SEMIDIRECT PRODUCTS OF REPRESENTATIONS UP TO HOMOTOPY

Yunhe Sheng and Chenchang Zhu

We study the semidirect product of a Lie algebra with a representation up to homotopy and provide various examples coming from Courant algebroids, Lie 2-algebras of string type, and omni-Lie algebroids. In the end, we study the semidirect product of a Lie group with a representation up to homotopy and use it to give an integration of a certain Lie 2-algebra of string type.

1. Introduction

This paper is the first part of our project to integrate representations up to homotopy of Lie algebras (algebroids). Our original motivation is to integrate the standard Courant algebroid $T M \oplus T^* M$, since it is this Courant algebroid that is much used in Hitchin and Gualtieri’s program of generalized complex geometry. Courant algebroids are Lie 2-algebroids in the sense of Roytenberg [2002] and Ševera [2005]. The general procedure to integrate Lie $n$-algebras (algebroids) is already described in [Getzler 2009; Henriques 2008; Ševera 2005]. We want to pursue some explicit formulas for the special case of the standard Courant algebroid. It turns out that the sections of the Courant algebroid $T M \oplus T^* M$ form a semidirect product of a Lie algebra with a representation up to homotopy. Abad and Crainic [2009] recently studied the representations up to homotopy of Lie algebras, Lie groups, and even Lie algebroids, Lie groupoids, in general. Just as one can form the semidirect product of a Lie algebra with a representation, one can form the semidirect product with representations up to homotopy too. In our case, the semidirect product coming from the standard Courant algebra is a Lie 2-algebra. But using the fact that it is also a semidirect product, the integration becomes easier. The integration result is related to the semidirect product of Lie groups with its representation up to homotopy, as will be discussed in Section 3. However it turns out that Abad

and Crainic’s concept of representations up to homotopy of Lie groups will not be general enough to cover all the integration results. This we will continue in a forthcoming paper [Sheng and Zhu 2010].

In this paper we focus on exhibiting more examples of representations up to homotopy and their semidirect products in order to demonstrate the importance of our integration procedure. The examples are all variations of Courant algebroids. One is Chen and Liu’s omni-Lie algebroids, which generalize Weinstein’s omni-Lie algebras. Hence we expect in [Sheng and Zhu 2010] to give an integration to Weinstein’s omni-Lie algebras via Lie 2-algebras.

Another example comes from a more general string Lie 2-algebra, which we call the \textit{Lie 2-algebra of string type}. It is essentially a Courant algebroid over a point (see Example II), namely a Lie algebra with an adjoint-invariant inner product. This sort of Lie algebra is usually called a \textit{quadratic Lie algebra}. This concept also appears in the context of Manin triples and double Lie algebras. The example $\mathbb{R} \to \mathfrak{g} \oplus \mathfrak{g}^*$ that we consider in this paper is an analogue of the standard Courant algebroid, and is basically a special case taken from [Lu and Weinstein 1990].\footnote{private conversation with Jiang-Hua Lu} We give an integration of the Lie 2-algebra of string type $\mathbb{R} \to \mathfrak{g} \oplus \mathfrak{g}^*$ at the end.

Usually people require the base Lie algebra of a string Lie 2-algebra to be semisimple and of compact type (see Remark 2.11). For such string Lie 2-algebras, Baez and Lauda [2004] have proved a no-go theorem: such string Lie 2-algebras cannot be integrated to finite-dimensional semistrict Lie 2-groups. Here a \textit{semistrict Lie 2-group} is a group object in DiffCat, where DiffCat is the 2-category consisting of categories, functors, and natural transformations in the category of differential manifolds, or equivalently DiffCat is a 2-category with Lie groupoids as objects, strict morphisms of Lie groupoids as morphisms, and 2-morphisms of Lie groupoids as 2-morphisms. Our semistrict Lie 2-group is actually called a Lie 2-group by Baez and Lauda. However, we call it a semistrict Lie 2-group because compared to the Lie 2-group in the sense of Henriques [2008], or equivalently (the equivalency was proved in [Zhu 2009]) the stacky group in the sense of Blohmann [2008], it is stricter. Basically, their Lie 2-group is a group object in the 2-category with objects as Lie groupoids, morphisms as Hilsum–Skandalis bimodules (or generalized morphisms), 2-morphisms as 2-morphisms of Lie groupoids. Schommer-Pries [2010] realizes the string 2-group as such a Lie 2-group with a finite-dimensional model; the integration of a string Lie 2-algebra to such a model is work in progress [Schommer-Pries et al. ≥ 2011].

It is not needed in the definition of the string Lie 2-algebra for the base Lie algebra to be semisimple of compact type. One only needs a quadratic Lie algebra. As soon as we relax this condition, we find out that one can integrate $\mathbb{R} \to \mathfrak{g} \oplus \mathfrak{g}^*$
to a finite dimensional semistrict Lie 2-group in the sense of Baez and Lauda. The integrating object is actually a special Lie 2-group (very close to a strict Lie 2-group) in the sense of Baez and Lauda.

Of course, as we relax the condition, we are in danger that the class corresponding to this Lie 2-algebra in $H^3(g \oplus g^*, \mathbb{R})$ might be trivial, and consequently our Lie 2-algebra might be trivially strictified. Then what we have done would not have been a big surprise because a strict Lie 2-algebra corresponds to a crossed module of Lie algebras, and it easily integrates to a strict Lie 2-group by integrating the crossed module. However, we verify that when $g$ itself (not $g \oplus g^*$) is semisimple, this class is not trivial.

2. Representations up to homotopy of Lie algebras

Here, we first consider the 2-term representation up to homotopy of Lie algebras. We give explicit formulas of the corresponding 2-term $L_\infty$-algebra, which is their semidirect product. Then we give several interesting examples including Courant algebroids and omni-Lie algebroids.

2a. Representations up to homotopy of Lie algebras and their semidirect products. $L_\infty$-algebras, sometimes called strongly homotopy Lie algebras, were introduced by Drinfeld and Stasheff [Stasheff 1992] as a model for “Lie algebras that satisfy Jacobi identity up to all higher homotopies”. The following convention of $L_\infty$-algebras has the same grading as in [Henriques 2008] and [Roytenberg and Weinstein 1998].

**Definition 2.1.** An $L_\infty$-algebra is a graded vector space $L = L_0 \oplus L_1 \oplus \cdots$ equipped with a system $\{l_k | 1 \leq k < \infty\}$ of linear maps $l_k : \bigwedge^k L \to L$ with degree $\deg(l_k) = k - 2$, where the exterior powers are interpreted in the graded sense and the sum

$$\sum_{i+j=n+1} (-1)^{i(j-1)} \sum_{\sigma} \text{sgn}(\sigma) K\text{sgn}(\sigma) l_i(l_j(x_{\sigma(1)}, \ldots, x_{\sigma(i)}), x_{\sigma(i+1)}, \ldots, x_{\sigma(n)})$$

vanishes for all $n \geq 0$, where $K\text{sgn}$ is the Koszul sign and the sum is taken over all $(i, n-i)$-unshuffles with $i \geq 1$.

Letting $n = 1$, we have

$$l_1^2 = 0, \quad l_1 : L_{i+1} \to L_i,$$

which means that $L$ is a complex; we usually write $d = l_1$. Letting $n = 2$, we have

$$dl_2(x, y) = l_2(dx, y) + (-1)^pl_2(x, dy) \quad \text{for all } x \in L_p, y \in L_q,$$

which means that $d$ is a derivation with respect to $l_2$. We usually view $l_2$ as a bracket $[\cdot, \cdot]$. However, it is not a Lie bracket: the obstruction of the Jacobi
identity is controlled by $l_3$:

\begin{equation}
(1) \quad l_2(l_2(x, y), z) + (-1)^{(p+q)r}l_2(l_2(y, z), x) + (-1)^{q+1}l_2(l_2(x, z), y)
= -d_3(x, y, z) - l_3(dx, y, z) + (-1)^{pq}l_3(dy, x, z) - (-1)^{(p+q)r}l_3(dz, x, y),
\end{equation}

where $x \in L_p$, $y \in L_q$, $z \in L_q$ and $l_3$ also satisfies higher coherence laws.

In particular, if the $k$-th brackets are zero for all $k > 2$, we recover the usual notion of differential graded Lie algebras (DGLA). If $L$ is concentrated in degrees less than $n$, then $L$ is called an $n$-term $L_\infty$-algebra.

In this paper, we mainly consider 2-term $L_\infty$-algebras, which are equivalent to the Lie 2-algebras given by John Baez and Alissa Crans [2004]. In this special case, $l_4$ is always zero. Thus by restricting the coherence law satisfied by $l_3$ on degree 0, we obtain

\begin{equation}
(2) \quad l_3(l_2(x, y), z, w) + \text{c.p.} - (l_2(l_3(x, y, z), w) + \text{c.p.}) = 0
\end{equation}

for all $x, y, z, w \in L_0$,

where c.p. stands for cyclic permutation. Lie 2-algebras are categorified versions of Lie algebras. In a Lie 2-algebra, the Jacobi identity is replaced by an isomorphism called the Jacobiator. The Jacobiator satisfies a certain law of its own. Given a 2-term $L_\infty$-algebra $L_1 \xrightarrow{d} L_0$, the underlying 2-vector space of the corresponding Lie 2-algebra is made up by $L_0$ as the vector space of objects and $L_0 \oplus L_1$ as the vector space of morphisms. See [Baez and Crans 2004, Theorem 4.3.6] for details.

Recall from [Baez and Crans 2004] that a Lie 2-algebra is skeletal if isomorphic objects are equal. Viewing a Lie 2-algebra as a 2-term $L_\infty$-algebra, explicitly we have this:

**Definition 2.2.** A 2-term $L_\infty$-algebra $L_1 \xrightarrow{d} L_0$ is called skeletal if $d = 0$.

**Theorem 2.3** [Baez and Crans 2004]. There is a bijection between 2-term skeletal $L_\infty$-algebra $L_1 \xrightarrow{d} L_0$ and quadruples $(\mathfrak{k}_1, \mathfrak{k}_2, \phi, \theta)$, where $\mathfrak{k}_1$ is a Lie algebra, $\mathfrak{k}_2$ is a vector space, $\phi$ is a representation of $\mathfrak{k}_1$ on $\mathfrak{k}_2$, and $\theta$ is a 3-cocycle on $\mathfrak{k}_1$ with values in $\mathfrak{k}_2$.

Given a 2-term skeletal $L_\infty$-algebra $L_1 \xrightarrow{d} L_0$, recall that $\mathfrak{k}_1$ is $L_0$, $\mathfrak{k}_2$ is $L_1$, the representation $\phi$ comes from $l_2$, and the 3-cocycle $\theta$ is obtained from $l_3$.

See [Abad and Crainic 2009; Abad 2008] for the general theory of representation up to homotopy of Lie algebroids. In this paper we only consider the 2-term representations up to homotopy of Lie algebras.

**Definition 2.4** [Abad and Crainic 2009]. A 2-term representation up to homotopy of a Lie algebra $\mathfrak{g}$ consists of the following:

\begin{itemize}
  \item[(i)] A 2-term complex of vector spaces $V_1 \xrightarrow{d} V_0$.
\end{itemize}
(ii) Two linear maps \( \mu_i : \mathfrak{g} \rightarrow \text{End}(V_i) \) that are compatible with \( d \). That is, for any \( X \in \mathfrak{g} \) and \( \xi \in V_i \), we have

\[
(3) \quad d \circ \mu_1(X)(\xi) = \mu_0(X) \circ d(\xi).
\]

(iii) A linear map \( \nu : \bigwedge^2 \mathfrak{g} \rightarrow \text{Hom}(V_0, V_1) \) such that

\[
(4) \quad \mu_0[X_1, X_2] - [\mu_0(X_1), \mu_0(X_2)] = d \circ \nu(X_1, X_2),
\]

\[
(5) \quad \mu_1[X_1, X_2] - [\mu_1(X_1), \mu_1(X_2)] = \nu(X_1, X_2) \circ d,
\]

and

\[
(6) \quad [\mu_0(X_1) + \mu_1(X_1), \nu(X_2, X_3)] + \text{c.p.} = \nu([X_1, X_2], X_3) + \text{c.p.}
\]

We usually write \( \mu = \mu_0 + \mu_1 \) and denote a 2-term representation up to homotopy of a Lie algebra \( \mathfrak{g} \) by \( (V_1 \xrightarrow{d} V_0, \mu, \nu) \).

In [2009, Example 3.25], Abad and Crainic proved that one can associate to any representation up to homotopy \( V_\bullet \) of a Lie algebra \( \mathfrak{g} \) a new \( L_\infty \)-algebra \( \mathfrak{g} \ltimes V_\bullet \), which is their semidirect product. Here we make this construction explicit in the 2-term case.

Let \( (V_1 \xrightarrow{d} V_0, \mu, \nu) \) be a 2-term representation up to homotopy of \( \mathfrak{g} \). Then we can form a new 2-term complex

\[
(\mathfrak{g} \ltimes V_\bullet, d) : V_1 \xrightarrow{d} (\mathfrak{g} \oplus V_0).
\]

Define \( l_2 : \bigwedge^2 (\mathfrak{g} \ltimes V_\bullet) \rightarrow \mathfrak{g} \ltimes V_\bullet \) by setting

\[
l_2(X + \xi, Y + \eta) = [X, Y] + \mu_0(X)(\eta) - \mu_0(Y)(\xi),
\]

\[
l_2(X + \xi, f) = \mu_1(X)(f),
\]

\[
l_2(f, g) = 0
\]

for any \( X + \xi, Y + \eta \in \mathfrak{g} \oplus V_0 \) and \( f, g \in V_1 \). Note that \( l_2 \) is not a Lie bracket, but instead

\[
l_2(l_2(X + \xi, Y + \eta), Z + \gamma) + \text{c.p.} = d(\nu(X, Y)(\gamma)) + \text{c.p.}
\]

Define \( l_3 : \bigwedge^3 (\mathfrak{g} \ltimes V_\bullet) \rightarrow \mathfrak{g} \ltimes V_\bullet \) by setting

\[
l_3(X + \xi, Y + \eta, Z + \gamma) = -\nu(X, Y)(\gamma) + \text{c.p.}
\]

Then:

**Proposition 2.5.** With the notations above, if \( (V_1 \xrightarrow{d} V_0, \mu, \nu) \) is a 2-term representation up to homotopy of a Lie algebra \( \mathfrak{g} \), then \( (V_1 \xrightarrow{d} (\mathfrak{g} \oplus V_0), l_2, l_3) \) is a 2-term \( L_\infty \)-algebra.
Example I (Courant algebroids $TM \oplus T^*M$). Courant algebroids, introduced in [Liu et al. 1997] to study the double of Lie bialgebroids, each consist of a vector bundle $E \to M$ equipped with a nondegenerate symmetric bilinear form $\langle \cdot, \cdot \rangle$ on the bundle, an antisymmetric bracket $\langle \cdot, \cdot \rangle$ on the section space $\Gamma(E)$ and a bundle map $\rho: E \to TM$ such that a set of axioms are satisfied. One can be viewed as a Lie 2-algebroid with a “degree-2 symplectic form” [Roytenberg 2002]. The first example is the standard Courant algebroid $(\mathcal{T} = TM \oplus T^*M, \langle \cdot, \cdot \rangle, [\cdot, \cdot], \rho)$ associated to a manifold $M$, where $\rho: \mathcal{T} \to TM$ is the projection, the canonical pairing $\langle \cdot, \cdot \rangle$ is given by

$$\langle X + \xi, Y + \eta \rangle = \frac{1}{2}(\xi(Y) + \eta(X))$$ for all $X, Y \in \mathfrak{X}(M)$, $\xi, \eta \in \Omega^1(M)$, \hspace{1cm} (9)

and the antisymmetric bracket $[\cdot, \cdot]$ is given by

$$[X + \xi, Y + \eta] = [X, Y] + LX\eta - LY\xi + \frac{1}{2}d(\xi(Y) - \eta(X))$$ for all $X + \xi$, $Y + \eta \in \Gamma(\mathcal{T})$. \hspace{1cm} (10)

This is not a Lie bracket, but we have

$$[\lbrack e_1, e_2 \rbrack, e_3] + \text{c.p.} = dT(e_1, e_2, e_3)$$ for all $e_1, e_2, e_3 \in \Gamma(\mathcal{T})$, \hspace{1cm} (11)

where $T(e_1, e_2, e_3)$ is given by

$$T(e_1, e_2, e_3) = \frac{1}{3}(\lbrack \lbrack e_1, e_2 \rbrack, e_3 \rbrack + \text{c.p.}).$$ \hspace{1cm} (12)

Now we realize the section space of $\mathcal{T}$ as the semidirect product of the Lie algebra $\mathfrak{X}(M)$ of vector fields with the natural 2-term deRham complex

$$C^\infty(M) \xrightarrow{d} \Omega^1(M).$$ \hspace{1cm} (13)

For this we need to define a representation up to homotopy of $\mathfrak{X}(M)$ on this complex. For any $X \in \mathfrak{X}(M)$, define linear actions $\mu_0$ and $\mu_1$ by

$$\mu_0(X)(\xi) \triangleq \lbrack X, \xi \rbrack = LX\xi - \frac{1}{2}d(\xi(X))$$ for all $\xi \in \Omega^1(M)$, \hspace{1cm} (14)

$$\mu_1(X)(f) \triangleq \langle X, df \rangle = \frac{1}{2}X(f)$$ for all $f \in C^\infty(M)$. \hspace{1cm} (15)

Define $\nu: \wedge^2 \mathfrak{X}(M) \to \text{Hom}(\Omega^1(M), C^\infty(M))$ by

$$\nu(X, Y)(\xi) = T(X, Y, \xi)$$ for all $X, Y \in \mathfrak{X}(M)$, $\xi \in \Omega^1(M)$. \hspace{1cm} (16)

**Proposition 2.6.** With the above notations, $(C^\infty(M) \xrightarrow{d} \Omega^1(M), \mu = \mu_0 + \mu_1, \nu)$ is a representation up to homotopy of the Lie algebra $\mathfrak{X}(M)$.

**Proof.** For any $f \in C^\infty(M)$, we have

$$\mu_0(X)(df) = LXdf - \frac{1}{2}dX(f) = \frac{1}{2}dX(f),$$
which implies $\mu_0 \circ d = d \circ \mu_1$, that is, the $\mu_i$ are compatible with the differential $d$.

By straightforward computations, we have

$$
\mu_0[X, Y](\xi) - [\mu_0(X), \mu_0(Y)](\xi) = [[X, Y], \xi] + \text{c.p.}
$$

$$
= dT(X, Y, \xi) = d(\nu(X, Y)(\xi)),
$$

$$
\mu_1[X, Y](f) - [\mu_1(X), \mu_1(Y)](f) = \frac{1}{2}[X, Y](f) - \frac{1}{4}(X(Y(f)) - Y(X(f)))
$$

$$
= \frac{1}{4}[X, Y](f),
$$

$$
\nu(X, Y)(df) = T(X, Y, df) = \frac{1}{3}[X, Y](f) + \frac{1}{4}(X(Y(f)) - Y(X(f)))
$$

$$
= \frac{1}{4}[X, Y](f),
$$

which implies (4) and (5). At last we need to prove (6), which is obviously equivalent to

$$
\mu_1(X)T(Y, Z, \xi) - T(Y, Z, \mu_0(X)(\xi)) + \text{c.p.}(X, Y, Z)
$$

$$
= T([X, Y], Z, \xi) + \text{c.p.}(X, Y, Z).
$$

Observe that since $\mu_0(X)(\xi) = [[X, \xi]]$, we have

$$
T(Y, Z, \mu_0(X)(\xi)) + \text{c.p.}(X, Y, Z) + T([X, Y], Z, \xi) + \text{c.p.}(X, Y, Z)
$$

$$
= T([X, Y], Z, \xi) + \text{c.p.}(X, Y, Z, \xi).
$$

Furthermore, since $\mu_1(X)(f) = \langle X, df \rangle$ for any $f \in C^\infty(M)$ and the cotangent bundle $T^*M$ is isotropic under the pairing (9), we have

$$
\mu_1(X)T(Y, Z, \xi) + \text{c.p.}(X, Y, Z) = \langle X, dT(Y, Z, \xi) \rangle + \text{c.p.}(X, Y, Z, \xi).
$$

Thus, (17) is equivalent to

$$
\langle X, dT(Y, Z, \xi) \rangle + \text{c.p.}(X, Y, Z, \xi) = T([X, Y], Z, \xi) + \text{c.p.}(X, Y, Z, \xi),
$$

which holds by [Roytenberg and Weinstein 1998, Lemma 4.5].

By Proposition 2.5, we have this:

**Corollary 2.7.** $(C^\infty(M) \xrightarrow{d=0 \oplus d} \mathcal{X}(M) \oplus \Omega^1(M)), l_2, l_3)$ is a 2-term $L_\infty$-algebra, where $l_2$ and $l_3$ are given by (7) and (8), in which $\mu_0, \mu_1$ and $\nu$ are given by (14), (15) and (16), respectively.

**Remark 2.8.** Roytenberg and Weinstein [1998] have proved that the sections of a Courant algebroid $(\mathcal{E}, \langle \cdot, \cdot \rangle, [[\cdot, \cdot]], \rho)$ form an $L_\infty$-algebra. In the case when $\mathcal{E} = \mathcal{F}$ the standard Courant algebroid, the 2-term $L_\infty$-algebra is given by

$$
C^\infty(M) \xrightarrow{d=0 \oplus d} \mathcal{X}(M) \oplus \Omega^1(M) = \Gamma(\mathcal{F}),
$$
with brackets given by

\[ l_2(e_1, e_2) = [e_1, e_2], \quad l_2(e_1, f) = (e_1, df), \quad l_3(e_1, e_2, e_3) = -T(e_1, e_2, e_3), \]

and \( l_{i \geq 4} = 0 \) for any \( e_1, e_2, e_3 \in \Gamma(\mathcal{J}) \) and \( f \in C^\infty(M) \). Here \( T \) is defined by (12).

It is easy to verify that this is the same as our 2-term \( L_\infty \)-algebra in Corollary 2.7.

We can also modify our complex (13) to \( \Omega^1(M) \xrightarrow{\text{Id}} \Omega^1(M) \). Following the same procedure, we get another representation up to homotopy of the Lie algebra \( \mathfrak{X}(M) \) and therefore obtain another 2-term \( L_\infty \)-algebra that is also totally determined by the Courant algebroid \( (\mathcal{J}, \langle \cdot, \cdot \rangle, [[\cdot, \cdot]], \rho) \). More precisely, \( \mu_0 = \mu_1 \) is given by

\[ \mu_0(X)(\xi) \triangleq [[X, \xi]], \]

and \( \nu : \mathfrak{X}(M) \to \Omega^2(\mathfrak{X}^2(M), \text{End}(\Omega^1(M), \Omega^1(M))) \) is given by

\[ \nu(X, Y)(\xi) \triangleq dT(X, Y, \xi) \]

for any \( X, Y \in \mathfrak{X}(M) \) and \( \xi \in \Omega^1(M) \).

**Proposition 2.9.** With the above notations, \( (\Omega^1(M) \xrightarrow{\text{Id}} \Omega^1(M), \mu = \mu_0 = \mu_1, \nu) \) is a representation up to homotopy of the Lie algebra \( \mathfrak{X}(M) \).

**Example II** (Courant algebroids over a point and Lie 2-algebras of string type). A Courant algebroid over a point is literally a quadratic Lie algebra, namely a Lie algebra \( \mathfrak{k} \) together with nondegenerate inner product \( \langle \cdot, \cdot \rangle \) that is invariant under the adjoint action. People often think of a Courant algebroid over a point as a string Lie 2-algebra.\(^2\) Here we justify this thinking.

**Definition 2.10.** The Lie 2-algebra of string type associated to a quadratic Lie algebra \( (\mathfrak{k}, \langle \cdot, \cdot \rangle) \) is a 2-term \( L_\infty \)-algebra \( \mathbb{R} \xrightarrow{\theta} \mathfrak{k} \), whose degree-0 part is \( \mathfrak{k} \) and whose degree-1 part is \( \mathbb{R} \), with \( l_2, l_3 \) given by

\[ l_2((e_1, c_1), (e_2, c_2)) = ([e_1, e_2], 0), \]

\[ l_3((e_1, c_1), (e_2, c_2), (e_3, c_3)) = (0, ([e_1, e_2], e_3)), \]

where \( e_1, e_2, e_3 \in \mathfrak{k} \) and \( c_1, c_2, c_3 \in \mathbb{R} \).

The representation \( \phi \) of \( \mathfrak{k} \) on \( \mathbb{R} \) and the 3-cocycle \( \theta : \bigwedge^3 \mathfrak{k} \to \mathbb{R} \) in the corresponding quadruple in Theorem 2.3 is given by

\[ \rho(e)(c) = l_2(e, c), \]

(18) \[ \theta(e_1, e_2, e_3) = \langle [e_1, e_2], e_3 \rangle. \]

\(^2\)Private conversation with John Baez and Urs Schreiber.
Remark 2.11. In the definition of string Lie 2-algebras [Baez and Rogers 2010; Henriques 2008], the base Lie algebra \( \mathfrak{k} \) is usually required to be semisimple and of compact type, such that the Jacobiator gives rise to the generator of \( H^3(\mathfrak{k}, \mathbb{Z}) = \mathbb{Z} \). This is because Witten’s original motivation was to obtain a 3-connected cover of \( \text{Spin}(n) \), and \( \mathfrak{so}(n) \) is simple and of compact type. However, to write down the structure of the string Lie 2-algebra, we only need a quadratic Lie algebra. This is how we obtain the definition above on Lie 2-algebras of string type. Then \( H^3(\mathfrak{k}, \mathbb{Z}) \) is not necessarily \( \mathbb{Z} \) for a general quadratic Lie algebra \( \mathfrak{k} \). For example, for the abelian Lie algebra \( \mathbb{R} \), any inner product is adjoint-invariant, and \( H^3(\mathbb{R}, \mathbb{Z}) = 0 \). We thus face the danger that sometimes a Lie 2-algebra of string type might be trivial, that is, the Jacobiator might correspond to the trivial element in \( H^3(\mathfrak{k}, \mathbb{Z}) \). Then what we have can be trivially strictified to a strict Lie 2-algebra, which is a crossed module of Lie algebras. Then the integration of a crossed module of Lie algebras is simply a crossed module of Lie groups. However, we will verify that the example we consider is not such a case.

The standard Courant algebroid motivates us to consider the case of the direct sum \( \mathfrak{k} = \mathfrak{g} \oplus \mathfrak{g}^* \) of a Lie algebra \( \mathfrak{g} \) and its dual with the semidirect product Lie algebra structure:

\[
[X + \xi, Y + \eta] = [X, Y]_{\mathfrak{g}} + \text{ad}^*_{X} \eta - \text{ad}^*_{Y} \xi,
\]

where \([\cdot, \cdot]_{\mathfrak{g}}\) is the Lie bracket of \( \mathfrak{g} \). The nondegenerate invariant pairing \( \langle \cdot, \cdot \rangle \) on \( \mathfrak{g} \oplus \mathfrak{g}^* \) is given by

\[
\langle X + \xi, Y + \eta \rangle = \frac{1}{2} (\eta(X) + \xi(Y)) \quad \text{for all } X + \xi, Y + \eta \in \mathfrak{g} \oplus \mathfrak{g}^*.
\]

With these definitions, \( (\mathfrak{g} \oplus \mathfrak{g}^*, [\cdot, \cdot], \langle \cdot, \cdot \rangle) \) is a quadratic Lie algebra. In fact, we have

\[
\langle [X_1 + \xi_1, X_2 + \xi_2], X_3 + \xi_3 \rangle = \langle [X_1, X_2]_{\mathfrak{g}} + \text{ad}^*_{X_1} \xi_2 - \text{ad}^*_{X_2} \xi_1, X_3 + \xi_3 \rangle
\]

\[
= \langle [X_1, X_2]_{\mathfrak{g}}, \xi_3 \rangle + \text{c.p.}
\]

Similarly, we have

\[
\langle X_2 + \xi_2, [X_1 + \xi_1, X_3 + \xi_3] \rangle = \langle [X_1, X_3]_{\mathfrak{g}}, \xi_2 \rangle + \text{c.p.},
\]

which implies \( \langle X_2 + \xi_2, [X_1 + \xi_1, X_3 + \xi_3] \rangle + \langle [X_1 + \xi_1, X_2 + \xi_2], X_3 + \xi_3 \rangle = 0 \), that is, the nondegenerate inner product \( \langle \cdot, \cdot \rangle \) is invariant under the adjoint action. This example is a special case of [Lu and Weinstein 1990, Theorem 1.12] with \( \mathfrak{g}^* \) equipped with the 0 Lie bracket. Thus \( (\mathfrak{g}, \mathfrak{g}^*) \) forms a Lie bialgebra or equivalently \( (\mathfrak{g} \oplus \mathfrak{g}^*, \mathfrak{g}, \mathfrak{g}^*) \) is a Manin triple. However, honestly we have not found other Lie bialgebras (Manin triples) giving rise to Lie 2-algebras of the form of semidirect products.
We denote by
\[ (19) \quad \mathbb{R} \overset{0}{\to} g \oplus g^*, \]
the corresponding Lie 2-algebra of string type of \((g \oplus g^*, [\cdot, \cdot], \langle \cdot, \cdot \rangle)\). We denote by \(\tilde{\nu} : \bigwedge^3 (g \oplus g^*) \to \mathbb{R}\) the corresponding 3-cocycle (see (18))
\[ \tilde{\nu}(X_1 + \xi_1, X_2 + \xi_2, X_3 + \xi_3) = \langle [X_1 + \xi_1, X_2 + \xi_2], X_3 + \xi_3 \rangle = \langle [X_1, X_2]_g, \xi_3 \rangle + \text{c.p.} \tag{20} \]

**Proposition 2.12.** \((\mathbb{R} \overset{0}{\to} g^*, \mu_1 = 0, \mu_0 = \text{ad}^*, \nu = [\cdot, \cdot]_g)\) is a 2-term representation up to homotopy of the Lie algebra \(g\). Moreover the Lie 2-algebra of string type \(\mathbb{R} \overset{0}{\to} g \oplus g^*\) is the semidirect product of \(g\) with the complex \(\mathbb{R} \overset{0}{\to} g^*\).

**Proof.** Since \(d = 0\), we only need to verify that \(\mu_0\) and \(\mu_1\) are Lie algebra morphisms and (6). Both \(\text{ad}^* : g \to \text{End}(g^*)\) and 0 are Lie algebra morphisms, and (6) follows from Jacobi identity of \([\cdot, \cdot]_g\).

Then it is not hard to see that the Lie 2-algebra of string type \(\mathbb{R} \overset{0}{\to} g \oplus g^*\) with formulas in Definition 2.10 is exactly the semidirect product of \(g\) with the complex \((\mathbb{R} \overset{0}{\to} g^*, \mu_1 = 0, \mu_0 = \text{ad}^*, \nu = [\cdot, \cdot]_g)\) with the formulas (7) and (8). \(\square\)

**Proposition 2.13.** If the Lie algebra \(g\) is semisimple, the Lie algebra 3-cocycle \(\tilde{\nu}\) given by (20) is not exact.

**Proof.** Let \(\langle \cdot, \cdot \rangle_k\) be the Killing form on \(g\). The proof follows from the fact that the Cartan 3-form \(\langle [\cdot, \cdot], \cdot \rangle_k\) on a semisimple Lie algebra is not exact. Since \(g\) is semisimple, the Killing form \(\langle \cdot, \cdot \rangle_k\) is nondegenerate. Identify \(g^*\) and \(g\) by using the Killing form \(\langle \cdot, \cdot \rangle_k\) and let \(\mathcal{H}\) be the corresponding isomorphism,
\[ \langle \mathcal{H}(\xi), X \rangle_k = \langle \xi, X \rangle. \]

Assume that \(\tilde{\nu} = d\phi\) for some \(\phi : \bigwedge^2 (g \oplus g^*) \to \mathbb{R}\); define \(\varphi : \bigwedge^2 (g \oplus g) \to \mathbb{R}\) by
\[ \phi(X + \xi, Y + \eta) = \varphi(X + \mathcal{H}(\xi), Y + \mathcal{H}(\eta)). \]

Then we have
\[ \tilde{\nu}(X, Y, \xi) = d\phi(X, Y, \xi) \]
\[ = -\phi([X, Y], \xi) + \phi(\text{ad}_X^* \xi, Y) - \phi(\text{ad}_Y^* \xi, X) \]
\[ = -\varphi([X, Y], \mathcal{H}(\xi)) + \varphi([X, \mathcal{H}(\xi)], Y) - \varphi([Y, \mathcal{H}(\xi)], X) \]
\[ = d\varphi(X, Y, \mathcal{H}(\xi)). \]

On the other hand, we have
\[ \tilde{\nu}(X, Y, \xi) = \langle [X, Y], \xi \rangle = \langle [X, Y], \mathcal{H}(\xi) \rangle_k, \]
which implies that the Cartan 3-form
\[ \langle [X, Y], \mathcal{H}(\xi) \rangle_\xi = d\varphi(X, Y, \mathcal{H}(\xi)) \]
is exact. This is a contradiction. \( \square \)

In Section 4, we will give the integration of the Lie 2-algebra of string type \( \mathbb{R} \to g \oplus g^* \) by using the semidirect product of a Lie group with its 2-term representation up to homotopy. It turns out that this Lie 2-algebra of string type can be integrated to a special Lie 2-group with a finite-dimensional model.

**Example III** (Omni-Lie algebroids \( \mathcal{D}E \oplus \mathcal{J}E \)). Chen and Liu [2010] introduced omni-Lie algebroids to generalize Weinstein's omni-Lie algebras. Just as Dirac structures of an omni-Lie algebra characterize Lie algebra structures on a vector space, Dirac structures of an omni-Lie algebroid characterize Lie algebroid structures on a vector bundle. See [Chen et al. 2008] for more details. In fact, the role of the omni-Lie algebroids \( \mathcal{D}E \oplus \mathcal{J}E \) in \( E \)-Courant algebroids, which were introduced in [Chen et al. 2010], is the same as the role of standard Courant algebroids \( TM \oplus T^*M \) in Courant algebroids.

We briefly recall the notion of omni-Lie algebroids. We will see that it gives rise to a 2-term \( L_\infty \)-algebra that is a semidirect product. In this subsection \( E \) is a vector bundle over a smooth manifold \( M \), and \( \Gamma(E) \) is the section space of \( E \).

Let \( \mathcal{D}E \) be the covariant differential operator bundle of a vector bundle \( E \). The associated Atiyah sequence is given by
\[ 0 \to \mathfrak{gl}(E) \xrightarrow{i} \mathcal{D}E \xrightarrow{a} TM \to 0. \]  
We define the associated 1-jet vector bundle \( \mathcal{J}E \) as follows. For any \( m \in M \), we define \( (\mathcal{J}E)_m \) as a quotient of local sections of \( E \). Two local sections \( u_1 \) and \( u_2 \) are equivalent (we denote this by \( u_1 \sim u_2 \)) if
\[ u_1(m) = u_2(m) \quad \text{and} \quad d\langle u_1, \xi \rangle_m = d\langle u_2, \xi \rangle_m \quad \text{for all} \; \xi \in \Gamma(E^*). \]
So any \( \mu \in (\mathcal{J}E)_m \) has a representative \( u \in \Gamma(E) \) such that \( \mu = [u]_m \). Let \( \mathbb{P} \) be the projection that sends \( [u]_m \) to \( u(m) \). Then \( \ker \mathbb{P} \cong \text{Hom}(TM, E) \) and there is a short exact sequence
\[ 0 \to \text{Hom}(TM, E) \xrightarrow{\omega} \mathcal{J}E \xrightarrow{\mathbb{P}} E \to 0, \]  
called the jet sequence of \( E \). From this it is straightforward to see that \( \mathcal{J}E \) is a finite dimensional vector bundle. Also, \( \Gamma(\mathcal{J}E) \) is isomorphic to \( \Gamma(E) \oplus \Gamma(T^*M \otimes E) \) as an \( \mathbb{R} \)-vector space, and any \( u \in \Gamma(E) \) has a lift \( \mathbb{d}u \in \Gamma(\mathcal{J}E) \) by taking its equivalence class, such that
\[ \mathbb{d}(fu) = f \mathbb{d}u + df \otimes u \quad \text{for all} \; f \in C^\infty(M). \]
Chen and Liu [2010] proved that
\[ \mathfrak{J} E \cong \{ \nu \in \text{Hom}(\mathfrak{D} E, E) \mid \nu(\Phi) = \Phi \circ \nu(\text{Id}_E) \text{ for all } \Phi \in \mathfrak{gl}(E) \}. \]

Therefore, there is an $E$-pairing between $\mathfrak{J} E$ and $\mathfrak{D} E$ obtained by setting
\[ \langle \mu, \vartheta \rangle_E \triangleq \vartheta(u) \quad \text{for all } u \in \Gamma(E), \vartheta \in \mathfrak{D} E, \]
where $u \in \Gamma(E)$ satisfies $\mu = [u]_m$. Particularly, one has
\begin{align*}
    \langle \mu, \Phi \rangle_E &= \Phi \circ \rho_{\Phi}(\mu) \quad \text{for all } \Phi \in \mathfrak{gl}(E), \mu \in \mathfrak{J} E; \\
    \langle \eta, \vartheta \rangle_E &= \eta \circ a(\vartheta) \quad \text{for all } \eta \in \text{Hom}(TM, E), \vartheta \in \mathfrak{D} E.
\end{align*}

Furthermore, we claim that $\Gamma(\mathfrak{J} E)$ is an invariant subspace of the Lie derivative $\mathfrak{L}_\vartheta$ for any $\vartheta \in \Gamma(\mathfrak{D} E)$, which is defined by the Leibniz rule as follows:
\[ \langle \mathfrak{L}_{\vartheta} \mu, \vartheta' \rangle_E \triangleq \vartheta' \langle \mu, \vartheta \rangle_E - \langle \mu, [\vartheta, \vartheta']_\mathfrak{D} \rangle_E \quad \text{for all } \mu \in \Gamma(\mathfrak{J} E), \vartheta', \vartheta' \in \Gamma(\mathfrak{D} E). \]

Define a nondegenerate symmetric $E$-valued 2-form $\langle \cdot, \cdot \rangle$ on $\mathfrak{C} \triangleq \mathfrak{D} E \oplus \mathfrak{J} E$ by
\[ \langle \vartheta + \mu, \vartheta + \nu \rangle_E \triangleq \frac{1}{2}(\langle \vartheta, \vartheta \rangle_E + \langle \mu, \nu \rangle_E) \quad \text{for all } \vartheta, \nu \in \mathfrak{D} E, \mu, \nu \in \mathfrak{J} E. \]

Define an antisymmetric bracket $\llbracket \cdot, \cdot \rrbracket$ on $\Gamma(\mathfrak{C})$ by
\[ \llbracket \vartheta + \mu, \vartheta + \nu \rrbracket \triangleq \llbracket \vartheta, \vartheta \rrbracket_{\mathfrak{D}} + \mathfrak{L}_{\vartheta} \nu - \mathfrak{L}_{\vartheta} \mu + \frac{1}{2}(\text{cl} \langle \mu, \nu \rangle_E - \text{cl} \langle \nu, \vartheta \rangle_E). \]

Chen and Liu [2010] call the quadruple $(\mathfrak{C}, \llbracket \cdot, \cdot \rrbracket, \langle \cdot, \cdot \rangle, \rho_{\mathfrak{C}})$ the *omni-Lie algebroid* associated to the vector bundle $E$, where $\rho_{\mathfrak{C}}$ is the projection of $\mathfrak{C}$ onto $\mathfrak{D} E.$\(^3\) Even though $\llbracket \cdot, \cdot \rrbracket$ is antisymmetric, it is not a Lie bracket. More precisely, we have
\[ \llbracket \llbracket X, Y \rrbracket, Z \rrbracket + \text{c.p.} = \text{cl} T(X, Y, Z) \quad \text{for any } X, Y, Z \in \Gamma(\mathfrak{C}), \]
where $T : \Gamma(\wedge^3 \mathfrak{C}) \to \Gamma(E)$ is defined by
\[ T(X, Y, Z) = \frac{1}{2}(\llbracket \llbracket X, Y \rrbracket, Z \rrbracket_E + \text{c.p.}). \]

Let us construct a 2-term $L_\infty$-algebra from the omni-Lie algebroid $\mathfrak{C}$. Obviously, $\Gamma(\mathfrak{D} E)$ is a Lie algebra and there is a natural 2-term complex
\[ \Gamma(E) \xrightarrow{0 \oplus \text{Id}} \Gamma(\mathfrak{J} E). \]

For any $\vartheta \in \Gamma(\mathfrak{D} E)$, define linear actions $\mu_0$ and $\mu_1$ by
\begin{align*}
    \mu_0(\vartheta)(\mu) &\triangleq \llbracket \vartheta, \mu \rrbracket = \mathfrak{L}_{\vartheta} \mu - \text{cl} \langle \mu, \vartheta \rangle_E \quad \text{for all } \mu \in \Gamma(\mathfrak{J} E), \vartheta \in \Gamma(\mathfrak{D} E), \\
    \mu_1(\vartheta)(u) &\triangleq (\vartheta, \text{cl} u)_E = \frac{1}{2} \vartheta(u) \quad \text{for all } u \in \Gamma(E).
\end{align*}

\(^3\)This is slightly different from the notion given in [Chen and Liu 2010], where the bracket is not skew symmetric.
Define $\nu : \bigwedge^2 \Gamma(\mathcal{OE}) \to \text{Hom}(\Gamma(\mathcal{JE}), \Gamma(E))$ by

$$\nu(\partial, t)(\xi) = T(\partial, t, \mu) \quad \text{for all } \partial, t \in \Gamma(\mathcal{OE}), \mu \in \Gamma(\mathcal{JE}).$$

Similarly to Proposition 2.6, we prove:

**Proposition 2.14.** With the notations above, $\nu$ is a representation up to homotopy of the Lie algebra $\Gamma(\mathcal{OE})$.

**Corollary 2.15.** $\nu$ is a 2-term $L_\infty$-algebra, where $l_2$ and $l_3$ are given by (7) and (8), and $\mu$ and $\nu$ are given by (28) and (29), respectively.

**Remark 2.16.** If the base manifold $M$ is a point, that is, $E$ is a vector space, for which we use a new notation $V$, then $\mathcal{O}V = \text{gl}(V)$ and $\mathcal{J}V = V$, and we recover the notion of omni-Lie algebras. The complex $\Gamma(V) \to \Gamma(\mathcal{J}V)$ reduces to $V \to V$, which is a representation up to homotopy of $\text{gl}(V)$ with $\nu$ given by

$$\mu_0(A)(u) = \frac{1}{2}Au, \quad \nu(A, B) = \frac{1}{4}[A, B] \quad \text{for all } A, B \in \text{gl}(V), u \in V.$$

Hence even though an omni-Lie algebra $\text{gl}(V) \oplus V$ is not a Lie algebra, we can extend it to a 2-term $L_\infty$-algebra, of which $L_0 = \text{gl}(V) \oplus V$, $L_1 = V$, $l_2$ and $l_3$ are given by (7) and (8), in which $\mu$ and $\nu$ are given by (30). This 2-term $L_\infty$-algebra is a semidirect product of $\text{gl}(V)$ with $V \to V$.

We will study the global object of the 2-term $L_\infty$-algebra associated to an omni-Lie algebra in the forthcoming paper [Sheng and Zhu 2010].

### 3. Representations up to homotopy of Lie groups and semidirect products

The representation up to homotopy of a Lie group was introduced in [Abad 2008]. In this section we define the semidirect product of a Lie group with a 2-term representation up to homotopy and prove that the semidirect product is a Lie 2-group. Thus we first recall some background on Lie 2-groups.

A group is a monoid where every element has an inverse. A 2-group is a monoidal category where every object has a weak inverse and every morphism has an inverse. Denote the category of smooth manifolds and smooth maps by Diff, a semistrict Lie 2-group is a 2-group in DiffCat, where DiffCat is the 2-category consisting of categories, functors, and natural transformations in Diff. For more details, see [Baez and Lauda 2004]. Here we only recall the expanded definition:

**Definition 3.1** [Baez and Lauda 2004]. A semistrict Lie 2-group consists of an object $C$ in DiffCat, that is,

$$C_1 \xrightarrow{s} C_0,$$

where $s$ is the identity morphism on $C_0$. We call it a semistrict Lie 2-group.

---

4See the introduction for the reason we call it a semistrict Lie 2-group.
where $C_1$ and $C_0$ are objects in Diff, $s$ and $t$ are the source and target maps, and there is a vertical multiplication $\cdot_v : C \times C \to C$, together with

- a functor (horizontal multiplication) $\cdot_h : C \times C \to C$,
- an identity object 1,
- a contravariant functor $\text{inv} : C \to C$

and the following natural isomorphisms:

- the 
  associator $a_{x,y,z} : (x \cdot_h y) \cdot_h z \to x \cdot_h (y \cdot_h z)$,
- the left and right unit $l_x : 1 \cdot_h x \to x$ and $r_x : x \cdot_h 1 \to x$,
- the unit and counit $i_x : 1 \to x \cdot_h \text{inv}(x)$ and $e_x : \text{inv}(x) \cdot_h x \to 1$,

which are such that the following diagrams commute.

- The \textit{pentagon identity} for the associator:

- The \textit{triangle identity} for the left and right unit lows:

- The \textit{first zig-zag identity}:
• The second zig-zag identity:

\[
\begin{array}{c}
\text{inv}(x) \cdot_h 1 \\
\downarrow^{f_{\text{inv}(x)}} \\
\text{inv}(x)
\end{array}
\xrightarrow{d_{\text{inv}(x), x, \text{inv}(x)}}
\begin{array}{c}
\text{inv}(x) \cdot_h (x \cdot_h \text{inv}(x)) \\
\downarrow^{e_{x \cdot_h \text{inv}(x)}} \\
1 \cdot_h \text{inv}(x)
\end{array}
\]

In the special case where \(a_x, y, z, l_x, r_x, i_x\) and \(e_x\) are all identity isomorphisms, we call such a Lie 2-group a strict Lie 2-group.\(^5\)

**Definition 3.2** [Baez and Lauda 2004]. A special Lie 2-group is a Lie 2-group of which the source and target coincide and the left unit law \(l\), the right unit law \(r\), the unit \(i\) and the counit \(e\) are identity isomorphisms.

For classification of special Lie 2-groups, we need the group cohomology with smooth cocycles, that is, we consider the cochain complex with smooth morphisms \(G^n \rightarrow M\) with \(G\) a Lie group and \(M\) its module. The differential is defined as usual for group cohomology. We denote this cohomology by \(H^{\bullet}_{\text{sm}}(G, M)\).

**Theorem 3.3** [Baez and Lauda 2004, Theorem 8.3.7]. There is a one-to-one correspondence between special Lie 2-groups and quadruples \((K_1, K_2, \Phi, \Theta)\) consisting a Lie group \(K_1\), an abelian group \(K_2\), an action \(\Phi\) of \(K_1\) as automorphisms of \(K_2\) and a normalized smooth 3-cocycle \(\Theta : K_1^3 \rightarrow K_2\). Two special Lie 2-groups are isomorphic if and only if they correspond to the same\(^6\) \((K_1, K_2, \Phi)\) and the corresponding 3-cocycles represent the same element in \(H^3_{\text{sm}}(K_1, K_2)\).

**Remark 3.4.** Given a quadruple \((K_1, K_2, \Phi, \Theta)\), the corresponding semistrict Lie 2-group has the Lie group \(K_1\) as the space of objects and the semidirect product Lie group \(K_1 \ltimes_{\Phi} K_2\) as the space of morphisms. The associator is given by \(\Theta\).

**Definition 3.5.** A unital 2-term representation up to homotopy of a Lie group \(G\) consists of

(a) a 2-term complex of vector spaces \(V_1 \xrightarrow{d} V_0\);

(b) a nonassociative action \(F_1\) on \(V_0\) and \(V_1\) satisfying \(dF_1 = F_1d\) and \(F_1(1_G) = \text{Id}\);

and

(c) a smooth map \(F_2 : G \times G \rightarrow \text{End}(V_0, V_1)\) such that

\[
F_1(g_1) \cdot F_1(g_2) - F_1(g_1 \cdot g_2) = [d, F_2(g_1, g_2)]
\]

\(^5\)The notion of strict Lie 2-groups is the same as in [Baez and Lauda 2004].

\(^6\)up to isomorphisms of groups, of course
and

\[ F_1(g_1) \circ F_2(g_2, g_3) - F_2(g_1 \cdot g_2, g_3) + F_2(g_1, g_2 \cdot g_3) - F_2(g_1, g_2) \circ F_1(g_3) = 0. \]  

We denote this 2-term representation up to homotopy of the Lie group \( G \) by \( (V_1 \xrightarrow{d} V_0, F_1, F_2) \). One should be careful: Even if \( F_1 \) is a usual associative action, (32) is not equivalent to \( F_2 \) being a 2-cocycle. This is strangely different from the Lie algebra case (see Section 4). Define \( \tilde{F}_2 : (G \ltimes V_0)^3 \to V_1 \) by

\[ \tilde{F}_2((g_1, \xi_1), (g_2, \xi_2), (g_3, \xi_3)) = F_2(g_1, g_2)(\xi_3). \]

If \( F_1 \) is a usual associative action, we form the semidirect product \( G \ltimes V_0 \). Then \( V_1 \) is a \( G \ltimes V_0 \)-module with an associated action \( \tilde{F}_1 \) of \( G \ltimes V_0 \) on \( V_1 \) given by

\[ \tilde{F}_1(g, \xi)(m) = F_1(g)(m) \quad \text{for all} \ m \in V_1. \]

**Proposition 3.6.** If \( F_1 \) is the usual associative action of the Lie group \( G \) on the complex \( V_1 \xrightarrow{d} V_0 \), then \( \tilde{F}_2 \) defined by (33) is a group 3-cocycle representing an element in \( H^3_{\text{sm}}(G \ltimes V_0, V_1) \).

**Proof.** By direct computation, we have

\[
\begin{align*}
&d \tilde{F}_2((g_1, \xi_1), (g_2, \xi_2), (g_3, \xi_3), (g_4, \xi_4)) \\
&= \tilde{F}_1(g_1, \xi_1) \tilde{F}_2((g_2, \xi_2), (g_3, \xi_3), (g_4, \xi_4)) \\
&\quad - \tilde{F}_2((g_1, \xi_1) \cdot (g_2, \xi_2), (g_3, \xi_3), (g_4, \xi_4)) + \tilde{F}_2((g_1, \xi_1), (g_2, \xi_2) \cdot (g_3, \xi_3), (g_4, \xi_4)) \\
&\quad - \tilde{F}_2((g_1, \xi_1), (g_2, \xi_2), (g_3, \xi_3) \cdot (g_4, \xi_4)) + \tilde{F}_2((g_1, \xi_1), (g_2, \xi_2), (g_3, \xi_3)) \\
&= F_1(g_1) F_2(g_2, g_3)(\xi_4) - F_2(g_1 \cdot g_2, g_3)(\xi_4) + F_2(g_1, g_2 \cdot g_3)(\xi_4) \\
&\quad - F_2(g_1, g_2)(\xi_3 + F_1(g_3)(\xi_4)) + F_2(g_1, g_2)(\xi_3) \\
&= (F_1(g_1) \circ F_2(g_2, g_3) - F_2(g_1 \cdot g_2, g_3) + F_2(g_1, g_2 \cdot g_3) - F_2(g_1, g_2) \circ F_1(g_3))(\xi_4).
\end{align*}
\]

By (32), \( \tilde{F}_2 \) is a Lie group 3-cocycle. \( \square \)

Just as we can associate to any representation of a Lie group a new Lie group that is their semidirect product, we can use a 2-term representation up to homotopy of a Lie group to form a Lie 2-group.

**Theorem 3.7.** Given a 2-term representation up to homotopy \( (V_1 \xrightarrow{d} V_0, F_1, F_2) \) of a Lie group \( G \), its semidirect product with \( G \) is defined to be

\[
\begin{array}{c}
G \times V_0 \times V_1 \\
\xrightarrow{s} \xrightarrow{i} \\
G \times V_0.
\end{array}
\]

Then it is a Lie 2-group with the following structure maps:
The source and target are given by
\[(35) \quad s(g, \xi, m) = (g, \xi) \quad \text{and} \quad t(g, \xi, m) = (g, \xi + dm).\]

The vertical multiplication \(\cdot_v\) is given by
\[(h, \eta, n) \cdot_v (g, \xi, m) = (g, \xi, m + n), \quad \text{where} \ h = g, \ \eta = \xi + dm.\]

The horizontal multiplication \(\cdot_h\) of objects is given by
\[(36) \quad (g_1, \xi) \cdot_h (g_2, \eta) = (g_1 \cdot g_2, \xi + F_1(g_1)(\eta)).\]

The horizontal multiplication \(\cdot_h\) of morphisms is given by
\[(37) \quad (g_1, \xi, m) \cdot_h (g_2, \eta, n) = (g_1 \cdot g_2, \xi + F_1(g_1)(\eta), m + F_1(g_1)(n)).\]

The inverse map \(\text{inv}\) is given by
\[(38) \quad \text{inv}(g, \xi) = (g^{-1}, -F_1(g^{-1})(\xi)).\]

The identity object is \((1_G, 0)\).

The associator
\[a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma)} : ((g_1, \xi) \cdot_h (g_2, \eta)) \cdot_h (g_3, \gamma) \to (g_1, \xi) \cdot_h ((g_2, \eta) \cdot_h (g_3, \gamma))\]
is given by
\[(39) \quad a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma)} = (g_1 \cdot g_2, g_3, \xi + F_1(g_1)(\eta) + F_1(g_1 \cdot g_2)(\gamma), F_2(g_1, g_2)(\gamma)).\]

The unit \(i_{(g, \xi)} : (1_G, 0) \to (g, \xi) \cdot_h \text{inv}(g, \xi)\) is given by
\[(40) \quad i_{(g, \xi)} = (1_G, 0, -F_2(g, g^{-1})(\xi)).\]

All the other natural isomorphisms are identity isomorphisms.

Proof. By (35), (36) and (37), it is straightforward to see that
\[s((g_1, \xi, m) \cdot_h (g_2, \eta, n)) = s(g_1, \xi, m) \cdot_h s(g_2, \eta, n),\]
\[t((g_1, \xi, m) \cdot_h (g_2, \eta, n)) = t(g_1, \xi, m) \cdot_h t(g_2, \eta, n).\]

Thus the multiplication \(\cdot_h\) respects the source and target map. Furthermore, it is not hard to check that the horizontal and vertical multiplications commute, that is,
\[((g, \xi + dm, n) \cdot_h (g', \eta + dp, q)) \cdot_v ((g, \xi, m) \cdot_h (g', \eta, p)) = ((g, \xi + dm, n) \cdot_v (g, \xi, m)) \cdot_h ((g', \eta + dp, q) \cdot_v (g', \eta, p)).\]
or, in terms of a diagram,

\[
\begin{array}{c}
\begin{array}{c}
\bullet \rightarrow (g, \xi) \downarrow m \rightarrow \bullet \rightarrow (g, \xi + \text{d}m) \downarrow n \rightarrow \bullet \rightarrow (g, \xi + \text{d}(m+n)) \downarrow (g', \eta + \text{d}(p+q)) \rightarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\bullet \rightarrow (g', \eta) \downarrow p \rightarrow \bullet \rightarrow (g', \eta + \text{d}p) \downarrow q \rightarrow \bullet \rightarrow (g', \eta + \text{d}(p+q)) \downarrow (g, \xi) \rightarrow \\
\end{array}
\end{array}
\end{array}
\]

(41)

It follows from (31) that the associator \(a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma)}\) defined by (39) is indeed a morphism from \(((g_1, \xi) \cdot_h (g_2, \eta)) \cdot_h (g_3, \gamma)\) to \((g_1, \xi) \cdot_h ((g_2, \eta) \cdot_h (g_3, \gamma))\). To see that it is natural, we need to show that

\[
a_{(g_1, \xi + \text{d}m), (g_2, \eta + \text{d}n), (g_3, \gamma + \text{d}k)} \cdot_h (((g_1, \xi, m) \cdot_h (g_2, \eta, n)) \cdot_h (g_3, \gamma, k))
\]

is equal to

\[
((g_1, \xi, m) \cdot_h ((g_2, \eta, n) \cdot_h (g_3, \gamma, k))) \cdot_h a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma)},
\]

that is, the following diagram commutes:

\[
\begin{array}{c}
\begin{array}{c}
((g_1, \xi) \cdot_h (g_2, \eta)) \cdot_h (g_3, \gamma) \downarrow a \rightarrow (g_1, \xi) \cdot_h ((g_2, \eta) \cdot_h (g_3, \gamma))
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
((g_1, \xi + \text{d}m) \cdot_h (g_2, \eta + \text{d}n)) \cdot_h (g_3, \gamma + \text{d}k) \downarrow a \rightarrow (g_1, \xi + \text{d}m) \cdot_h ((g_2, \eta + \text{d}n) \cdot_h (g_3, \gamma + \text{d}k)).
\end{array}
\end{array}
\end{array}
\]

By straightforward computations, we obtain that (42) is equal to

\[
(g_1 \cdot g_2 \cdot g_3, \\
\xi + F_1(g_1)(\eta) + F_1(g_1 \cdot g_2)(\gamma), m + F_1(g_1)(n) + F_1(g_1 \cdot g_2)(k) + F_2(g_1, g_2)(\gamma + \text{d}k)),
\]

and (43) is equal to

\[
(g_1 \cdot g_2 \cdot g_3, \\
\xi + F_1(g_1)(\eta) + F_1(g_1 \cdot g_2)(\gamma), m + F_1(g_1)(n) + F_1(g_1 \cdot F_1(g_2)(k) + F_2(g_1, g_2)(\gamma)).
\]

Hence (42) is equal to (43) by (31). This implies that \(a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma)}\) as defined by (39) is a natural isomorphism.
By (31) and the fact that $F_1(1_G) = \text{Id}$, the unit given by (40) is indeed a morphism from $(1_G, 0)$ to $(g, \xi) \cdot_h \text{inv}(g, \xi)$. To see that it is natural, we need to prove that
\[
((g, \xi, m) \cdot_h \text{inv}(g, \xi, m)) \cdot_h i_{(g, \xi)} = i_{(g, \xi + dm)},
\]
that is, that the diagram
\[
\begin{array}{ccc}
(1_G, 0) & \xrightarrow{i_{(g, \xi)}} & (g, \xi + dm) \\
\downarrow & & \downarrow \quad \text{inv}(g, \xi + dm) \\
(g, \xi) \cdot_h \text{inv}(g, \xi) & \xleftarrow{(g, \xi, m) \cdot_h \text{inv}(g, \xi, m)} & (g, \xi) \cdot_h \text{inv}(g, \xi)
\end{array}
\]
commutes. This follows from
\[
F_2(g, g^{-1})(dm) = F_1(g) \cdot F_1(g^{-1})(m) - F_1(g \cdot g^{-1})(m) = F_1(g) \cdot F_1(g^{-1})(m) - m,
\]
which is a special case of (31).

Since $F(1_G) = \text{Id}$, we have
\[
(1_G, 0) \cdot_h (g, \xi) = (g, \xi) \quad \text{and} \quad (g, \xi) \cdot_h (1_G, 0) = (g, \xi).
\]
Hence the left unit and the right unit can also be taken as the identity isomorphism.

The counit $e_{(g, \xi)} : \text{inv}(g, \xi) \cdot_h (g, \xi) \to (1_G, 0)$ can be taken as the identity morphism since
\[
\text{inv}(g, \xi) \cdot_h (g, \xi) = (g^{-1}, -F_1(g^{-1})(\xi)) \cdot_h (g, \xi) = (1_G, 0).
\]

Finally, we need to show the pentagon identity for the associator, the triangle identity for the left and right unit laws, and the first and second zig-zag identities. We only give the proof of the pentagon identity; we leave the similar proofs of the others to the reader. In fact, the pentagon identity is equivalent to
\[
\begin{align*}
a_{(g_1, \xi_1), (g_2, \eta), (g_3, \gamma), (g_4, \theta)} & \cdot \nu a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma), (g_4, \theta)} \\
& = (a_{(g_2, \eta), (g_3, \gamma), (g_4, \theta)} \circ (a_{(g_2, \eta), (g_3, \gamma), (g_4, \theta)} \circ (a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma), (g_4, \theta)})) \cdot_h (g_1, \xi).
\end{align*}
\]
By straightforward computations, the left hand side is equal to
\[
(g_1 \cdot g_2 \cdot g_3 \cdot g_4, \xi + F_1(g_1)(\eta) + F_1(g_1 \cdot g_2)(\gamma) + F_1(g_1 \cdot g_2 \cdot g_3)(\theta), \quad F_2(g_1 \cdot g_2 \cdot g_3)(\theta) + F_2(g_1, g_2)(\gamma + F_1(g_3)(\theta))),
\]
and the right hand side is equal to
\[
(g_1 \cdot g_2 \cdot g_3 \cdot g_4, \xi + F_1(g_1)(\eta) + F_1(g_1 \cdot g_2)(\gamma) + F_1(g_1 \cdot g_2 \cdot g_3)(\theta), \quad F_2(g_1, g_2)(\gamma) + F_2(g_1, g_2 \cdot g_3)(\theta) + F_1(g_1) \circ F_2(g_2, g_3)(\theta)).
\]
By (32), they are equal. \qed
4. Integrating the Lie 2-algebra of string type $\mathbb{R} \to \mathfrak{g} \oplus \mathfrak{g}^*$

As an application of Theorem 3.7, we consider the integration of the Lie 2-algebra of string type $\mathbb{R} \to \mathfrak{g} \oplus \mathfrak{g}^*$ given by (19). Now we restrict to the case that $\mathfrak{g}$ is finite-dimensional. Obviously, given a quadruple $(K_1, K_2, \Phi, \Theta)$ that represents a special Lie 2-group (see Theorem 3.3), we obtain by differentiation a quadruple $(\mathfrak{k}_1, \mathfrak{k}_2, \phi, \theta)$, which represents a 2-term skeletal $L_\infty$-algebra.

**Definition 4.1.** A special Lie 2-group that is represented by $(K_1, K_2, \Phi, \Theta)$ is an integration of a 2-term skeletal $L_\infty$-algebra that is represented by $(\mathfrak{k}_1, \mathfrak{k}_2, \phi, \theta)$ if the differentiation of $(K_1, K_2, \Phi, \Theta)$ is $(\mathfrak{k}_1, \mathfrak{k}_2, \phi, \theta)$.

If the differential $d$ in a 2-term complex $V_1 \xrightarrow{d} V_0$ is 0, a representation up to homotopy of Lie algebra $\mathfrak{g}$ on $V_1 \xrightarrow{0} V_0$ consists of two strict representations $\mu_1$ and $\mu_0$, and a linear map $\nu : \mathfrak{g} \wedge \mathfrak{g} \to \text{Hom}(V_0, V_1)$ satisfying equation (6). This equation implies that $\nu$ is a Lie algebra 2-cocycle representing an element in $H^2(\mathfrak{g}, \text{Hom}(V_0, V_1))$, with the representation $[\mu(\cdot), \cdot]$ of $\mathfrak{g}$ on $\text{Hom}(V_0, V_1)$ defined by

$$\mu(\cdot), \cdot](X)(A) \triangleq [\mu(X), A] = \mu_1(X) \circ A - A \circ \mu_0(X) \quad \text{for all } X \in \mathfrak{g}, \ A \in \text{Hom}(V_0, V_1).$$

**Lemma 4.2.** Define $\tilde{\nu} : \bigwedge^3 (\mathfrak{g} \oplus V_0) \to V_1$ by

$$\tilde{\nu}(X_1 + \xi_1, X_2 + \xi_2, X_3 + \xi_3) = \nu(X_1, X_2)(\xi_3) + \text{c.p.}$$

Then $\nu$ is a 2-cocycle if and only if $\tilde{\nu}$ is a 3-cocycle where the representation $\tilde{\mu}$ of $\mathfrak{g} \oplus V_0$ on $V_1$ is given by $\tilde{\mu}(X + \xi)(m) = \mu(X)(m)$.

**Proof.** By direct computations, for any $X_1 + \xi_1, X_2 + \xi_2, X_3 + \xi_3, X_4 + \xi_4 \in \mathfrak{g} \oplus V_0$ with $i = 1, 2, 3, 4$, we have

$$d\tilde{\nu}(X_1 + \xi_1, X_2 + \xi_2, X_3 + \xi_3, X_4 + \xi_4) = d\nu(X_1, X_2, X_3)(\xi_4) + \text{c.p.} \quad \square$$

The Lie algebra homomorphism $\mu$ from $\mathfrak{g}$ to $\text{End}(V_0) \oplus \text{End}(V_1)$ integrates to a Lie group homomorphism $F_1$ from the simply connected Lie group $G$ of $\mathfrak{g}$ to $\text{GL}(V_0) \oplus \text{GL}(V_1)$, with

$$\mu(X) = \frac{d}{dt}
\big|_{t=0} F_1(\exp t X) \quad \text{for all } X \in \mathfrak{g}.$$ 

Consequently, $\text{Hom}(V_0, V_1)$ is a $G$-module with $G$ action

$$g \cdot A = F_1(g) \circ A \circ F_1(g)^{-1} \quad \text{for all } g \in G, \ A \in \text{Hom}(V_0, V_1).$$

The Lie algebra 2-cocycle $\nu : \mathfrak{g} \wedge \mathfrak{g} \to \text{Hom}(V_0, V_1)$ can integrate to a smooth Lie group 2-cocycle $\tilde{F}_2 : G \times G \to \text{Hom}(V_0, V_1)$, satisfying

$$F_1(g_1) \circ (\tilde{F}_2)(g_2, g_3) \circ F_1(g_1)^{-1} - (\tilde{F}_2)(g_1 \cdot g_2, g_3) + (\tilde{F}_2)(g_1, g_2 \cdot g_3) - (\tilde{F}_2)(g_1, g_2) = 0,$$

where $\tilde{F}_2 : G \times G \to \text{End}(V_0) \oplus \text{End}(V_1)$.
and \( F_2(1_G, 1_G) = 0 \). Let us explain how.

The classical theory of cohomology of discrete groups says that the equivalence classes of extensions of \( G \) by a \( G \) module \( M \) are in bijection with the elements of \( H^2(G, M) \). In our case, the same theory tells us that \( H^2_{\text{sm}}(G, \text{Hom}(V_0, V_1)) \) classifies the equivalence classes of splitting extensions of \( G \) by the \( G \)-module \( \text{Hom}(V_0, V_1) \), which is a splitting short exact sequence of Lie groups in which \( \text{Hom}(V_0, V_1) \) is endowed with an abelian group structure.

Thus
\[
\text{Hom}(V_0, V_1) \to \hat{G} \to G.
\]

In a general extension, \( \hat{G} \) is a principal bundle over \( G \); thus it usually does not permit a smooth lift \( G \to \hat{G} \). It permits such a lift if and only if the sequence splits. However in our case, since the abelian group \( \text{Hom}(V_0, V_1) \) is a vector space, we have \( H^1(X, \text{Hom}(V_0, V_1)) = 0 \) for any manifold \( X \). The proof makes use of a partition of unity and is similar to the proof showing that \( H^1(X, \mathbb{R}) = 0 \) for the sheaf cohomology. Hence all \( \text{Hom}(V_0, V_1) \) principal bundles are trivial. Therefore (45) always splits. On the other hand it is well known that when \( G \) is simply connected, there is a one-to-one correspondence between extensions of \( G \) [Brahic 2010, Theorem 4.15] and extensions of its Lie algebra \( \mathfrak{g} \), which in turn are classified by the Lie algebra cohomology \( H^2(\mathfrak{g}, \text{Hom}(V_0, V_1)) \). Hence in our case the differentiation map \( H^2_{\text{sm}}(G, \text{Hom}(V_0, V_1)) \to H^2(\mathfrak{g}, \text{Hom}(V_0, V_1)) \) is an isomorphism. Hence \( \nu \) always integrates to a smooth Lie group 2-cocycle unique up to exact 2-cocycles. Then \( F_2(1_G, 1_G) = 0 \) can be arranged too, because we can always modify the section \( \sigma : G \to \hat{G} \) to satisfy \( \sigma(1_G) = 1_{\hat{G}} \) and the modification of sections results in an exact term. Then combined with (44), it is not hard to see that
\[
F_2(1_G, g) = F_2(g, 1_G) = 0 \quad \text{for all } g \in G.
\]

Thus \( F_2 \) is a normalized 2-cocycle.

**Proposition 4.3.** For any 2-term representation up to homotopy \((\mu, \nu)\) of a Lie algebra \( \mathfrak{g} \) on the complex \( V_1 \xrightarrow{0} V_0 \), there is an associated representation up to homotopy \((F_1, F_2)\) of the Lie group \( G \) on the complex \( V_1 \xrightarrow{0} V_0 \), where \( F_1 \) is the integration of \( \mu \) and \( F_2 : G \times G \to \text{End}(V_0, V_1) \) is defined by
\[
F_2(g_1, g_2) = F_2(g_1, g_2) \circ F_1(g_1 \cdot g_2).
\]

**Proof.** Obviously, (31) is satisfied. To see (32) is also satisfied, combine (47) with (44). By the fact that \( F_1 \) is a homomorphism, we obtain
\[
F_1(g_1) \circ F_2(g_2, g_3) \circ F_1(g_2 \cdot g_3)^{-1} \circ F_1(g_1)^{-1} - F_2(g_1 \cdot g_2, g_3) \circ F_1(g_1 \cdot g_2 \cdot g_3)^{-1} \\
+ F_2(g_1, g_2 \cdot g_3) \circ F_1(g_1 \cdot g_2 \cdot g_3)^{-1} - F_2(g_1, g_2) \circ F_1(g_1 \cdot g_2)^{-1} = 0.
\]
Composing this with \( F_1(g_1 \cdot g_2 \cdot g_3) \) on the right hand side, we obtain (32). \( \square \)

By Proposition 4.3 and Theorem 3.7, we have:

**Theorem 4.4.** Let \( G \) be the simply connected Lie group integrating \( \mathfrak{g} \). Then the Lie 2-algebra of string type \( \mathbb{R} \to \mathfrak{g} \oplus \mathfrak{g}^\ast \) given by (19) integrates to the Lie 2-group

\[
\begin{array}{c}
G \times \mathfrak{g}^\ast \times \mathbb{R} \\
\downarrow s \\
G \times \mathfrak{g}^\ast,
\end{array}
\]

in which the source and target are given by

\[
s(g, \xi, m) = t(g, \xi, m) = (g, \xi),
\]

the vertical multiplication \( \cdot_v \) is given by

\[
(h, \eta, n) \cdot_v (g, \xi, m) = (g, \xi, m + n), \quad \text{where} \quad h = g, \eta = \xi,
\]

the horizontal multiplication \( \cdot_h \) of objects is given by

\[
(g_1, \xi) \cdot_h (g_2, \eta) = (g_1 \cdot g_2, \xi + \text{Ad}_{g_1}^\ast \eta),
\]

the horizontal multiplication \( \cdot_h \) of morphisms is given by

\[
(g_1, \xi, m) \cdot_h (g_2, \eta, n) = (g_1 \cdot g_2, \xi + \text{Ad}_{g_1}^\ast \eta, m + n),
\]

the inverse map \( \text{inv} \) is given by

\[
\text{inv}(g, \xi) = (g^{-1}, -\text{Ad}_{g^{-1}}^\ast \xi), \quad \text{inv}(g, \xi, m) = (g^{-1}, -\text{Ad}_{g^{-1}}^\ast \xi, -m),
\]

the identity object is \((1_G, 0)\), and the associator

\[
a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma)} : \left( (g_1, \xi) \cdot_h (g_2, \eta) \right) \cdot_h (g_3, \gamma) \to (g_1, \xi) \cdot_h \left( (g_2, \eta) \cdot_h (g_3, \gamma) \right)
\]

is given by

\[
a_{(g_1, \xi), (g_2, \eta), (g_3, \gamma)} = (g_1 \cdot g_2 \cdot g_3, \xi + \text{Ad}_{g_1}^\ast \eta + \text{Ad}_{g_1 \cdot g_2}^\ast \gamma, F_2(g_1, g_2)(\gamma)).
\]

All the other structures are identity isomorphisms.

**Proof.** Since \( F_1 \) is a usual associative action, we may modify the unit (40) given in Theorem 3.7 to be the identity natural transformation. It turns out that (48) is a special Lie 2-group and is represented by \((G \times \mathfrak{g}^\ast, \mathbb{R}, \text{Id}, \widehat{F}_2)\), where \( G \times \mathfrak{g}^\ast \) is the semidirect product with the coadjoint action of \( G \) on \( \mathfrak{g}^\ast \), \( \text{Id} \) is the constant map \( G \times \mathfrak{g}^\ast \to \text{Aut}(\mathbb{R}) \) that maps everything to \( \text{Id} \in \text{Aut}(\mathbb{R}) \), and \( \widehat{F}_2 \) is given by

\[
\widehat{F}_2((g_1, \xi_1), (g_2, \xi_2), (g_3, \xi_3)) = F_2(g_1, g_2)(\xi_3) = \overline{F}_2(g_1, g_2) \circ F_1(g_1 \cdot g_2)(\xi_3).
\]
Since $F_2$ is normalized, so is $\tilde{F}_2$. The Lie 2-algebra of string type $\mathbb{R} \to g \oplus g^*$ is skeletal and is represented by $(g \oplus g^*, \mathbb{R}, 0, \tilde{v})$, where $\tilde{v}$ is given by (20). Thus to show that our Lie 2-group is one of its integrations, we only need to show that the differential of the Lie group 3-cocycle $\tilde{F}_2$ is the Lie algebra 3-cocycle $\tilde{v}$. By direct computations [Brylinski 1993, Lemma 7.3.9], we have

\[
\frac{\partial^3}{\partial t_1 \partial t_2 \partial t_3} \sum_{\sigma \in S_3} \varepsilon(\sigma) \tilde{F}_2((e^{\sigma(1)}(t_1), t_3), (e^{\sigma(2)}(t_2), t_3), (e^{\sigma(3)}(t_3), t_3))
\]

\[
= \frac{\partial^3}{\partial t_1 \partial t_2 \partial t_3} \sum_{t_1=0} (\tilde{F}_2(e^{iX_1} \cdot e^{iX_2}, \circ F_1(e^{iX_1} \cdot e^{iX_2})(t_1 \xi_3)) + c.p.
\]

\[
= \frac{\partial^2}{\partial t_1 \partial t_2} \sum_{t_1=0} (\tilde{F}_2(e^{iX_1} \cdot e^{iX_2}) \circ F_1(e^{iX_1})(\xi_3)
\]

\[
+ \tilde{F}_2(e^{iX_1}, 1_G) \circ \frac{\partial}{\partial t_2} \sum_{t_2=0} F_1(e^{iX_1}(\xi_3) + c.p. (by \ (46)))
\]

\[
= \nu(X_1, X_2)(\xi_3) + c.p.
\]

\[
= \tilde{v}(X_1 + \xi_1, X_2 + \xi_2, X_3 + \xi_3) \ (by \ (20)),
\]

which completes the proof. \hfill \Box

**Corollary 4.5.** If Lie algebra $g$ is semisimple, the Lie group 3-cocycle $\tilde{F}_2$ is not exact, that is, $[\tilde{F}_2] \neq 0$ in $H^3_{sm}(G \ltimes g^*, \mathbb{R})$.

**Proof.** By Theorem 4.4, the differentiation of the Lie group 3-cocycle $\tilde{F}_2$ is the Lie algebra 3-cocycle $\tilde{v}$. We only need to show that when $g$ is semisimple, the Lie algebra 3-cocycle $\tilde{v}$ is not exact. This fact is proved in Proposition 2.13. \hfill \Box

**Remark 4.6.** Since $G \ltimes g^*$ is a fibration over $G$, the spectral sequence with $E^{p,q}_2 = H^p_{sm}(G, H^q_{sm}(g^*, \mathbb{R}))$ calculates the group cohomology $H^3_{sm}(G \ltimes g^*, \mathbb{R})$. Since $g^*$ is an abelian group, we have $H^3_{sm}(g^*, \mathbb{R}) = \wedge^3 g^*$. Thus when $G$ is compact, $H^3_{sm}(G, H^3_{sm}(g^*, \mathbb{R})) = (\wedge^3 g^*)^G$ if $p = 0$ and 0 otherwise, where $(\wedge^q g^*)^G$ denotes the set of invariant elements of $\wedge^q g^*$ under the coadjoint action of $G$. Thus when $G$ is compact, $H^3_{sm}(G \ltimes g^*, \mathbb{R}) = (\wedge^3 g^*)^G \neq 0$ because the Cartan 3-form is an element of $(\wedge^3 g^*)^G$.

Our 2-cocycle $F_2$ is unique only up to exact terms. Hence by Theorem 3.3, we need this lemma to verify that our construction is unique up to isomorphism:
Lemma 4.7. If $\bar{F}_2 = d\alpha$ is exact, then $\tilde{F}_2 = d\beta$ is also exact with

$$\beta((g_1, \xi_1), (g_2, \xi_2)) = \alpha(g_1) F_1(g_1)(\xi_2).$$

Proof. It is a direct calculation. Since $\bar{F}_2 = d\alpha$, we have

$$\bar{F}_2(g_1, g_2) = F_1(g_1)\alpha(g_2) F_1(g_1)^{-1} - \alpha(g_1 g_2) + \alpha(g_1).$$

From the definition of $F_2$, we know that

$$F_2(g_1, g_2) = F_1(g_1)\alpha(g_2) F_1(g_1)^{-1} - \alpha(g_1 g_2) F_1(g_1 g_2) + \alpha(g_1) F_1(g_1 g_2).$$

By (50), we have

$$\tilde{F}_2((g_1, \xi_1), (g_2, \xi_2), (g_3, \xi_3)) = F_1(g_1)\alpha(g_2) F_1(g_1)^{-1} F_1(g_1 g_2)(\xi_3) - \alpha(g_1 g_2) F_1(g_1 g_2)(\xi_3) + \alpha(g_1) F_1(g_1 g_2)(\xi_3) = d\beta((g_1, \xi_1), (g_2, \xi_2), (g_3, \xi_3)),$$

since $F_1$ is a group homomorphism. □

Remark 4.8. Our Lie 2-group as a stacky group has the underlying differential stack $G \times g^* \times B\mathbb{R}$. Thus it is 0, 1, 2-connected (that is, it has $\pi_0 = \pi_1 = \pi_2 = 0$) since $\pi_2(B\mathbb{R}) = \pi_1(\mathbb{R}) = 0$ and $\pi_1(B\mathbb{R}) = \pi_0(\mathbb{R}) = 0$. Thus it is the unique 0, 1, 2-connected stacky Lie group integrating the Lie 2-algebra of string type $\mathbb{R} \to g \oplus g^*$ in the sense of [Zhu 2007].
