Yamabe flow starting from an asymptotically flat manifold and the preservation of asymptotic flatness along the flow have been established by Cheng–Zhu for $C^{2+\alpha}_{-\tau}$ AF metrics (quoted in Theorem 2.6 below). However, we will study certain higher order $C^{k+\alpha}_{-\tau}$ AF metrics along the Yamabe flow; hence we will also check that results analogous to those of Cheng–Zhu hold in these cases as well.

We start by recalling the definition of the particular kind of solution of the Yamabe flow which we will consider throughout. As mentioned earlier, whether the Yamabe flows defined below are unique in general remains open.

**Definition 2.3 (CZ15, Definition 1.2)**. We say that $g(t)$ is a fine solution of the Yamabe flow on a complete manifold $(M^n, g_0)$ on a maximal time interval $[0, T_0)$ if $g(t) = u(t)^{\frac{2}{n-2}}g_0$ with $u(0) \equiv 1$ satisfies \(1.1\) and for any $T \in (0, T_0)$ there exists $\delta = \delta(T)$ and $C = C(T)$ such that on $[0, T]$, $0 < \delta \leq |u(x, t)| \leq C$, $\sup_{[0, T] \times M^n} |\nabla u, u(x, t)| \leq C$, $\sup_{[0, T] \times M^n} |Rm(g)|(x, t) \leq C$, and moreover either $T_0 < \infty$ and $\lim_{t \to T_0} \|Rm\| = \infty$, or $T_0 = \infty$.

**Remark.** In fact by MCZ15, Theorem 1, the blowup alternative in the definition above also holds true when rewritten in terms of the scalar curvature: we must have either $T_0 < \infty$ and $\lim_{t \to T_0} |Rm(\cdot, t)| = \infty$ or $T_0 = \infty$.

We now quote Cheng–Zhu’s results on the existence of fine solutions to the Yamabe flow starting from $C^{2+\alpha}_{-\tau}$ AF manifolds.

**Theorem 2.4 (CZ15, Corollary 2.5).** If $(M^n, g_0)$ is a $C^{2+\alpha}_{-\tau}$ AF manifold, $\tau > 0$, then there exists a fine solution of the Yamabe flow starting from $(M^n, g_0)$ on a maximal time interval $[0, T_0)$ with $T_0 > 0$.

**Theorem 2.5 (CZ15, Theorem 1.3).** Let $u(x, t)$ on $0 \leq t < T_0$ be the conformal factor corresponding to a fine solution to the Yamabe flow on a $C^{2+\alpha}_{-\tau}$ AF manifold $(M^n, g_0)$ with $u(\cdot, 0) \equiv 1$, and let $v = 1 - u$. Then $v(x, t) \in C^{2+\alpha}_{-\tau}(M)$. Hence $g_{ij}(t) - \delta_{ij} \in C^{2+\alpha}_{-\tau}(M)$ for $t \in [0, T_0)$, and in particular $(M^n, g(t))$ remains a $C^{2+\alpha}_{-\tau}$ AF manifold along the Yamabe flow for $t \in [0, T_0)$.

As mentioned before, we require the analogues of the above two results for AF manifolds with estimates also on higher order derivatives — in particular, for $C^{k+\alpha}_{-\tau}$ AF manifolds, $k \geq 2$. Clearly if we replace $C^{2+\alpha}_{-\tau}$ with $C^{k+\alpha}_{-\tau}$ in the statement of Theorem 2.4 the statement remains true. Thus we can conclude with the analogue of Theorem 2.5 below. The proof is a straightforward adaptation of Cheng–Zhu’s proof of Theorem 2.5 and is presented in Appendix A.

**Theorem 2.6.** Let $u(x, t)$ on $0 \leq t < T_0$ be the conformal factor corresponding to a fine solution to the Yamabe flow on a $C^{k+\alpha}_{-\tau}$ AF manifold $(M^n, g_0)$, $k \geq 2$, with $u(\cdot, 0) \equiv 1$, and let $v = 1 - u$. Then $v(x, t) \in C^{k+\alpha}_{-\tau}(M)$. Hence $g_{ij}(t) - \delta_{ij} \in C^{k+\alpha}_{-\tau}(M)$ for $t \in [0, T_0)$, and in particular $(M^n, g(t))$ remains a $C^{k+\alpha}_{-\tau}$ AF manifold along the Yamabe flow for $t \in [0, T_0)$.
3 Bounds on the conformal factor and long-time existence

In this section we recall the results of [CB81; DM18] on conformal deformations of asymptotically flat metrics in order to obtain upper and lower bounds on the conformal factor \( u(t) \) as it evolves along Yamabe flow. These bounds will then imply the long-time existence of any fine Yamabe flow starting from an asymptotically flat manifold.

3.1 Conformal deformations of asymptotically flat metrics

Observe that if \( \tilde{g}_0 = v^{\frac{4}{n-2}} g_0 \) is a fixed metric conformal to the initial metric \( g_0 \) on \( M^n \) from which we start a Yamabe flow, then the conformal factor \( u(t) \) of (2.3) also satisfies for \( w = u(t) v^{-1} \),

\[
\frac{\partial}{\partial t} w^{\frac{n+2}{4}} = \frac{n+2}{4} \left( a(n) \Delta \tilde{g}_0 w - R_{\tilde{g}_0} w \right),
\]

which is exactly (2.3) but with \( \tilde{g}_0 \) and \( w(t) \) replacing \( g_0 \) and \( u(t) \), respectively.

This suggests making an advantageous choice of background metric \( \tilde{g}_0 \) with which to study (3.1). First, Dilts–Maxwell showed that for suitable \( W^{k,p} \) AF manifolds, it is always possible to deform to negative scalar curvature [DM18]. For our purposes it is more convenient to work with \( C^{k+\alpha} \) AF manifolds, and the analogous statement holds in this setting as well.

**Proposition 3.1.** Let \( (M^n, g) \) be a \( C^{k+\alpha} \) AF manifold, \( k \geq 2 \) with \( \tau \in (0, n-2) \). Suppose \( R' \in C^{k+\alpha}_{-\tau} \) satisfies \( R' \leq R_g \). Then there exists a positive function \( \phi \) with \( \phi - 1 \in C^{k+\alpha}_{-\tau} \) such that the scalar curvature of \( g' = \phi^{\frac{n+2}{4}} g \) is \( R' \). In particular \( g' \) is also a \( C^{k+\alpha}_{-\tau} \) AF metric.

If instead we want to conformally deform to \( R' \equiv 0 \), then work of Cantor–Brill [CB81] (corrected and completed by Maxwell [Max05]) tells us that we can do so for AF metrics belonging to suitable \( W^{k,p} \) classes if and only if they are Yamabe positive [CB81; Max05]. Again, the analogous statement holds for \( C^{k+\alpha}_{-\tau} \) AF manifolds.

**Proposition 3.2.** Let \( (M^n, g) \) be a \( C^{k+\alpha}_{-\tau} \) AF manifold, \( k \geq 2 \), with \( \tau \in (0, n-2) \). Then the following are equivalent:

1. We have \( Y(M, [g]) > 0 \).
2. There exists a positive function \( \phi \) with \( \phi - 1 \in C^{k+\alpha}_{-\tau} \) such that \( \tilde{g} = \phi^{\frac{1}{n+2}} g \) is conformally equivalent to \( \tilde{g} \) and \( R_{\tilde{g}} \equiv 0 \).

We will describe how Propositions 3.1 and 3.2 follow from their \( W^{k,p} \) versions in Appendix B.
3.2 Conformal factor bounds

By making a suitable choice of background metric as detailed earlier, with the results of Section 3.1 we can obtain some control of the conformal factor $u(t)$ of (2.3) along the Yamabe flow of an asymptotically flat metric. In turn we can then achieve some control of the Sobolev constant as defined below.

**Definition 3.3.** If $(M^n, g)$ is a $C^0$−$\tau$ AF manifold, then there exists a smallest constant $C_g > 0$ such that for every $u \in W^{1,2}(M, g)$, the following $L^2$ Euclidean-type Sobolev inequality holds:

$$\left( \int \frac{|u|^{2n}}{n^n} \, dV_g \right)^{\frac{n-2}{4n-4}} \leq C_g \int |\nabla u|^2 \, dV_g.$$  

(3.2)

We call $C_g$ the Sobolev constant of the metric $g$.

**Remark.** It is well known that $C_{n,e} \leq C_g$, where $C_{n,e}$ is the Sobolev constant of the flat metric on $\mathbb{R}^n$; see for instance [Heb99, Proposition 4.2].

We will consider two cases — first, the general case where $(M^n, g_0)$ is an arbitrary $C^{k+\alpha}$−$\tau$ AF manifold, and second, the case when moreover $Y(M^n, [g_0]) > 0$. In the general case, below we show that for any finite time $T > 0$, the conformal factor $u(t)$ is bounded away from both 0 and $\infty$.

**Lemma 3.4.** If $u(x,t)$ is a solution of (2.3) corresponding to a fine solution of the Yamabe flow starting from the $C^{k+\alpha}$−$\tau$ AF manifold $(M^n, g_0)$, $k \geq 2$, then for any $T$ for which the Yamabe flow exists on $[0, T]$, there exists a $C(T) > 0$ depending only on $T$ and $g_0$ such that we have the bounds

$$0 < C(T)^{-1} \leq u(x; t) \leq C(T) < \infty,$$

(3.3)

for any $(x, t) \in [0, T] \times M$.

**Proof.** First, observe that

$$\frac{\partial}{\partial t} u = -\frac{n-2}{4} R_g(t) u \leq -\frac{n-2}{4} \left( \inf_{x \in M} R_{g(0)}(x) \right) u,$$

since $\inf_{x \in M} R_{g(t)}(x)$ is nondecreasing under the Yamabe flow. Therefore we have $u(x, t) \leq C(T) < \infty$ if the flow exists on $[0, T]$ for $C(T) > 0$ depending only on $T$ and $\inf_{x \in M} R_{g(0)}(x)$.

Next, using Proposition 3.1 we may write $w = u(t) v^{-1}$ as in (3.1), with $v$ corresponding to a suitable choice of prescribed $R_{g_0} < 0$ with rapid decay. The following maximum principle type argument shall give us the lower bound on $u$, and hence $w$ also, thereby completing the proof.

Let $U \subset M$ be an open set, and let $U_{t_0} = (0, t_0] \times U$, $\Gamma_{t_0} = (\{0\} \times U) \cup ([0, t_0] \times \partial U)$. We claim that for $\epsilon > 0$, if the Yamabe flow exists on $[0, t_0]$,
then the minimum of \( w + \epsilon t \) cannot be achieved on \( U_{t_0} \). Otherwise, at such a space-time point \((x,t)\) in \( U_{t_0}\), we have \( \frac{\partial}{\partial t} (w + \epsilon t) \leq 0 \), and

\[
0 \geq \frac{\partial}{\partial t} (w + \epsilon t) = w^{1-N} \left( \frac{n-2}{4} \right) (a(n) \Delta g_0 (w + \epsilon t) - R_{g_0} w) + \epsilon > w^{1-N} \left( \frac{n-2}{4} \right) a(n) \Delta g_0 (w + \epsilon t).
\]

But this is impossible, since \( \Delta g_0 (w + \epsilon t) \geq 0 \) at the point we consider, so we have proven the claim. This implies \( w(x,t) \geq \inf_{x \in M} w(x,0) > 0 \), giving us the desired lower bound.

Indeed, suppose at some \((x,t)\) that \( w(x,t) < \inf_{x \in M} w(x,0) \); then if we take \( \epsilon > 0 \) sufficiently small we also have \( w(x,t) + \epsilon < \inf_{x \in M} w(x,0) \) at this same space-time point. But \( w \) is asymptotic to 1 at spatial infinity in the interval \([0,t_0]\), so by taking \( U \) sufficiently large we see that this means \( w + \epsilon t \) achieves a minimum in \( U_t \), which we have seen is impossible.

Lemma 3.4 immediately implies the long-time existence of the Yamabe flow under the hypotheses of Theorem 1.1.

**Proof of Theorem 1.1.** Suppose on the contrary that \((M^n, g(t))\) is a fine solution of the Yamabe flow starting from a \( C^{2+\alpha}_r \) AF manifold \((M^n, g_0)\) which exists up to a finite-time singularity \( T > 0 \). But Lemma 3.4 implies that the conformal factor \( u(t) \) is uniformly bounded on \([0,T]\), and by estimating as in the proof of Lemma 5.2 it follows by standard parabolic regularity theory that \( u(t) \) is uniformly bounded in \( C^{2+\alpha}_0 \). Hence the scalar curvature of \((M^n, g(t))\) is uniformly bounded on \([0,T]\), contradicting the blowup alternative for fine solutions of the Yamabe flow given in the remark following Definition 2.3.

If we additionally suppose that \( Y(M^n, [g_0]) > 0 \), then we can uniformly bound the conformal factor \( u(t) \) both from above and from below.

**Lemma 3.5.** Let \( u(x,t) \) be the solution of (2.3) given by Theorems 2.4 and 2.6 starting from the \( C^{k+\alpha}_r \) AF manifold \((M^n, g_0)\), \( k \geq 2 \), and further suppose that \( Y(M^n, [g_0]) > 0 \). Then for any time interval \([0,T]\) on which \( u \) is defined and any \((x,t) \in [0,T] \times M\), there exist \( C_1, C_2 > 0 \) depending only on \( g_0 \) such that

\[
0 < C_1 \leq u(x,t) \leq C_2 < \infty.
\]

**Proof.** We already saw in the proof of Lemma 3.4 how to obtain the lower bound \( 0 < C_1 \leq u(x,t) \), so we only need to justify the upper bound.

Write \( w = u(t)^{-1} \) as in (3.1), with \( v \) given by the conformal factor corresponding to \( R_{g_0} \equiv 0 \) whose existence is given by Proposition 3.2. Using the same notation as in the proof of Lemma 3.4, we claim that for \( \epsilon > 0 \), the maximum of \( w - \epsilon t \) cannot be achieved on \( U_{t_0} \). Otherwise, at such a point in \( U_{t_0} \),
we have \(\frac{\partial}{\partial t}(w - ct) \geq 0\), and therefore
\[
0 \leq \frac{\partial}{\partial t}(w - ct) = w^{1-N} \left( \frac{n-2}{4} \right) a(n) \Delta_{g_0}(w - ct) - \epsilon
\]< \[w^{1-N} \left( \frac{n-2}{4} \right) a(n) \Delta_{g_0}(w - ct) - \epsilon.
\]

But \(\Delta(w - ct) \leq 0\) at such a maximum point, giving a contradiction, thus proving the claim.

This implies the upper bound. For if instead there exists \((x, t)\) such that \(w(x, t) > \sup_{y \in M} w(0, y)\), then \(u(x, t) - ct > \sup_{y \in \mathbb{R}^n} u(0, y)\) for \(\epsilon > 0\) sufficiently small. Since \(u\) is asymptotic to 1 at spatial infinity, if we take \(U\) sufficiently large, then \(u - ct\) achieves a maximum in \(U_t\), which we have seen is impossible. \(\square\)

Lemma 3.5 then implies the uniform boundedness of the scalar curvature for all positive times by the same argument used to prove Theorem 1.1. We will need this fact later.

**Proposition 3.6.** Let \((M^n, g_0)\) be a \(C^{k+\alpha}_{-\tau}\) AF manifold with \(Y(M, [g_0]) > 0\), \(k \geq 3\), and \(\tau > 0\). Then the Yamabe flow starting from \((M^n, g_0)\) has scalar curvature uniformly bounded in time for all \(t > 0\).

**Proof.** Because of the uniform bounds from Lemma 3.5, standard parabolic regularity theory applied to the evolution equation of \(u(t)\) implies that the scalar curvature \(R\) is uniformly bounded for all \(t > 0\). \(\square\)

Moreover, as a consequence of Lemma 3.5 for the Yamabe flow starting from an asymptotically flat manifold with \(Y(M^n, [g_0]) > 0\) we have uniform control of the Sobolev constant of \((M^n, g(t))\) for all positive times. This will allow us to study the convergence of the flow as \(t \to \infty\).

**Corollary 3.7.** If \(u(x, t)\) is the solution of \((2.3)\) corresponding to a fine solution of the Yamabe flow starting from the \(C^{k+\alpha}_{-\tau}\) AF manifold \((M^n, g_0)\), \(k \geq 2\), and moreover \(Y(M, [g_0]) > 0\), then there exists a constant \(D = D(g_0)\) such that for any \(T\) for which the Yamabe flow exists on \([0, T]\) the following Sobolev inequality holds for every \(u \in W^{1,2}(M, g(t))\):
\[
\left( \int |u|^{\frac{2n}{n-2}} \, dV_{g(t)} \right)^{\frac{n-2}{n}} \leq D \int |\nabla u|^2 \, dV_{g(t)}.
\]

(3.5)

**4 Evolution of the scalar curvature**

We now study the evolution of the scalar curvature \(R\) along the Yamabe flow starting from an asymptotically flat manifold in the case where \(Y(M^n, [g_0]) > 0\) holds, in preparation for proving convergence result of Theorem 1.3. Recall that at this point we already have the general long-time existence by Theorem 1.1 proved in the previous section. Using in this case \(Y(M^n, [g_0]) > 0\) setting the uniform \(L^2\)
Euclidean-type Sobolev inequality for all positive times, we first establish the monotonicity of certain integral norms of $R$, and then proceed to establish the decay rate estimates of Proposition 1.7 and 1.8 on the $L^\infty$ norm of $R$ in time.

4.1 Monotonicity of some integral norms of the scalar curvature

We have the following equations for the evolution of the scalar curvature and the volume form under the Yamabe flow:

$$\frac{\partial}{\partial t} R = (n-1)\Delta R + R^2, \quad \frac{\partial}{\partial t} dV_t = -\frac{n}{2} R \ dV_t$$

Under the hypotheses of Theorem 1.3 we can therefore compute the evolution of $\|R\|_{L^p}$ along the Yamabe flow for $p$ sufficiently large.

Lemma 4.1. Let $(M^n, g_0)$ be a $C^{k+\alpha}_{k+\tau}$ AF manifold with $Y(M, [g_0]) > 0$, $k \geq 3$ and $\tau \in (0, n-2)$. Then for all $p > \frac{n^2}{2+\tau}$, along the Yamabe flow starting from $(M^n, g_0)$ we have

$$d \int |R|^p \ dV_t \leq -\frac{4(n-1)(p-1)}{p} \int |\nabla |R|^\frac{p}{2}|^2 \ dV_t + (p - \frac{n}{2}) \int |R|^p R \ dV_t. \tag{4.1}$$

Proof. This follows from

$$\frac{\partial}{\partial t} R^2 = (n-1)\Delta R^2 - 2(n-1)|\nabla R|^2 + 2R^3,$$

and

$$d \int |R|^p \ dV_t = \int \frac{p}{2}(R^2)^{\frac{p}{2} - 1} \frac{\partial}{\partial t} R^2 - \frac{n}{2} |R|^p R \ dV_t, \tag{4.2}$$

since by our assumptions on the asymptotic decay of $(M^n, g_0)$ which are preserved along the flow by Theorem 2.6 (and indeed for all positive times by Theorem 1.3) these integral quantities are well-defined.

Since $C^{k+\alpha}_{k+\tau}$ AF manifolds are also $C^{k+\alpha}_{k+\tau}$ if $\tau > \bar{\tau}$, for the purposes of proving Theorem 1.3 it suffices to assume that $\tau < n - 2$, in which case we always have $p > \frac{n^2}{2+\tau} > 1$. Therefore we will always be assuming that $\tau < n - 2$ in the rest of this paper. Next we establish that $||R||_p$ is a monotonically nonincreasing quantity along the flow, for appropriate $p$.

Corollary 4.2. We have that $\frac{d}{dt} \int |R|^\frac{p}{2} \ dV_t \leq 0$.

As a result we also have monotonicity of $\frac{d}{dt} \int |R|^p \ dV_t$, for $p$ close to $\frac{n^2}{2}$, as well as the integrability in time of certain other $L^p$ norms of $R$ in space, which will be important when we establish the $L^\infty$ decay of $R$. 

14
Lemma 4.3. There exists $\epsilon = \epsilon(g_0) > 0$ such that $\frac{d}{dt} \int |R|^p \, dV_t \leq 0$ for all $p \in \left( \frac{n}{2} - \epsilon, \frac{n}{2} + \epsilon \right)$. Moreover for all such $p$,

$$\int_0^\infty \left( \int |R|^{p \frac{n}{n-2}} \, dV_t \right)^{\frac{n-2}{n}} \, dt < \infty. \quad (4.3)$$

Proof. Applying the Sobolev inequality (3.5) to the first term and the Hölder inequality to the second term on the right-hand side of (4.1), we obtain

$$\frac{d}{dt} \int |R|^p \, dV_t \leq -\frac{C(n,p)}{D} \left( \int |R|^{p \frac{n}{n-2}} \, dV_t \right)^{\frac{n-2}{n}} + \left| p - \frac{n}{2} \right| \left( \int |R|^{p \frac{n}{n-2}} \, dV_t \right)^{\frac{n-2}{n}} \left( \int |R|^{\frac{n}{2}} \, dV_t \right)^{\frac{2}{n}}. \quad (4.4)$$

Hence there exists an $\epsilon > 0$ such that if $p - \frac{n}{2} < \epsilon$ then

$$-\frac{C(n,p)}{K} + \left| p - \frac{n}{2} \right| \| R_{g_0} \|_{L^\infty} < 0, \quad (4.5)$$

which implies that $\frac{d}{dt} \int |R|^p \, dV_t \leq 0$, since we know that $\frac{d}{dt} \int |R|^p \, dV_t$ is nonincreasing.

For such $p$, we additionally see that (4.4) implies

$$\frac{d}{dt} \int |R|^p \, dV_t + C \left( \int |R|^{p \frac{n}{n-2}} \, dV_t \right)^{\frac{n-2}{n}} \leq 0,$$

for some $C$ which may depend on $n$, $p$, and $g_0$. Since $\int |R|^p \, dV_t$ is nonincreasing and nonnegative, we may integrate this inequality to deduce (4.3).

Remark. In order to prove Proposition 1.7 we actually need the monotonicity in Corollary 4.3 to hold for all $p > \frac{n}{2 + \tau}$ (for sufficiently large times). But to justify this fact we will need to demonstrate the decay of $\| R \|_\infty$ first in Proposition 4.4 below, before returning to this in Corollary 4.6.

In the above discussions, if $p < 2$ (such as when $n$ is small) then one may wish to be careful with the $|\nabla |R|^{\frac{n}{2}}|^2$ integrand in (4.1). We check that the discussion in this section leading up to Lemma 4.3 still holds in this context in Appendix C.

4.2 Uniform decay of $R$

Having obtained the decay of appropriate integral norms of $R$, we can now proceed to control the $L^\infty$ norm of $R$ along the flow by Moser iteration arguments similar to those in [Yan88]. The central ideas are standard, but we include some details for clarity because we need to adapt them to obtain precise control on the decay rate of $R$, similar to the situation for $|R_m|$ on certain asymptotically flat Ricci flows studied by the first named author in [Che19].

In fact we will need to pass from $L^p$ to $L^\infty$ control of $R$ several times, so we begin with the following estimate with somewhat general assumptions.
Proposition 4.4. Let \((M^n, g(t))\) be a Yamabe flow starting from \(C_{k+\alpha}^+\) AF manifold with \(Y(M, [g_0]) > 0\), \(k \geq 3\), and \(\tau \in (0, n - 2)\), and suppose that

\[
\| R \|_{L^q} \leq C \beta t^{-\gamma_1}, \quad \text{for } q > \frac{n}{2},
\]

\[
\| R \|_{L^{p_0}} \leq C \alpha t^{-\gamma_2}, \quad \text{for } p_0 > \frac{n}{2 + \tau},
\]

for some nonnegative constants \(\alpha, \alpha_1, \alpha_2, \gamma_1, \gamma_2\). Then there exists a constant \(C = C(n, q, p_0, \alpha_1, \alpha_2, g_0) > 0\) such that

\[
\sup_{x \in M^n} | R(x, T) | \leq C \max \left\{ T^{-\frac{n-\gamma_1}{p_0(2q-n)} - \gamma_2}, T^{-\frac{n}{2p_0} - \gamma_2} \right\} \cdot \hat{t}. \tag{4.8}
\]

Proof. We selectively denote \( f = |R| \) below in order to distinguish the roles that different factors of \( |R| \) play. Applying Hölder’s inequality to the second term on the right in (4.1), we see that for any \(0 < T < \tau < T\), we obtain for all \( p \geq 0 \), assuming the integrability of all terms involved. We restrict to \( p > \frac{n}{2 + \tau} \) because of the spatial decay of \( f = |R| \) on a \( C_{k+\alpha}^+ \) AF manifold, recalling that we assume \( \tau < n - 2 \). Let \( \beta = \beta(t) = \alpha_1 t^{-\gamma_1} \), so that \( \| R \|_{L^q} \leq \beta(t) \). We apply Young’s inequality to the last term on the right to see that

\[
\frac{1}{p} \frac{d}{dt} \int f^p \, dV_t \leq -4 \frac{(p-1)}{p^2} (n-1) \int | \nabla \hat{t} |^2 \, dV_t
\]

\[
+ \left( \frac{1}{4} \int | R |^q \, dV_t \right)^{1-p} \left( \frac{1}{4} \int f^p \, dV_t \right)^{1-\frac{1}{p}}
\]

\[
= \left( \delta^{1-\frac{n}{p} \tau} \int f^{p \delta^{-\frac{n}{q}}} \, dV_t \int f^{(4)(1-\frac{n}{q})} \, dV_t \right)^{\frac{n-2}{q}}.
\]

Note that the above in fact holds for all \( p > 1 \), assuming the integrability of all terms involved. We restrict to \( p > \frac{n}{2 + \tau} \) because of the spatial decay of \( f = |R| \) on a \( C_{k+\alpha}^+ \) AF manifold, recalling that we assume \( \tau < n - 2 \). Let \( \beta = \beta(t) = \alpha_1 t^{-\gamma_1} \), so that \( \| R \|_{L^q} \leq \beta(t) \). We apply Young’s inequality to the last term on the right to see that

\[
\frac{1}{p} \frac{d}{dt} \int f^p \, dV_t \leq -4 \frac{(p-1)}{p^2} (n-1) \int | \nabla \hat{t} |^2
\]

\[
+ \beta^{\delta^{(1-\frac{n}{p} \tau)}} \int f^p \, dV_t + \beta^{\delta^{(1-\frac{n}{p} \tau)}} \left( \int f^{(4)(1-\frac{n}{q})} \, dV_t \right)^{\frac{n-2}{q}}.
\]

Applying the Sobolev inequality \(3.5\) to the last term on the right above and setting \( \delta = \left( \frac{3(p-1)(n-1)}{\beta D^{p-1}} \right)^{\frac{2q}{n-2q}} \), we obtain for all \( p \geq p_0 \)

\[
\frac{d}{dt} \int f^p \, dV_t + C_{p_0} \int | \nabla \hat{t} |^2 \, dV_t \leq C_{p,q,\beta} \int f^p \, dV_t, \tag{4.9}
\]

where \( C_{p_0} = \frac{(p_0-1)(n-1)}{p_0} \) and \( C_{p,q,\beta} = \beta^{\frac{\beta D}{3p-1}(n-1)} \left( \frac{2q}{n-2q} \right)^{\frac{n-2q}{n}} \). Now define, for \( \frac{\tau}{2} < \tau < \tau' < T \), the function \( \psi : [0, T] \rightarrow [0, 1] \),

\[
\psi(t) = \begin{cases} 0, & 0 \leq t \leq \tau, \\ \frac{t-\tau}{\tau'-\tau}, & \tau \leq t \leq \tau', \\ 1, & \tau' \leq t \leq T. \end{cases}
\]

16
Then we multiply (4.9) by \( \psi \) and find that

\[
\frac{d}{dt} \left( \psi \int f^p \, dV_t \right) + \psi C_{p_0} \int |\nabla (f^p \psi)|^2 \, dV_t \leq \left( C_{p,q,\beta} + \frac{1}{\tau' - \tau} \right) \int f^p \, dV_t,
\]

so that integrating and using the fact that \( \beta(t) \) is decreasing, for any \( \tilde{t} \in [\tau', T] \) we have

\[
\int_{\tau'}^{\tilde{t}} f^p \, dV_t + C_{p_0} \int_{\tau'}^{\tilde{t}} |\nabla (f^p \psi^2)|^2 \, dV_t \, dt \leq \left( C_{p,q,\beta(\tau)} + \frac{1}{\tau' - \tau} \right) \int_{\tau}^{\tilde{t}} \int f^p \, dV_t \, dt.
\]

(4.10)

We now define for \( \tau \in [0, T] \),

\[
H(p, \tau) = \int_{\tau}^{T} \int f^p \, dV_t \, dt,
\]

and let \( \nu = 1 + \frac{2}{n} \). We claim that for \( p > \frac{n + \tau}{2} \) and \( 0 \leq \tau < \tau' \leq T \),

\[
H(\nu p, \tau') \leq \left( D C_{p_0} \right) \frac{\nu}{\nu p_k} \frac{\nu}{\nu p_k} H(p, \tau)^{\nu}. \tag{4.11}
\]

Indeed,

\[
\int_{\tau'}^{T} \int f^{\nu p} \, dV_t \, dt \leq \int_{\tau'}^{T} \left( \int f^p \, dV_t \right)^{\frac{n}{\nu}} \left( \int f^{\frac{2n}{2n - n}} \, dV_t \right)^{\frac{2n - 2}{n}} \, dt
\]

\[
\leq D \left( \sup_{\tau' \leq \xi \leq T} \int f^p \, dV_t \right)^{\frac{n}{2}} \int_{\tau'}^{T} \int |\nabla (f^p \psi)|^2 \, dV_t \, dt,
\]

so that (4.10) implies the claim. Now we iterate (4.11) to obtain \( L^\infty \) control.

Let \( p_0 \) be as assumed in (4.7), and define

\[
\eta = \nu \frac{2n}{2n - n}, \quad p_k = \nu^k p_0, \quad \tau_k = \frac{T}{2} + \left( 1 - \eta^{-k} \right) \frac{T}{2}, \quad \Phi_k = H(p_k, \tau_k)^{\frac{1}{p_k}}. \tag{4.12}
\]

We apply (4.11) to see that

\[
\Phi_{k+1} = H(\nu p_k, \tau_{k+1})^{\frac{1}{p_k}} \leq \left( D C_{p_0} \right) \frac{1}{p_k} \left( C_{p_k,q,\beta(\tau_k)} + \frac{1}{\tau_{k+1} - \tau_k} \right) \frac{1}{p_k} H(p_k, \tau_k)^{\frac{1}{p_k}}
\]

\[
\leq \left( D C_{p_0} \right) \frac{1}{p_k} \left( C_1(n, q, p_0) D^{\frac{n}{2n - n}} \beta(\tau_k) \frac{2n}{2n - n} + C_2(n, q) \frac{\eta}{T} \right)^{\frac{1}{p_k}} \frac{\eta}{\eta^{p_k}} \Phi_k
\]

\[
\leq \left( D C_{p_0} \right) \frac{1}{p_k} \left( C_1(n, q, p_0) D^{\frac{n}{2n - n}} \left( \frac{\alpha_1}{2} \right)^{\frac{2n}{2n - n}} T^{-\gamma_1} \frac{2n}{2n - n} + C_2(n, q) \frac{\eta}{T} \right)^{\frac{1}{p_k}} \frac{\eta}{\eta^{p_k}} \Phi_k,
\]

where \( \gamma_1 \) is given by (4.10). (4.13)
where 
\[ C_1(n, q, p_0) = \frac{2^{a}}{p_0^{(n-q)/(n-p_0)}} \left( \frac{p_0}{4(p_0-1)(n-1)} \right)^{\frac{n-q}{n-p_0}} \]  
and 
\[ C_2(n, q) = \frac{2}{q-1}. \]
Since 
\[ \sum_{k=0}^{\infty} \frac{1}{p_k} = \frac{1}{p_0} \frac{n+2}{n-q} < \infty \]  
and 
\[ \sum_{k=0}^{\infty} \frac{1}{p_k} < \infty, \]
we can iterate (4.13) to obtain
\[ \sup_{x \in M^n} |R(x, T)| \leq C(n, q, p_0, \alpha_1, D) \max(T^{-\gamma_1}, T^{-1}) \frac{1}{p_0} \frac{n+2}{n-q} \Phi_0. \]  \hspace{1cm} (4.14)

Finally, we have that
\[ \Phi_0 = \left( \int_{\frac{T}{n}}^{T} \int |R|^{p_0} dV_t \ dt \right)^{\frac{1}{p_0}} \leq C(\alpha_2) T^{-\gamma_2}. \]

Putting things together we obtain the claimed estimate for $|R|$. \hfill \Box

Next, by slightly modifying the proof of Proposition 4.4 we will establish Proposition 1.6 which shows that $\|R\|_{L^\infty}$ decays to zero in time.

**Proof of Proposition 1.6** Substituting $p = \frac{n}{2}$ into (4.3) from Lemma 4.3 we have
\[ \int_{0}^{\infty} \left( \int |R|^\frac{n}{2} dV_t \right)^{\frac{n-2}{n}} dt < \infty. \]  \hspace{1cm} (4.15)

Moreover, \[ \int |R|^\frac{n}{2} dV_t \] is uniformly bounded along the flow, since $\|R\|_{L^\infty}$ and $\|R\|_{L^\frac{n}{2}}$ are both uniformly bounded by Proposition 3.6 and Corollary 4.2 respectively. Hence
\[ \int_{0}^{\infty} \int |R|^\frac{n}{2} dV_t < \infty. \]  \hspace{1cm} (4.16)

We now refer back to the proof of Proposition 4.4. Choose $q > \frac{n}{2}$ so that $\|R\|_{L^q} \leq \alpha_1$ for some constant $\alpha_1 = \alpha_1(g_0)$, which is possible by Lemma 4.3 and set $p_0 = \frac{2(n-q)}{n-2}$. Following the same steps up to (4.14) we obtain, with $\gamma_1 = 0$, that
\[ \sup_{x \in M^n} |R(x, T)| \leq C(n, q, \alpha_1, D) \max(1, T^{-\gamma_1}, T^{-1}) \frac{1}{p_0} \frac{n+2}{n-q} \Phi_0. \]

Then, since
\[ \Phi_0 = \left( \int_{\frac{T}{n}}^{T} \int |R|^{p_0} dV_t \ dt \right)^{\frac{1}{p_0}} \xrightarrow{T \to \infty} 0, \]
we find that indeed $\|R\|_{L^\infty} \to 0$ in time. \hfill \Box

Since by Lemma 4.3 $\|R\|_{L^p}$ is uniformly bounded along the flow for $p$ close to $\frac{n}{2}$, Proposition 1.6 allows us interpolate to obtain decay of integral norms of $R$ as well.
Corollary 4.5. For \( \epsilon = \epsilon(g_0) > 0 \) as in Lemma 4.3 and \( p > \frac{n}{2} - \epsilon \), we have \( \|R\|_{L^p} \xrightarrow{t \to \infty} 0 \).

In particular, we have \( \|R\|_{L^\frac{n}{p}} \xrightarrow{t \to \infty} 0 \). This allows us to strengthen the range of exponents covered by Lemma 4.3.

Corollary 4.6. For any \( p > \frac{n}{2} - \epsilon \), we have \( \frac{d}{dt} \int |R|^p \, dV_i \leq 0 \) for \( t \geq T(p) \) sufficiently large. Moreover for all such \( p \),

\[
\left( \int |R|^p \, dV_i \right)^\frac{n-2}{n} = o(t^{-1}).
\] (4.17)

Proof. In the proof of Lemma 4.3 observe that for any fixed \( p \), the inequality (4.3) will hold when \( \|R_r^n\|_{L^\frac{n}{p}} \) is replaced by \( \|R_t^n(t)\|_{L^\frac{n}{p}} \) for all \( t \) sufficiently large, since we now know that \( \|R\|_{L^p} \) decays to zero in time. And because we now know that \( \int |R|^p \, dV_i \) is monotonically nonincreasing in time for \( t \) sufficiently large, the integrability expressed in (4.2) implies (4.17).

We will use these consequences of Proposition 1.6 to strengthen our control of \( R \) and obtain our decay rate estimates on \( \|R\|_\infty \).

### 4.3 Decay rate of \( R \)

Although Proposition 1.6 only told us that \( \|R\|_\infty \) tends to zero, we can use the consequent improved integral decay estimates of Corollary 4.5 and 4.6 to show that the \( L^\infty \) norm of \( R \) must in fact decay at a particular rate, thus proving Proposition 1.7.

Proof of Proposition 1.7. By Corollary 4.6 we have that for any \( p > \frac{n}{2} - \epsilon \) and \( \alpha > 0 \), for sufficiently large times it holds that \( \|R\|_{L^\frac{n}{p(\alpha)}} \leq \alpha^{-\frac{1}{p}} \). Choose \( p_1, p_2 > \frac{n}{2} - \epsilon \) with \( p_1 \frac{n-2}{n-2} > \frac{p_2}{p_2-\alpha} \), and apply the estimate (4.8) of Proposition 4.4 with \( q = p_1 \frac{n}{n-2} \) and \( p_0 = p_2 \frac{n}{n-2} \). We thus obtain the estimate (for \( T \) sufficiently large),

\[
\sup_{x \in M} |R(x, T)| \leq C(n, q, p_0, \alpha_1, \alpha_2, g_0) \max\left\{ T^{-\frac{n^2+4q}{np_2(n-2q)}}, T^{\frac{n-2q}{2p_2}} \right\}. \quad (4.18)
\]

We now compare the two \( T \) exponents above to see that we can achieve the decay exponent in the statement of the Proposition. For the second exponent, clearly as \( p_2 \) approaches \( \frac{n}{2} - \epsilon \) from above the exponent \( -\frac{n^2}{np_2(n-2q)} \) approaches \(-1 - \frac{\epsilon}{2}\) from above. For the first exponent, notice that for fixed \( p_2 > 0 \) we have

\[
\lim_{q \to \frac{4}{n-2}+} \frac{n^2+4q}{np_2(n-2q)} = -\infty. \quad \text{If } \tau \geq \frac{4}{n-2} \text{ then } \frac{n}{2} \geq \frac{n}{n-2} \cdot \frac{n^2+4q}{np_2(n-2q)}, \quad \text{so we will always be able to choose } q > \frac{\tau}{2} \text{ sufficiently close to } \frac{n}{2} \text{ such that } \frac{n^2+4q}{np_2(n-2q)} < -\frac{n}{2p_2}.
\]

On the other hand, if \( 0 < \tau < \frac{4}{n-2} \) then the following inequality holds at \( q_0 = \frac{n}{2} \frac{4}{2p_2(n-2q_0) < \frac{n}{2p_2} .
\]

\[
\frac{n^2+4q_0}{np_2(n-2q_0)} < -\frac{n}{2p_2}.
\]
Hence this inequality remains true if we replace $q_0$ with a $q$ slightly larger than $q_0$, finishing the proof.

As described in the Introduction, the decay in Proposition 1.7 is not quite good enough for our purposes when $n = 3$, so we need the improved estimate of Proposition 1.8 for dimension $n = 3$ under additional assumptions of nonnegative, integrable scalar curvature. We conclude this section with its proof.

**Proof of Proposition 1.8.** By [CZ15, Theorem 1.5], under the assumptions of Proposition 1.8, the scalar curvature remains integrable along the flow and moreover
\[
\frac{d}{dt} \int R \, dV_t \leq -\frac{1}{2} \int R^2 \, dV_t \leq 0.
\]
So we may interpolate with the $L^\infty$ estimate of Proposition 1.7 to find that $\|R\|_p < \infty$ for all $p \geq 1$, and moreover
\[
\|R\|_p = O\left(t^{(-1+\delta)(1-\frac{1}{p})}\right), \tag{4.19}
\]
for all $\delta < \frac{1}{2}$. By our hypothesis on $\tau$ then the evolution equation for $\frac{d}{dt} \int R^p \, dV_t$ is well-defined whenever $p > 1$, so we can apply the estimate (4.8) of Proposition 4.4 with $q = \frac{p}{n-2} = 3p$ and $p_0 = p$, for some $p_1 > \frac{3}{2+\tau}$ and $p > 1$ to be determined. Plugging in $\|R\|_q \leq \alpha_1 t^{-\frac{1}{2}}$ and (4.19) to estimate $\|R\|_{p_0}$, we obtain
\[
\sup_{x \in M^n} |R(x,T)| 
\leq C(n, q, p, \alpha_1, 1, g_0) \max\left\{T^{-\frac{n(q+2)}{n+q(2q-n)}}(1+\delta)(1-\frac{1}{p_1}), T^{-\frac{n}{2q-n}-(1+\delta)(1-\frac{1}{p_1})}\right\}, \tag{4.20}
\]
It suffices to show that given any $\alpha < \frac{3}{2}$ we can choose $q, p_0$ so that both exponents of $T$ are less than $-\alpha$. For the first exponent, setting $p = 1$ and $n = 3$ we obtain
\[
1 - \frac{15}{2q-n} < -\frac{18}{7} < -\frac{3}{2},
\]
if we set $q = 3 \cdot \frac{3}{2+\tau}$, using that $\tau > \frac{1}{2}$. For the second exponent, setting $p = 1$ gives us exactly $-\frac{3}{2}$. Therefore by setting $p > 1$ close to 1 and $q > 3 \cdot \frac{3}{2+\tau}$ close to $3 \cdot \frac{3}{2+\tau}$ we obtain our desired estimate.

5 Convergence of the Yamabe flow

Using the decay rate estimates on the scalar curvature of $(M^n, g(t))$ evolving under the Yamabe flow from an initial Yamabe-positive asymptotically flat metric satisfying the hypotheses of Proposition 1.7 or 1.8 we proceed in this section.
to prove Theorem 1.3. Below we start with the unweighted convergence of the conformal factor $u(t)$ before proceeding to study its weighted convergence as $t \to \infty$.

### 5.1 Unweighted convergence

We first show that the decay rate estimate of Proposition 1.7 gives us uniform convergence to a limiting continuous function $u_\infty$.

**Lemma 5.1.** Under a Yamabe flow satisfying the hypotheses of Proposition 1.7, there exists a continuous function $u_\infty(x) > 0$ on $M$ such that

$$\|u(x, t) - u_\infty(x)\|_{L^\infty(M)} \leq \frac{C}{t^\delta}, \quad (5.1)$$

and

$$u_\infty(x) - 1 \to 0, \quad r \to \infty, \quad (5.2)$$

for all $\delta < \frac{\tau}{2}$. If the flow additionally satisfies the hypotheses of Proposition 1.8, then this holds for all $\delta < \frac{1}{2}$. (Recall from Definition 2.1 that $r \geq 1$ is a smooth function that agrees with $|x|$ in asymptotic coordinates on $M^n$.)

**Proof.** Since $\frac{\partial}{\partial t} u = -\frac{n-2}{4} R u$, we have for all $x \in M^n$ that

$$u(x, t) = e^{\int_0^t -\frac{n-2}{4} R(x,s)ds} u(x, 0).$$

By Proposition 1.7 for any $0 < \delta < \frac{\tau}{2}$,

$$|R(x, t)| \leq \frac{C}{(1 + t)^{1+\delta}}.$$

Thus for $t_1, t_2 > 1$,

$$|u(x, t_1) - u(x, t_2)| \leq C|e^{-\frac{t_1}{t_2} - \frac{t_2}{t_1}} - e^{-\frac{t_2}{t_1}}| \cdot u(x, 0)$$

$$\leq C \frac{1}{t_2^\delta} - \frac{1}{t_1^\delta} |u(x, 0)| \to 0, \quad as \ t_1, t_2 \to \infty.$$

This implies $u(x, t)$ is a Cauchy sequence in $L^\infty(M)$ as $t \to \infty$. We then immediately conclude that there exists a limiting function $u_\infty(x) \in L^\infty(M)$ which satisfies

$$\|u(x, t) - u_\infty(x)\|_{L^\infty(M)} \leq \frac{C}{t^\delta},$$

And since for each time $t > 0$,

$$|u(x, t) - 1| \leq \frac{C}{t^\delta}, \quad r \to \infty, \quad (5.3)$$

we deduce (5.2).

If we are in the setting of Proposition 1.8 then the entire argument above carries through but with $\delta < \frac{1}{2}$. \hfill $\square$
Note that we could not yet conclude above that
\[ |u_\infty(x) - 1| \leq \frac{C}{r^\tau}, \quad \text{as } r \to \infty, \]
because the bound \( C \) in (5.3) is not uniform in \( t > 0 \). But in the next two propositions we will be able to first show that \( u_\infty^4 \cdot g_0 \) is a scalar flat metric, and then show that \( u_\infty(x) - 1 \) does indeed satisfy such a spatial decay estimate.

**Proposition 5.2.** Under a Yamabe flow satisfying the hypotheses of Proposition 1.7, for all \( 0 < \alpha' < \alpha \),
\[ \| u(x,t) - u_\infty(x) \|_{C^{k+\alpha'}_{\text{loc}}} \leq \frac{C}{t^{\delta}}, \quad (5.4) \]
for any \( 0 < \delta < \tau/2 \). Moreover, \( u_\infty \in C^{k+\alpha}_{\text{loc}}(M) \) and \( g_\infty = u_\infty(x)^{\frac{4}{n-2}} g_0 \) is a scalar flat metric, i.e.
\[ \Delta_{g_0} u_\infty(x) - \frac{1}{a(n)} R_{g_0}(x) u_\infty(x) = 0. \]
Recall \( a(n) = \frac{4(n-1)}{n-2} \). If the flow additionally satisfies the hypotheses of Proposition 1.8 then (5.3) holds for all \( \delta < \frac{\tau}{2} \).

**Proof.** First recall that
\[ \frac{\partial}{\partial t} u = (n-1) \left( \frac{1}{u^{N-1}} \Delta_{g_0} u - \frac{1}{a(n)} R_{g_0}(x) u_\infty(x) \right). \]
Since we have uniform and positive upper and lower bounds on \( u \) by Lemma 3.5, and since \( R_{g_0} \in C^{k-2+\alpha}_0(M) \) we see that
\[ \left\| \frac{R_{g_0}}{u^{N-2}} \right\|_{L^\infty_{\text{loc}}(M)} \leq C, \quad \text{for all } t \in [0, \infty). \]
Thus for all \( p \geq 1 \), on any compact subset \( \Omega \subset M \),
\[ \left\| \frac{R_{g_0}}{u^{N-2}} \right\|_{L^p_{\text{loc}}(\Omega \times [t_0, t_0+1])} \leq C, \quad \text{for all } t_0 \in [0, \infty). \]
\[ \left\| u \right\|_{L^p_{\text{loc}}(\Omega \times [t_0, t_0+1])} \leq C, \quad \text{for all } t_0 \in [0, \infty). \]
We now apply the standard Schauder estimates for parabolic equations to see that \( u \) is in \( W^{2,1,p}_{\text{loc}}(\Omega \times [t_0, t_0+1]) \) and satisfies
\[ \left\| u \right\|_{W^{2,1,p}_{\text{loc}}(\Omega \times [t_0, t_0+1])} \leq C \left( \left\| \frac{R_{g_0}}{u^{N-2}} \right\|_{L^p_{\text{loc}}(\Omega \times [t_0, t_0+1])} + \left\| u \right\|_{L^\infty_{\text{loc}}(\Omega \times [t_0, t_0+1])} \right) \leq C_{2,p}, \quad \text{for all } t_0 \in [0, \infty). \]
Therefore, by the results on embedding of suitable Sobolev spaces into Hölder spaces on parabolic domains, see e.g. [Che03, Theorem 3.4],
\[
\|u\|_{C_0^{1+\alpha, \frac{2+\alpha}{2}}(\Omega \times [t_0, t_0+1])} \leq C_{1,\alpha},
\]
(5.5)
where we have chosen \( p > n + 2 \) so that \( 1 - \frac{n+2}{p} = \alpha \). The embedding constant depends on \( n, p, \text{diam}(\Omega)^{-1}, \hat{g} \) and the length of time interval (which is 1 in our case). In particular, it is independent of \( t_0 \).

To derive higher order local regularity of \( u \), we use an induction argument to prove that \( u \in C_0^{k+\alpha, \frac{2+k+\alpha}{2}}(\Omega \times [t_0, t_0+1]) \). Assuming \( u \in C_0^{l+\alpha, \frac{2+l+\alpha}{2}}(\Omega \times [t_0, t_0+1]) \), we want to show that \( u \in C_0^{l+2+\alpha, \frac{2+l+2+\alpha}{2}}(\Omega \times [t_0, t_0+1]) \) if \( l \leq k - 2 \). From (5.5), this is already proved for \( l = 0 \) and 1. Since \( R_{\theta_0} \in C_{loc}^{k-2+\alpha} \), by a product estimate for parabolic Hölder spaces we find for such \( l \) that
\[
\left\| \frac{R_{\theta_0}}{\omega^{N-2}} \right\|_{C_0^{l+\alpha, \frac{2+l+\alpha}{2}}(\Omega \times [t_0, t_0+1])} \leq C, \quad \text{for all } t_0 \in [0, \infty).
\]
Therefore by higher order Schauder estimates for parabolic equations, \( u \in C_0^{l+2+\alpha, \frac{2+l+2+\alpha}{2}}(\Omega \times [t_0, t_0+1]) \) and satisfies
\[
\begin{align*}
\|u\|_{C_0^{l+2+\alpha, \frac{2+l+2+\alpha}{2}}(\Omega \times [t_0, t_0+1])} & \leq C \left( \left\| \frac{R_{\theta_0}}{\omega^{N-2}} \right\|_{C_0^{l+\alpha, \frac{2+l+\alpha}{2}}(\Omega \times [t_0, t_0+1])} + \|u\|_{L_\infty^\alpha(\Omega \times [t_0, t_0+1])} \right) \\
& \leq C_{l+2,\alpha}, \quad \text{for all } t_0 \in [0, \infty).
\end{align*}
\]
The induction argument stops when \( l = k - 2 \).

Hence we have proved that \( u \in C_0^{k+\alpha, \frac{2+k+\alpha}{2}}(\Omega \times [t_0, t_0+1]) \). Taking \( j = 0 \) and \( t = t_0 \) in Definition A.1, we obtain
\[
\|u(x, t)\|_{C_0^{k+\alpha}(\Omega)} \leq C_{k+\alpha}, \quad \text{for all } t \in [0, \infty).
\]
Note that \( C_{k,\alpha} \) depends on \( \Omega, k, \alpha \), and is independent of \( t \), so for every \( 0 < \alpha' < \alpha \) and every sequence \( \{t_j\} \to \infty \), there exist a subsequence \( \{t_{j_k}\} \to \infty \) and a limiting function \( u_\infty(x) \) such that
\[
u(x, t_{j_k}) \to u_\infty(x) \quad \text{in } C_{loc}^{k+\alpha'}, \quad \text{as } t \to \infty,
\]
(5.6)
by the Arzela–Ascoli theorem. But by Lemma 5.1 we also have
\[
u(x, t) \to u_\infty(x) \quad \text{in } L_\infty(M), \quad \text{as } t \to \infty.
\]
Thus \( u_\infty \equiv u_\infty \), and this implies
\[
u(x, t) \to u_\infty(x) \quad \text{in } C_{loc}^{k+\alpha'}, \quad \text{as } t \to \infty,
\]
23
Since \( k \geq 2 \), we can pass the limit in the scalar curvature equation to see that \( u_\infty(x) \frac{4}{n-2} g_0 \) is a scalar flat metric, i.e.

\[
\Delta_{g_0} u_\infty - \frac{1}{a(n)} R_{g_0} u_\infty = 0.
\]

Finally, we claim that \( u_\infty(x) \in C_{loc}^{k+\alpha} \), even though the sequence does not converge in this space as in (5.6). This is because the \( C_{0}^{k+\alpha}(\Omega) \) norm is lower semicontinuous. Namely, for any compact subset \( \Omega \subset \subset M \),

\[
\|u_\infty(x)\|_{C_{0}^{k+\alpha}(\Omega)} \leq \lim_{t \to \infty} \|u(x, t)\|_{C_{0}^{k+\alpha}(\Omega)} \leq C_{k, \alpha}.
\]

We now have enough information to conclude that \( u_\infty \) is in fact the conformal factor \( \phi \) from Proposition 3.1 corresponding to the scalar-flat metric \( \tilde{g} \).

**Proposition 5.3.** We have \( u_\infty - 1 \in C_{-\tau}^{k+\alpha} \). In particular,

\[
|u_\infty(x) - 1| \leq C \frac{r}{r^\tau}, \quad \text{as } r \to \infty,
\]

and

\[
|\partial_j u_\infty(x)| \leq C \frac{r}{r^{1+\tau}}, \quad \text{as } r \to \infty.
\]

**Proof.** By Proposition 3.2 there exists a positive function \( \phi \) with \( \phi - 1 \in C_{-\tau}^{k+\alpha} \) such that \( \tilde{g} = \phi^{\frac{4}{n-2}} g_0 \) scalar flat. Since \( u_\infty g_0 \) is also scalar flat, the function \( w := u_\infty \cdot \phi^{-1} \) will satisfy

\[
\Delta_{\tilde{g}} w(x) = 0.
\]

Moreover, by Lemma 5.1 \( w(x) - 1 \to 0 \) as \( r \to \infty \). Thus the maximum principle asserts that \( w \equiv 1 \), so that \( u_\infty - 1 = \phi - 1 \in C_{-\tau}^{k+\alpha} \). \( \square \)

We can now prove Theorem 1.2.

**Proof of Theorem 1.2.** Part (1) of Theorem 1.2 follows immediately from combining the results of Propositions 5.2 and 5.3.

To see Part (2), notice that all we have used to prove Part (1) is that \( u(t) \) remains uniformly bounded from above and below for all times. So if \( Y(M, [g_0]) \leq 0 \) but \( u(t) \) remains uniformly bounded from above and below, then Lemma 5.1 and Proposition 5.2 again show that \( u(t) \) converges uniformly to some \( u_\infty \in C_{loc}^{k+\alpha}(M) \), asymptotic to 1 at spatial infinity. But by the conformal invariance of the Yamabe constant, we have

\[
Y(M, [g_0]) = \inf_{v \in C^\infty_0(M), v \neq 0} \frac{\frac{4n-4}{n-2} \int_M |\nabla_{g_\infty} v|^2 dV_{g_\infty}}{\left( \int |v|^{\frac{4n}{n-2}} dV_{g_\infty} \right)^{\frac{n-2}{n}}} = \frac{1}{C_{g_\infty}} > 0,
\]

(5.9)
where the $L^2$ Euclidean-type Sobolev constant $C_{g_\infty}$ of $g_\infty$ exists because $u_\infty$ is asymptotic to 1 at spatial infinity. This contradicts our initial assumption on the Yamabe constant of $(M, [g_0])$. Therefore from the proof of Lemma 3.4 we see that we must in fact have $\sup_{x \in M} u(x,t) \xrightarrow{t \to \infty} \infty$.

It remains to show that the $L^2$ Euclidean-type Sobolev constant of $(M, g(t))$ also blows up as $t \to \infty$. If not, then we have uniform control of this constant, which allows us to carry out nearly all the arguments of Section 4 (without any assumption on the boundedness of $u(t)$) until Proposition 1.6 where we passed from (4.15) to (4.16) using the $L^\infty$ bound of $R$, which was a consequence of the uniform bounds on $u$ established when $Y(M, [g]) > 0$. But we can recover the boundedness of $R$ simply with the bound on the Sobolev constant by plugging the uniform bound of $\|R\|_{L^p}$ for $p$ slightly larger than $\frac{n}{2}$ from Lemma 4.3 into the estimate of Proposition 1.4. In fact the constant in that estimate only depends on the Sobolev constant bound $D$ of $g_0$, so since we are now assuming control of the Sobolev constant we obtain the same estimates for $\|R\|_{L^\infty}$ on the intervals $[T, T+1]$ for all $T \in \mathbb{Z}_{\geq 0}$, and hence uniform bound of $R$ for all times. As a result, we can continue through the same arguments we used to prove $u(t)$ is unbounded earlier. Note that although Proposition 5.2 uses the boundedness of $u(t)$, we do actually obtain this beforehand when we integrate in proving Lemma 5.1.

5.2 Weighted convergence

We will now prove the weighted convergence of Yamabe flows starting from AF manifolds with $Y(M^n, [g_0]) > 0$, and need to assume for the rest of this section that $\tau > 1$ as in Theorem 1.3 or that $n = 3$, $\tau > \frac{1}{2}$, $R_{g_0} \geq 0$, and $R_{g_0} \in L^1(M^n, g_0)$ as in Theorem 1.4. The difference between the proofs of Theorems 1.3 and 1.4 occurs with the distinct decay rate estimates, Propositions 1.7 and 1.8, required to prove Proposition 5.4 below in the respective settings of the two Theorems. In particular, the decay rate of $R$ from Proposition 1.7 alone is not enough to give us the estimates of Lemma 5.5 when $n = 3$ and $\tau > \frac{1}{2}$, so for this case we must bring in the improved estimate of Proposition 1.8.

Using a strategy similar to that used to prove [Li18, Lemma 5.2] in a Ricci flow setting, we now prove below Proposition 5.4 a decay estimate for the scalar curvature in both space and time. In fact, once we have this, the rest of the proofs of Theorems 1.3 and 1.4 are the same, and we will complete the proofs of both together at the end of this section.

**Proposition 5.4.** Under the hypotheses of either Theorem 1.3 or Theorem 1.4, for any $\tau' < \tau$ there exists some $\delta_0 > 0$ and $C>0$ depending only on $g_0$ such that

$$|R(x,t)| \leq \frac{C}{r^{\tau'}(1+t)^{1+\delta_0}}$$

(5.10)

for all $(x,t) \in M \times [0,\infty)$ along the flow.
Proof. Given $\tau' < \tau$, choose $\sigma_0, \sigma_1$ such that $\tau' < \sigma_1 < \sigma_0 < \tau$. Let $\delta = \frac{\sigma_0}{2}$, and consider $D := \{(x,t) \in M \times [0, \infty) : r(x) \geq t^a\}$ where $a > 1/2$ is to be determined.

For $(x,t) \notin D$, by Proposition 1.7

$$|R| \leq Ct^{1-\delta} \leq Ct^{-\eta' \tau' - \tau'}$$

for some $\eta > 0$, when $a > 1/2$ but is close enough to 1/2.

We now claim the estimate

$$|R| \leq Cr^{-\sigma_1} \quad \text{for } (x,t) \in D$$

holds. In fact, we define $h := r^{4+2\sigma_1}$ and $w = h \cdot |R|^2$. Then $w$ satisfies the evolution equation

$$\left(\frac{\partial}{\partial t} - (n-1)\Delta\right) w \leq (n-1)(Bw - 2\nabla \log h \cdot \nabla w) + 2h|R|^3. \quad (5.11)$$

Here $B := \frac{2(\nabla h^2 - h \Delta h)}{h^2}$. From Lemma 5.5 below, for any $\beta < \frac{1}{2}$ we can bound $B$ uniformly by $C(r^{-2} + r^{-1}t^{-3}) \leq Ct^{-\frac{\beta}{2} - \frac{3}{4}}$ on $D$, by choosing $\beta$ sufficiently close to $\frac{1}{2}$. By Proposition 1.7

$$h|R|^3 \leq w \cdot t^{-1-\delta} = w \cdot t^{-1-\frac{\sigma_0}{2}}.$$

Thus (5.11) becomes

$$\left(\frac{\partial}{\partial t} - (n-1)\Delta\right) w \leq -2(n-1)\nabla \log h \cdot \nabla w + Cw \cdot t^{-1-\delta_0},$$

where $\delta_0 := \min\{\frac{a}{2} - \frac{1}{4}, \frac{\sigma_0}{2}\} > 0$.

On $\partial D$, we have

$$|R| \leq Ct^{-1-\delta_0} = Cr^{-(1+\delta_0)/a} \leq Cr^{-2-\sigma_1}$$

for $a$ sufficiently close to 1/2. So we can apply the maximum principle on the noncompact manifold as in [Cho+08, Theorem 12.14] to conclude the claim holds. (See also the statement in [Li18, Theorem 2.1].)

Therefore on $D$ we have

$$|R| \leq Cr^{-2-\sigma_1} \leq Ct^{-1-\delta_0 \tau' - \tau'},$$

for some $\delta_0 > 0$ and $a$ sufficiently close to 1/2.

Lemma 5.5. Under the hypotheses of either Theorem 1.3 or Theorem 1.4 for $r(x) >> 1, t >> 1$ and any $\beta < \frac{1}{2}$,

$$|\nabla g(t)h|g(t) \leq C|\nabla g_0h|g(0) \leq \frac{Ch}{r}, \quad (5.12)$$

$$|\Delta g(t)h| \leq \frac{Ch}{r} \cdot \left(\frac{1}{r} + \frac{1}{u^2}\right). \quad (5.13)$$
Proof. (5.12) is straightforward as $u$ is uniformly bounded by Lemma 3.5 and

$$|\nabla_g h|_{g(t)} = u^{-\frac{n-2}{2}}|\nabla_{g_0} h|_{g(0)}.$$  

Regarding (5.13), we consider

$$\Delta_g h = u^{-\frac{n-2}{2}} \Delta g_0 h + 2u^{-\frac{n+2}{2}} g_0^{ij} \partial_i h \partial_j u. \quad (5.14)$$

We know from calculation

$$\Delta g_0 h \leq \frac{Ch}{r^2}, \quad (5.15)$$

and

$$\partial_i h \leq \frac{Ch}{r}. \quad (5.16)$$

The next step is to estimate $\partial_j u$. From the proof of Proposition 5.2, formula (5.4), we see

$$\|u(x, t) - u_\infty(x)\|_{C^{k+\alpha'}_{1+\tau'}} \leq \frac{C}{t^{\beta}},$$

for any $0 < \delta < \tau/2$. On the other hand, by (5.7) from Proposition 5.3 we have $|\partial_j u_\infty(x)| \leq \frac{C}{r^{1+\tau}}$. Recall that in the $n = 3$ case where we imposed additional assumptions on $R_{g_0}$ we can replace the restriction on $\delta$ by $0 < \delta < \frac{1}{2}$, and this also holds when $n \geq 4$ since we assumed in this case that $\tau > 1$.

So putting these estimates together we can obtain for any dimension $n \geq 3$ and any $\beta < \frac{1}{2}$ that

$$|\partial_j u(x, t)| \leq C \left( \frac{1}{t^\beta} + \frac{1}{r^{1+\tau}} \right) \leq C \left( \frac{1}{t^\beta} + \frac{1}{r} \right). \quad (5.17)$$

Then, plugging (5.15), (5.16), (5.17) into (5.14), we complete the proof of (5.13).

Now that we have weighted decay of the scalar curvature, by integrating we can start to prove the weighted convergence of the conformal factor $u(t)$.

**Proposition 5.6.** Under the hypotheses of either Theorem 1.3 or Theorem 1.4, for any $\tau' < \tau$ we have

$$u(x, t) - u_\infty(x) \to 0 \quad \text{in} \ C^0_{-\tau'}, \quad \text{as} \ t \to \infty,$$

where $u_\infty \in C^{k+\alpha}_{-\tau}$ is as in Proposition 5.2. Moreover, there is a $\delta_0 > 0$ such that

$$\|u(x, t) - u_\infty(x)\|_{C^{\alpha}_{-\tau'}} \leq \frac{C}{\delta_0}. \quad (5.18)$$
Proof. Since \( \frac{\partial}{\partial t} u = -\frac{n-2}{4} Ru \), we have
\[
u(x,t) = e^{\int_0^t -\frac{n-2}{4} R(x,s) ds} u(x,0).
\] (5.19)

By Proposition 5.4,
\[
|R(x,t)| \leq C r^{\tau'} (1 + t)^{1+\delta_0}.
\] (5.20)

Thus for \( t_1, t_2 \gg 1 \),
\[
|u(x,t_1) - u(x,t_2)| \leq C e^{r^{\tau'}} \cdot \left| \frac{e^{\frac{t}{t_1^0}} - e^{\frac{t}{t_2^0}}}{t_1^0 - t_2^0} \right| \cdot |u(x,0)|
\]
\[
\leq C \frac{1}{r^{\tau'}} \cdot \left| \frac{1}{t_1^0} - \frac{1}{t_2^0} \right| \cdot |u(x,0)|.
\]
This implies
\[
r^{\tau'} \cdot |u(x,t_1) - u(x,t_2)| \leq C \frac{1}{t_1^0} - \frac{1}{t_2^0} \to 0, \text{ as } t_1, t_2 \to \infty.
\]

Note that \( u(x,t) - 1 \in C_{0,\tau'}^0 \) for every \( t > 0 \) by [CZ15, Theorem 1.3]. Thus \( u(x,t) - 1 \) is a Cauchy sequence in \( C_{0,\tau'}^0 \) as \( t \to \infty \). We may then conclude that
\[
\|u(x,t) - u_{\infty}(x)\|_{C_{0,\tau'}^0} \leq \frac{C}{t^{\delta_0}}.
\]

Before proceeding to the proof of Theorem 1.3, we need to establish some uniform control of the conformal factor \( u(t) \) in some parabolic weighted Sobolev and Hölder spaces.

Lemma 5.7. Under the hypotheses of either Theorem 1.3 or Theorem 1.4 and for any \( \tau' \leq \tau \):

(1) For any \( p > 1 \), there exists a constant \( C > 0 \) such that for any \( 0 < \tau_1 < \tau' \) and all \( t_0 \geq 0 \)
\[
\|u - 1\|_{W^{k,k/2,p}(M \times [t_0,t_0+1])} \leq C.
\]

(2) There exists a constant \( C > 0 \), such that for all \( t_0 \geq 0 \)
\[
\|u - 1\|_{C_{0,\tau'}^{k+\alpha, \frac{1+k+\alpha}{2} \delta_0}(M \times [t_0,t_0+1])} \leq C.
\]

Here \( C \) is independent of time \( t_0 \).
Proof. To estimate \( \|u - 1\|_{W^{k,k/2,p}(M \times [t_0,t_0+1])} \), we observe that \( u - 1 \) satisfies the equation
\[
Na^{N-1} \frac{\partial}{\partial t}(u - 1) = \Delta g_0 (u - 1) - a(n)R_{g_0}(u - 1) + a(n)R_{g_0},
\]

where \( a(n) = \frac{n-2}{4n-1} \). By Proposition A.5 in the Appendix,
\[
\|u - 1\|_{W^{k,k/2,p}(M \times [t_0,t_0+1])} \leq C \left( \|R_{g_0}\|_{W^{k-k/2-1,p}(M \times [t_0,t_0+1])} + \|u - 1\|_{L^p(M \times [t_0,t_0+1])} \right).
\]

Since \( R_{g_0} \in C^{k-2+\alpha}(M) \) and \( R_{g_0} \) is independent of \( t \),
\[
\|R_{g_0}\|_{W^{k-k/2-1,p}(M \times [t_0,t_0+1])} \leq C.
\]

Thus it suffices to prove that \( \|u - 1\|_{L^p(M \times [t_0,t_0+1])} \leq C \).

Recall (5.19) and (5.20) from the proof of Theorem 5.6:
\[
u(x,t) = e_{f_0} - \frac{n-2}{4} R(x,t) dt u(x,0),
\]
and
\[
|R(x,t)| \leq \frac{C}{r^\gamma(1+t)^{1+\theta_0}}.
\]

We also know from the AF assumption on \( g_0 \) that
\[
|u(x,0) - 1| \leq \frac{C}{r^\gamma}.
\]

Thus
\[
u(x,t) - 1 | \leq e_{f_0} - \frac{n-2}{4} R(x,t) dt \cdot |u(x,0) - 1| + |e_{f_0} - \frac{n-2}{4} R(x,t) dt - 1| \leq C \cdot |u(x,0) - 1| + C \left| \int_0^t -R(x,t) dt \right|
\]
\[
\leq \frac{C}{r^\gamma}.
\]

Above in the second line of (5.22), we have used \( |e^s - 1| \leq e^{|s|} \cdot |s| \), where \( s \) is some point in \([0,s]\), so that \( |e^s - 1| \leq e^{|s|} \cdot |s| \). Letting \( s = \int_0^t -\frac{n-2}{4} R(x,t) dt \) so that \( |s| \leq \frac{C}{r^\gamma(1+t)^{1+\theta_0}} \leq C \) by (5.21) gives us the estimate.

As a result we see that \( u - 1 \in C^{0}_{\gamma}(M \times [t_0,t_0+1]) \leftrightarrow L^p_{\gamma_1}(M \times [t_{0},t_{0} + 1]) \), for any \( \gamma_1 < \gamma \), completing the proof of (1).

To prove (2), again by Proposition A.5 in the Appendix we have
\[
\|u - 1\|_{C^{k+\alpha}_{\gamma_{1}}(M \times [t_{0},t_{0} + 1])} \leq C \left( \|R_{g_0}\|_{C^{k+\alpha}_{\gamma_{1}}(M \times [t_{0},t_{0} + 1])} + \|u - 1\|_{C^{0}_{\gamma_{1}}(M \times [t_{0},t_{0} + 1])} \right).
\]
Since \( u - 1 \in C_{-\tau}^0(M \times [t_0, t_0 + 1]) \) and \( R_{g_0} \in C_{-\tau - 2}^{k-2+\alpha}(M) \) we obtain our desired estimate.

Now we are ready to prove Theorems 1.3 and 1.4.

**Proof of Theorems 1.3 and 1.4.** We will bootstrap to inductively prove higher global regularities of \( \phi \) in weighted parabolic Hölder spaces. More precisely, we want to show the following estimate: for all \( l \leq k \) and \( \tau' < \tau \) (assuming as throughout this section that \( \tau < n - 2 \)),

\[
\| \phi(x, t) \|_{C_{-\tau'}^{l+\alpha}(M \times [t_0, t_0 + 1])} \leq \frac{C}{t_0^{\delta_0}}. \tag{5.23}
\]

**Claim 1:** (5.23) holds for \( l = 0 \).

Let \( \phi(x, t) = u(x, t) - u_\infty(x) \). Subtracting the two equations that \( u(x, t) \) and \( u_\infty(x) \) satisfy,

\[
\frac{\partial}{\partial t} u^N = (n - 1) N \Delta g_0 u - \frac{1}{a(n)} R_{g_0}(x) u
\]

and

\[
\Delta g_0 u_\infty(x) - \frac{1}{a(n)} R_{g_0}(x) u_\infty(x) = 0,
\]

we obtain

\[
\frac{\partial}{\partial t} \phi(x, t) = \frac{n - 1}{u^N - 1} [\Delta g_0 \phi(x, t) - \frac{1}{a(n)} R_{g_0}(x) \phi(x, t)]. \tag{5.24}
\]

By (5.18) of Proposition 5.6 there is a \( \delta_0 > 0 \) such that

\[
\| \phi(x, t) \|_{C_{-\tau}^0(M)} \leq \frac{C}{t_0^{\delta_0}}.
\]

Therefore for all \( p \geq 1 \) and \( \tau_1 < \tau' \),

\[
\| \phi(x, t) \|_{L^p_{\tau_1} (M \times [t_0, t_0 + 1])} \leq \frac{C}{t_0^{\delta_0}}, \tag{5.25}
\]

where \( C \) depends only on \( p \geq 1 \) and \( g_0 \) (but is independent of \( t_0 \)).

Since \( u(x, t) - 1 \in C_{-\tau}^0(M) \) and \( 0 < C_1 \leq u(x, t) \leq C_2 < \infty \), we have \( \frac{1}{u(x, t)} - 1 \in C_{-\tau}^0(M) \) as well. We also have \( R_{g_0} \in C_{-\tau - 2}^{k-2+\alpha}(M) \). Hence, by the triangle inequality and the product estimate from Lemma A.3,

\[
\frac{R_{g_0}(x)}{u^{N-1}(x, t)} = R_{g_0}(x) \cdot \left( \frac{1}{u^{N-1}(x, t)} - 1 \right) + R_{g_0}(x) \in C_{-\tau - 2}^0(M),
\]

and thus for all \( 0 < \tau_1 < \tau' \), \( \frac{R_{g_0}(x)}{u^{N-1}(x, t)} \in L^p_{\tau_1-2} (M \times [t_0, t_0 + 1]) \).
Putting everything together, we obtain that for any $t_0 > 0$ that
\[
\| R_{g_0} \phi \|_{L^p_{-\tau_1-2}(M \times [t_0, t_0+1])} \leq C \frac{t_0}{t_0^0}.
\]
(5.26)

Now by the weighted Schauder estimate for parabolic equations from [CZ15, Theorem 5.3] (or see Proposition A.5) applied to (5.24), we have for each $t_0 > 0$ that
\[
\| \phi \|_{W^{2,1,p}(M \times [t_0, t_0+1])} \leq C \frac{t_0}{t_0^0}.
\]
(5.27)

so substituting (5.26) and (5.25) into (5.27), we derive
\[
\| \phi(x,t) \|_{W^{2,1,p}(M \times [t_0, t_0+1])} \leq C \frac{t_0}{t_0^0}.
\]
(5.28)

Since (5.28) holds for all $p \geq 1$, we have by Sobolev embedding results for parabolic weighted spaces that (see statement III of Lemma A.2),
\[
\| \phi(x,t) \|_{C^{\frac{\alpha}{\tau_1}}(M \times [t_0, t_0+1])} \leq C \frac{t_0}{t_0^0}.
\]
(5.29)

Claim 2: If (5.23) is valid for $l + 2$ when $l \leq k - 2$. Again from the evolution equation for $\phi$ and the weighted Schauder estimates of Proposition A.5 we have
\[
\| \phi(x,t) \|_{C^{l+2+\frac{n+2}{\tau_1}}(M \times [t_0, t_0+1])} \leq C \frac{t_0}{t_0^0},
\]
(5.30)

where $C = C(\alpha, \tau_1)$ and we have chosen $p > n + 2$ so that $1 - \frac{n+2}{\tau_1} = \alpha$. From (5.18) we have
\[
\| \phi \|_{C^{\frac{\alpha}{\tau_1}}(M \times [t_0, t_0+1])} \leq C \frac{t_0}{t_0^0},
\]
(5.31)

So it remains to show that
\[
\| R_{g_0} \phi \|_{C^{l+\alpha, \frac{\alpha}{\tau_1}}_{-\tau_1-2}(M \times [t_0, t_0+1])} \leq C \frac{t_0}{t_0^0}.
\]
(5.32)
In fact, by the product estimate of Lemma A.3 along with Lemma 5.7 and the fact that \( u - 1 \in C^{l+\alpha, \frac{1}{2}}_{-n}(M \times [t_0, t_0 + 1]) \) for \( l \leq k - 2 \),
\[
\| R_{g_0} \left( \frac{1}{u^{N-1}} - 1 \right) \|_{C^{l+\alpha, \frac{1}{2}}_{-n'}(M \times [t_0, t_0 + 1])} \leq C \| R_{g_0} \|_{C^{l+\alpha, \frac{1}{2}}_{-n'}(M \times [t_0, t_0 + 1])} \| u - 1 \|_{C^{l+\alpha, \frac{1}{2}}_{0}(M \times [t_0, t_0 + 1])} \leq C,
\]
and also have \( R_{g_0} \in C^{k+\alpha, \frac{1}{2}}_{-n}(M \times [t_0, t_0 + 1]) \) for all \( l \leq k - 2 \).
Therefore
\[
\frac{R_{g_0}}{u^{N-1}} = R_{g_0} \left( \frac{1}{u^{N-1}} - 1 \right) + R_{g_0} \in C^{l+\alpha, \frac{1}{2}}_{-n'}(M \times [t_0, t_0 + 1]).
\]
Hence (5.30) follows as
\[
\frac{R_{g_0} \phi}{u^{N-1}} \cdot \phi(x, t) \leq C \frac{R_{g_0}}{u^{N-1}} \cdot \phi(x, t) \leq C \frac{R_{g_0}}{u^{N-1}} \cdot \phi(x, t) \leq C \frac{R_{g_0}}{t_0} (\phi(x, t) \cdot \phi(x, t)) \leq \frac{A_k}{C^{n_0}}.
\]
Above, the last inequality uses the inductive hypothesis (5.23). By substituting (5.31) into (5.32) we have proved Claim 2.

Claim 1 and 2 together complete the proof of (5.23). To conclude, in the definition of the \( C^{k+\alpha, \frac{1}{2}}_{-n'}(M \times [t_0, t_0 + 1]) \) spaces as stated in Definition A.1 of the Appendix we can take \( j = 0 \) and \( t = t_0 \), and derive for all \( t > 0 \),
\[
\| \phi(x, t) \|_{C^{k+\alpha}_{-n'}(M)} \leq \| \phi(x, t) \|_{C^{k+\alpha, \frac{1}{2}}_{-n'}(M \times [t_0, t_0 + 1])} \leq \frac{A_k}{C^{n_0}},
\]
and thus
\[
u(x, t) - 1 \rightarrow u_\infty(x) - 1 \text{ in } C^{k+\alpha}_{-n'}(M) \text{ as } t \rightarrow \infty.
\]

**A C^{k+\alpha}_{-n'} AF metrics along the Yamabe flow**

Here we prove Theorem 2.6 — namely, we check that a \( C^{k+\alpha}_{-n'} \) AF metric, \( k \geq 2 \), continues to be a \( C^{k+\alpha}_{-n'} \) AF metric along a fine solution of the Yamabe flow. First we need to recall the definitions of some parabolic Hölder spaces from [CZ15].

**Definition A.1** (see [CZ15, Definition 4.1]). Let \((M^n, g)\) be a complete Riemannian manifold such that there exists a compact \( K \subseteq M^n \) and a diffeomorphism \( \Phi: M^n \setminus K \rightarrow \mathbb{R}^n \setminus B_{R_0}(0) \), for some \( R_0 > 0 \). Let \( r \geq 1 \) be a smooth function on
that agrees under the identification \( \Phi \) with the Euclidean radial coordinate \(|x|\) in a neighborhood of infinity, and let \( \hat{g} \) be a smooth metric on \( M^n \) which is equal to the Euclidean metric in a neighborhood of infinity under the identification \( \Phi \). Let \( \mathcal{M} = M^n \times [0,T] \). Then with all quantities below computed with respect to the metric \( \hat{g} \), we have the following function spaces:

The weighted Lebesgue spaces \( L^q_\beta(\mathcal{M}) \), for \( q \geq 1 \) and weight \( \beta \in \mathbb{R} \), consist of those locally integrable functions on \( \mathcal{M} \) for which the following respective norms are finite:

\[
\|v\|_{L^q_\beta(\mathcal{M})} = \left\{ \begin{array}{ll}
\left( \int_0^T \int_M |v|^{q} r^{-\beta} q^{-n} dx \right)^{\frac{1}{q}}, & q < \infty, \\
\text{ess sup}_M (r^{-\beta} |v|), & q = \infty.
\end{array} \right.
\]

The weighted Sobolev spaces \( W^{k,k/2,q}_\beta(\mathcal{M}) \) are then defined in the usual way with the norms

\[
\|v\|_{W^{k,k/2,q}_\beta(\mathcal{M})} = \sum_{i+2j \leq k} \left\| \sum_{i+j \leq k} D_x^i D_t^j v \right\|_{L^q_{\beta-2j}(\mathcal{M})}.
\]

The weighted \( C^k \) spaces \( C^k_\beta(\mathcal{M}) \) consist of the \( C^k \) functions for which the following respective norms are finite:

\[
\|v\|_{C^k_\beta(\mathcal{M})} = \sum_{i+2j \leq k} \sup_{(x,t) \in \mathcal{M}} r^{-\beta+i+2j} |D_x^i D_t^j v|.
\]

The weighted Hölder spaces \( C^{k+\alpha,(k+\alpha)/2}_\beta(\mathcal{M}) \), \( \alpha \in (0,1) \), consist of those \( v \in C^k_\beta(\mathcal{M}) \) for which the following respective norms are finite:

\[
\|v\|_{C^{k+\alpha,(k+\alpha)/2}_\beta(\mathcal{M})} = \|v\|_{C^k_\beta(\mathcal{M})} + [v]_{C^{k+\alpha}_\beta(\mathcal{M})} + \langle v \rangle_{C^{k+\alpha}_\beta(\mathcal{M})}.
\]

Here,

\[
[v]_{C^{k+\alpha}_\beta(\mathcal{M})} = \sum_{i+j=k} \sup_{(x,t) \neq (y,s) \in \mathcal{M}} \min(r(x), r(y))^{-\beta+i+2j+\alpha} \left| D_x^i D_t^j v(x,t) - D_x^i D_t^j v(y,s) \right| \delta((x,t),(y,s))^{\alpha},
\]

where \( \delta((x,t),(y,s)) = d(x,y) + |t-s|^{\frac{1}{2}} \), and for \( k \geq 1 \),

\[
\langle v \rangle_{C^{k+\alpha}_\beta(\mathcal{M})} = \sum_{i+j=k-1} \sup_{(x,t) \neq (y,s) \in \mathcal{M}} r(x)^{-\beta+i+2j+\alpha+1} \left| D_x^i D_t^j v(x,t) - D_x^i D_t^j v(x,s) \right| |t-s|^{\frac{2+\alpha}{2}}.
\]
We now record some embedding results for the spaces above from [CZ15, Theorem 4.5]. Note that (iii) below is a sharpened version of an embedding result which appears in the proof of [CZ15, Theorem 1.3].

Lemma A.2. Under the hypotheses of Definition A.1, the following inequalities hold:

(i) For $1 \leq p < q \leq \infty$ and $\beta_2 < \beta_1$, we have
\[ \|v\|_{L^p_{\beta_1}(\mathcal{M})} \leq C \|v\|_{L^q_{\beta_2}(\mathcal{M})}. \]

(ii) For $\beta = \beta_1 + \beta_2$, $1 \leq p, q, s \leq \infty$, and $\frac{1}{p} = \frac{1}{q} + \frac{1}{s}$, we have
\[ \|v\|_{L^p_{\beta}(\mathcal{M})} \leq \|v\|_{L^q_{\beta_1}(\mathcal{M})} \|v\|_{L^s_{\beta_2}(\mathcal{M})}. \]
and
\[ \|v\|_{C^{\alpha,\alpha/2}_{\beta}(\mathcal{M})} \leq \|v\|_{C^{\alpha,\alpha/2}_{\beta_1}(\mathcal{M})} \|v\|_{C^{\alpha,\alpha/2}_{\beta_2}(\mathcal{M})}. \] (A.3)

(iii) For $p > n + 2$ and $\alpha = 1 - \frac{n+2}{p}$, we have
\[ \|v\|_{C^{\alpha,\alpha/2}_{\beta}(\mathcal{M})} \leq \|v\|_{W^{2,1,\frac{p}{2}}_{\beta}(\mathcal{M})}. \]

We next state some generalizations of product inequalities for the weighted parabolic Sobolev and Hölder norms found in [CZ15, Theorem 4.5]. They follow from the definitions of these weighted norms. In the Hölder case one must check that $C^{k+\alpha,(k+\alpha)/2}_{\beta} \hookrightarrow C^{j+\alpha,(j+\alpha)/2}_{\beta}$ for all $0 \leq j \leq k$.

Lemma A.3. Let $\beta = \beta_1 + \beta_2$ with $\beta_1, \beta_2 \leq 0$.

(i) For $1 \leq p, q, s \leq \infty$ with $\frac{1}{p} = \frac{1}{q} + \frac{1}{s}$ and a given nonnegative integer $k$, we have
\[ \|uv\|_{W^{k,1/p}_{\beta}(\mathcal{M})} \leq C_1 \|u\|_{W^{k,1/p}_{\beta_1}(\mathcal{M})} \|v\|_{W^{k,1/p}_{\beta_2}(\mathcal{M})}, \]
where $C_1$ depends on $\mathcal{M}$ and $k$.

(ii) For $k \geq 0$, we have
\[ \|uv\|_{C^{k+\alpha,(k+\alpha)/2}_{\beta}(\mathcal{M})} \leq C_2 \|u\|_{C^{k+\alpha,(k+\alpha)/2}_{\beta_1}(\mathcal{M})} \|v\|_{C^{k+\alpha,(k+\alpha)/2}_{\beta_2}(\mathcal{M})}, \]
where $C_2$ depends on $\mathcal{M}$ and $k$.

We now check that an unweighted Hölder estimate holds for the conformal factor $u$ which evolves along the Yamabe flow.
Lemma A.4. Let \( g(t) \) be a fine solution of the Yamabe flow starting from the asymptotically flat manifold \((M^n, g_0)\) on the maximal time interval \([0, T_0]\), given by \( g(t) = u(t)^{-\frac{4}{n-2}} g_0 \) with \( u(0) \equiv 1 \), and let \( T < T_0 \). Then given \( r_0 > 0 \), there exists a sequence \( A_k > 0 \) for \( k = 1, 2, \ldots \), such that

\[
\|u\|_{C^{k,\alpha,(k+\alpha)/2}(B_{r_0}(p),[0,T])} \leq A_k,
\]

independently of the point \( p \in M \). Hence there exist uniform bounds on \([0,T]\) for the curvature \( R_m \) and all of its derivatives.

Proof. By [CZ15, Theorem 2.4], on a given \([0,T]\) the conformal factor \( u(x,t) \) satisfies \( 0 < c_1 \leq u(x,t) \leq c_2 \) for some constants \( c_1, c_2 \). Therefore we may apply the Krylov-Safonov estimate for parabolic equations to (2.3) and then repeatedly apply the Schauder estimates for parabolic equations (see for instance [Lie96, Theorem 4.9]) to obtain the conclusion.

With the help of the product inequalities of Lemma A.3 we can then adapt the arguments in the proof of [CZ15, Theorem 5.4] to establish higher-order weighted Sobolev and Hölder estimates for the conformal factor \( u(t) \).

Proposition A.5. Let \( u(x,t) \) be a fine solution of the Yamabe flow starting from an asymptotically flat manifold \((M^n, g_0)\) on the maximal time interval \([0,T_0]\), given by \( g(t) = u(t)^{-\frac{4}{n-2}} g_0 \) with \( u(0) \equiv 1 \). Further let \( v = 1 - u \), and suppose for a fixed \( T < T_0 \) that \( 0 < \delta \leq u(x,t) \leq C' \) on \([0,T]\).

(i) If \((M^n, g_0)\) is \( W^{k,p} \) asymptotically flat for some \( k \geq 2 \), then there exists \( C = C(n,k,p,\tau,\delta,C') \) such that

\[
\|v\|_{W^{k,p}_{-\tau/2,p}(\mathcal{M})} \leq C \left( \| R_{g_0} \|_{W^{-2,k/2-1,p}(\mathcal{M})} + \| v \|_{L^p_{-\tau}(\mathcal{M})} \right).
\]

(ii) If \((M^n, g_0)\) is \( C^{\frac{k}{\tau}+\alpha} \) asymptotically flat for some \( k \geq 2 \), and we have

\[
\|v\|_{C^{\frac{k}{\tau}+\alpha,(k-2+\alpha)/2}_{0}(\mathcal{M})} \leq C'',
\]

then there exists \( C = C(n,k,\tau,\delta,C',C'') \) such that

\[
\|v\|_{C^{k,\alpha,(k+\alpha)/2}_{-\tau}(\mathcal{M})} \leq C \left( \| R_{g_0} \|_{C^{\frac{k}{\tau}-2+\alpha,(k-2+\alpha)/2}(\mathcal{M})} + \| v \|_{C^{\alpha}_{-\tau}(\mathcal{M})} \right) \quad (A.4)
\]

Proof. The proofs of (i) and (ii) similar and moreover are straightforward adaptations of the proofs of Theorems 5.3 and 5.4 respectively in [CZ15], once we have the multiplicative inequalities of Lemma A.3. Indeed the statements of [CZ15, Theorems 5.3, 5.4] are exactly the statements of Proposition A.5 in the case \( k = 2 \). As a result we will only give the proof of (ii) below, making this choice because in this work we are mainly concerned with \( C^{\frac{k}{\tau}+\alpha} \) asymptotically flat manifolds.

Following the proof of [CZ15, Theorem 5.4], we first use a scaling argument on annuli along with the Schauder estimates for parabolic equations as in [Lie96],...
as $R$ sufficiently large we obtain by combining (A.5), (A.6), and (A.7) that

$$\|v\|_{C^{k+\alpha, (k+\alpha)/2}_r(E_R \times [0,T])} \leq C\left(\|\partial_t - \Delta_0\|v\|_{C^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} + \|v\|_{C^{0,\alpha}_r(E_R \times [0,T])}\right), \quad (A.5)$$

for $R > R_0$, where $R_0 > 0$ is as in Definition 2.1 and $E_R = \Phi^{-1}(\mathbb{R}^n \setminus B_R(0)) \subset M$. Here $\Delta_0$ denotes the Laplacian with respect to the flat metric defined by $\Phi$ on $E_R$. Define the operator

$$P = h(\Delta_0 - a(n)R_0) = h(g_0^{ij} \frac{\partial^2}{\partial x^i \partial x^j} + b^j \frac{\partial}{\partial x^j} - a(n)R_0),$$

where $h = \frac{1}{\sqrt{1-v_0^2}}$ and in the last expression above we have rewritten $\Delta_0$ in terms of the Euclidean coordinates given by $\Phi$. We then have

$$(\partial_t - P)v = a(n)R_0.$$

We will now compare $\partial_t - P$ on $E_R \times [0,T]$. Decompose $v = v_0 + v_\infty$ using a suitable cutoff function so that supp$(v_\infty) \subset E_R$; then with the help of the product inequality of Lemma [A.3] we can estimate

$$\|\Delta_0 - P\|v_\infty\|_{C^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} \leq \|h g_0^{ij} - \delta_{ij} \|_{C^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} \|D_x^2 v_\infty\|_{C^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} + \|h\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}(E_R \times [0,T])} \|b\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}(E_R \times [0,T])} \|D_x v_\infty\|_{C^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} + \|h\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}(E_R \times [0,T])} \|R_0\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} \|v_\infty\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} \|\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])}.$$

Moreover,

$$\|h g_0^{ij} - \delta_{ij}\|_{C^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} + \|b\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} \|R_0\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} \|v_\infty\|_{\mathcal{C}^{k-2+\alpha, (k-2+\alpha)/2}_r(E_R \times [0,T])} \rightarrow 0 \quad (A.6)$$

as $R \rightarrow \infty$ because of the asymptotic decay of $v$ and $g_0$. Thus, by taking $R$ sufficiently large we obtain by combining (A.5), (A.6), and (A.7) that

$$v_\infty\|_{C^{k+\alpha, (k+\alpha)/2}(\mathcal{M})} \leq C\left(\|\partial_t - P\|v_\infty\|_{C^{k-2+\alpha, (k-2+\alpha)/2}(\mathcal{M})} + \|v_\infty\|_{C^{0,\alpha}(\mathcal{M})}\right), \quad (A.8)$$

36
To deal with the first term on the right, if we let $\zeta_R$ be a suitably chosen cutoff function so that $v_0 = \zeta_R v$, $v_{\infty} = (1-\zeta_R)v$, then we have

$$
\left\| (\partial_t - P)v_{\infty} \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}} \leq \left\| (\partial_t - P)v \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}} + \left\| (\partial_t - P)(\zeta_R v) \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}} + 2\left\| (\partial_t - P)v \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}} \\
+ C_R \left\| v + |\nabla g_0 v| \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}_0((E_R \setminus E_{2R}) \times [0,T])}.
$$

(A.9)

We leave this for now and turn to consider $v_0$. On the bounded space-time domain $\text{supp}(v_0) \subset M$ we can directly apply the Schauder estimates for parabolic equations as in [Lie90, Theorem 4.9], to obtain, similarly to (A.8),

$$
\left\| v_0 \right\|_{C^{k+\alpha,(k+\alpha)/2}_0(M)} \leq C\left( \left\| (\partial_t - P)v_0 \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}_0(M)} + \left\| v_0 \right\|_{C^{0+\alpha}_0(M)} \right),
$$

(A.10)

and similar to (A.9) we also have

$$
\left\| (\partial_t - P)v_0 \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}} \leq 2\left\| (\partial_t - P)v \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}} + C_R \left\| v + |\nabla g_0 v| \right\|_{C^{k-2+\alpha,(k-2+\alpha)/2}_0((E_R \setminus E_{2R}) \times [0,T])}.
$$

(A.11)

Finally, putting (A.8), (A.9), (A.10), and (A.11) together, applying a Hölder norm interpolation inequality to deal with the $|\nabla g_0 v|$ terms, and recalling that $(\partial_t - P)v = a(n)R_{g_0}$, we obtain the desired estimate (A.4).

We are now in a position to prove Theorem 2.6.

**Proof of Theorem 2.6.** The case $k = 2$ is proved in [CZ15, Theorem 1.3]. So we need only concern ourselves with $k \geq 3$, and by induction we may assume that $\|v\|_{C^{k-2+\alpha,(k-2+\alpha)/2}}$ is bounded on $M$.

Clearly by our hypotheses $v$ is bounded in $C^{k-2+\alpha,(k-2+\alpha)/2}_0(M)$. And since $(M^n, g_0)$ is $C^{k+\alpha}_\tau$ asymptotically flat, we also have $R_{g_0} \in C^{k-2+\alpha,(k-2+\alpha)/2}_\tau(M)$. Proposition 3.5 therefore implies that $v \in C^{k+\alpha}_\tau$ for all $t \in [0,T]$ as desired.

\[\square\]

**B $C^{k+\alpha}_\tau$ conformal deformations**

We will indicate here how the statements Propositions 3.1 and 3.2 on conformal deformations of AF manifolds with metrics lying in weighted Hölder spaces follow from the the corresponding results given in [CB81, Max05, DM15], which work with weighted Sobolev spaces. We begin by recalling those results.

Corresponding to Proposition 5.1 we have:

37
**Proposition B.1** ([DM18, Lemma 4.3]). Let \((M^n, g)\) be a \(W_{-\tau}^{k,p}\) AF manifold with \(k \geq 2\), \(k > \frac{n}{2}\), and \(\tau \in (0, n - 2)\). Suppose \(R' \in W_{-\tau}^{k-2,p}\) satisfies \(R' \leq R_g\). Then there exists a positive function \(\phi\) with \(\phi - 1 \in W_{-\tau}^{k,p}\) such that the scalar curvature of \(g' = \phi^{n-2}g\) is \(R'\). In particular \(g'\) is also a \(W_{-\tau}^{k,p}\) AF metric.

Corresponding to Proposition [A.2] we have:

**Proposition B.2** ([DM18, Proposition 3]). Let \((M^n, g)\) be a \(W_{-\tau}^{k,p}\) AF manifold with \(k \geq 2\), \(k > \frac{n}{2}\), and \(\tau \in (0, n - 2)\). Then the following are equivalent:

1. We have \(Y(M, [g]) > 0\).
2. There exists a positive function \(\phi\) with \(\phi - 1 \in W_{-\tau}^{k,p}\) such that \(\tilde{g} = \phi^{n-2}g\) is conformally equivalent to \(g\) and \(R_{\tilde{g}} \equiv 0\).

We note that in [DM18], Proposition B.1 is actually stated in the \(W^{2,p}_{-\tau}\) setting, but the proof uses the \(W^{k,p}_{-\tau}\) results established earlier in [DM18], and the more general \(W^{k,p}_{-\tau}\) statement given above follows by the same argument.

Now starting from the hypotheses of Propositions B.1 and B.2, we first observe that \(C_{-\tau}^{k+\alpha} \hookrightarrow W_{-\tau}^{k,p}\) for any \(p < \infty\) if \(\tau' < \tau\). Therefore Propositions A.1 and A.2 immediately give us the existence of metrics \(g'\) and \(\tilde{g}\) belonging to \(W_{-\tau}^{k,p}\), and we just need to establish that they additionally belong to \(C_{-\tau}^{k+\alpha}\). Moreover, by taking \(p\) sufficiently large we have \(W_{-\tau}^{k,p} \hookrightarrow C_{-\tau}^{\alpha}\), for any \(\tau' < \tau\). We can then conclude the results of both Propositions B.1 and B.2 by proving a regularity estimate arising from this information. Indeed, this is essentially an application of the elliptic theory of weighted Hölder spaces on punctured regions of \(\mathbb{R}^n\) as for instance in [PR00].

**Lemma B.3.** Let \((M^n, g)\) be a \(C_{-\tau}^{k+\alpha}\) AF manifold, \(k \geq 2\), with \(\tau \in (0, n - 2)\). If \(R \in C_{-\tau}^{k-2+\alpha}\) and \(\phi \in C_{-\tau}^{k+\alpha}\) for all \(\tau' < \tau\) satisfy

\[
-a(n)\Delta_g \phi + R_g \phi = R\phi^N, \tag{B.1}
\]

then \(\phi - 1 \in C_{-\tau}^{k+\alpha}\).

**Proof.** Let \(\psi = \phi - 1\). Elliptic weighted Schauder estimates can be derived by scaling on annuli as in the proof of Proposition A.3 (essentially the same procedure as in [CZ15, Bar86]), which when applied to (B.1) then imply

\[
\|\psi\|_{C_{-\tau'}^{k+\alpha}} \leq C \left(\|R_g\|_{C_{-\tau'}^{k-2+\alpha}} + \|R\|_{C_{-\tau'}^{k-2+\alpha}} + \|\psi\|_{C_{-\tau'}^{0}}\right).
\]

Above we have used the product inequalities of Proposition A.3 along with \(\psi \in C_0^0\) in order to deal with the multiplications of \(R_g\) and \(R\) against powers of \(\psi\). The same estimate would then show us that \(\psi \in C_{-\tau}^{k+\alpha}\) once we establish that \(\psi \in C_{-\tau}^{0}\), and we shall now do so.
For ease of notation we assume that we have asymptotic coordinates \( \Phi : M \setminus K \to \mathbb{R}^n \setminus B_1(0) \). Then we can rewrite (B.1) in the Euclidean coordinates as

\[
-\Delta_0 \psi + (\delta^{ij} - g^{ij}) D^2_{ij} \psi + b^i D_i \psi + R_g(1 + \psi) = R(1 + \psi)^N
\]

where \( \Delta_0 \) is the Euclidean Laplacian and \( -\Delta_g = -g^{ij} D^2_{ij} + b^i D_i \). Using that \( g \in C^{k+\alpha}_{2-n}, D^2 \psi \in C^{2-k-\alpha}_{2-n}, D \psi \in C^{1-k-\alpha}_{2-n}, \) and \( R \in C^{k-2+\alpha}_{2-n} \), all together with the product inequality from Proposition 3, we see that (B.2) takes the form

\[
-\Delta_0 \psi = f \in C^{0+\alpha}_{2-n}, \quad \text{on } \mathbb{R}^n \setminus B_1(0).
\]

We now apply the Kelvin transform from \( \mathbb{R}^n \setminus B_1(0) \) to \( \overline{B_1(0)} \}. \) Following the definitions in [PR00], we will denote weighted spaces on \( \mathbb{R} \setminus B_1(0) \) by for instance \( C^{k+\alpha}_{2-n} \), in order to distinguish them from weighted spaces on \( \mathbb{R}^n \setminus B_1(0) \), which we will still denote by \( C^{k+\alpha}_{2-n} \). We will similarly denote the Kelvin transform of \( \psi \) by \( \psi^* : \overline{B_1(0)} \} \to \mathbb{R} \), and similarly for other functions.

It is then possible to check that \( \psi \in C^{k+\alpha}_{2-n} \) implies \( \psi^* \in C^{k+\alpha}_{2-n} \). In particular, since \( \tau \in (0, n-2) \) we also have \( 2 + n - \tau \in (0, n-2) \), and therefore by [PR00] Proposition 2.4, \( \Delta_0 : C^{2+\alpha}_{2-n+\tau,D} \to C^{\alpha}_{2-n+\tau-2} \) is invertible for all \( \tau \in (0, n-2) \). Here \( C^{2+\alpha}_{2-n+\tau,D} \) means those functions of \( C^{2+\alpha}_{2-n+\tau} \) which vanish on \( \partial B_1(0) \). Thus, since we already know that \( \psi \in C^{k+\alpha}_{2-n} \) for any \( \tau' < \tau \), we see that \( \psi^* \in C^{2+\alpha}_{2-n+\tau'} \) and

\[
-\Delta_0 \psi^* = |x^*|^{-4} f^* \in C^{\alpha}_{2-n+\tau'-2},
\]

while using (B.3) and [PR00] Proposition 2.4, there exists a \( w^* \in C^{2+\alpha}_{2-n+\tau,D} \)

solving

\[
-\Delta_0 w^* = |x^*|^{-4} f^* \in C^{\alpha}_{2-n+\tau-2}.
\]

Hence \( \psi^* - w \in C^{2+\alpha}_{2-n+\tau} \) must be harmonic in the entire ball \( B_1(0) \) since the order \( 2+n+\tau' > 2-n \) implies the singularity at zero can be removed. Thus we see that \( \psi^* \in C^{2+\alpha}_{2-n+\tau} \) implies \( C^{0}_{2-n+\tau} \), as well, and transforming back to \( \mathbb{R} \setminus B_1(0) \) we obtain as desired that \( \psi \in C^{0}_{n-\tau} \). \( \square \)

C \( L^p \) control of \( R \) for small \( p \)

Here we address regularity issue that might potentially arise in proving Lemma 4.3 and show that they do not pose any problems.

We first look at a lemma about auxiliary function \( w \) constructed in order to deal with the set the scalar curvature vanishes \( \{ x \in M^n, R(x,t) = 0 \} \) at time \( t \).

Lemma C.1. There exists a solution \( w \) to \( \partial_t w = (n-1) \Delta w + Rw \) with the appropriate spatial decay \( w(x,0) \sim |x|^{-s} \) and \( \nabla w(x,0) \sim |x|^{-s-1} \) at the initial time and \( w(x,0) > 0 \) on \( M^n \), and \( w(x,t) > 0 \) for all \( x \in M^n, t > 0 \).
Proof of Lemma C.1. We have already got $L^\infty$ control of $R$ from the Moser iteration, so there exists $\lambda > \sup_{\mathbb{R}^n \times [0, \infty)} |R|$. By results of [CTY11] the fundamental solution $\Psi(x, t)$ to operator $\partial_t - (n - 1) \Delta - R$ exists, and satisfying heat kernel type estimate: Thus define

$$w(x, t) := \int_M \Psi(x - y, t) w(y, 0) dy$$

satisfying $\partial_t w = (n - 1) \Delta w + Rw$ with initial condition. We now want to show (1) $w(x, t) > 0$ if $w(x, 0) > 0$; and (2) $w(x, t)$ decays of order $s$ for all $0 < t < t_{\text{max}}$ if $w(x, 0)$ decays of order $s$. It is not hard to see $w$ satisfies conditions of the maximum principle Theorem 4.3 of Ecker and Huisken [EH91]. In fact, conditions (i), (ii), (iv) in Theorem 4.3 [EH91] are obvious. To show condition (iii) $\int_0^T \int_M \exp(-\alpha^2 r^4(p, y)^2) |\nabla w|^2(y) d\mu(y) dt < \infty$ for some $\alpha > 0$, we note that since $\nabla w(x, 0)$ decays, and thus $L^\infty$ on $M^n$, $\int_M \Psi(x - y, t) \nabla w(y, 0) d\mu(y)$ is $L^\infty$ on $M^n$. Thus

$$\int_M \exp(-\alpha^2 r^4(p, y)^2) |\nabla w|^2(y) d\mu(y) \leq \int_M \exp(-\alpha^2 r^4(p, y)^2) d\mu(y) < \infty.$$

To prove (2) $w(x, t)$ decays of order $s$ if $w(x, 0)$ decays of order $s$, we use the idea of Cheng-Zhu [CZ15], and consider the function $f(x, t) := h(x) w(x, t) - C$ where $h(x) := |x|^s$, and $C$ is a large enough constant so that $f(x, 0) \leq 0$ using the decay assumption of $w(x, 0)$. Then $f(x, t)$ satisfies an evolution equation in which its coefficients satisfy all the conditions of the maximum principle of Ecker-Huisken [EH91] that we used before. Thus $f(x, t) \leq 0$ as $f(x, 0) \leq 0$. This is to say

$$w(x, t) \leq \frac{C}{|x|^s}.$$

Note $|x|$ is equivalent to the distance function with respect metric $g(t)$, so

$$w(x, t) \leq \frac{C}{d_{g(t)}(x, 0)^s}.$$

This allows us to prove a version of Lemma 4.3 without needing to worry about regularity issues at points when $R = 0$. We can control $|R|$ from above by a positive function which satisfies the same decay estimates along with

$$\frac{\partial}{\partial t} A \leq (n - 1) \Delta A + RA,$$

so we can carry out our estimates on $A$ instead.

Proof of Lemma 4.3. Now we can run the rest of the argument to control $L^p$ norms of $R$ when $p < \frac{n}{2}$. Let $A^2 := R^2 + w^2$; $\partial_t w = (n - 1) \Delta w + Rw$. By the above explanation, $w > 0$. Hence $A > 0$. 

40
Note that $w^2$ satisfies $\partial_t w^2 = (n-1)\Delta(w^2) - 2(n-1)|\nabla w|^2 + 2Rw^2$. We set the initial condition on $u$ so that it has the same asymptotic decay rate as $R$, i.e. $w \sim e^{r_{-2-\tau}}$. Then by Cauchy-Schwarz
\[ |\nabla(R^2 + w^2)|^2 \leq 4(|R|^2 + w^2)(|\nabla R|^2 + |\nabla w|^2). \]
Thus $A^2 = R^2 + w^2$ satisfies the evolution inequality
\[ \partial_t A^2 \leq (n-1)\Delta A^2 - \frac{n-1}{2} |\nabla A|^2 + 2RA^2 \]
and therefore (since we have the strict inequality $A > 0$),
\[ \partial_t A \leq (n-1)\Delta A + RA. \]
The evolution inequality $A$ satisfies is exactly the form of inequality satisfied by $R$, except now we know that $A > |R| \geq 0$. Thus for any $p$ such that $\int A^p \, dv_t$ is integrable (in particular $p < \frac{n}{2}$ but close to $\frac{n}{2}$)
\[ \frac{d}{dt} \int A^p \, dv_t \leq \int pA^{p-1} \partial_t A - \frac{n}{2} RA^p \, dv_t. \]
Hence
\[ \frac{d}{dt} \int A^p \, dv_t \leq \int pA^{p-1}(n-1)\Delta A + RA - \frac{n}{2} RA^p \, dv_t, \]
and
\[ \frac{d}{dt} \int A^p \, dv_t \leq -p(n-1)(p-1) \int A^{p-2} |\nabla A|^2 \, dv_t + (p - \frac{n}{2}) \int RA^p \, dv_t. \]
(C.1)
Note $n \geq 3$ implies for $p < \frac{n}{2}$ but close to $\frac{n}{2}$, $p-1 > 0$. So the first term on the right has a negative sign. In the meanwhile recall for the second term that
\[ \left| \left( p - \frac{n}{2} \right) \int RA^p \right| \leq \left| p - \frac{n}{2} \right| \|R\|_{L^n_{1/2}} \left( \int A^{p-\frac{n}{2}} \, dv_t \right)^{\frac{n-2}{n}}. \]
(C.2)
Since we have proved $\|R\|_{L^n_{1/2}}$ is monotonic decreasing, it is bounded depending only on $g_0$, so for $p < \frac{n}{2}$ but very close to $\frac{n}{2}$ this second term can be absorbed by the gradient term, using the Sobolev inequality. Therefore we see as desired that for such $p$,
\[ \frac{d}{dt} \int A^p \, dv_t \leq 0. \]
