SYMPLECTIC BIRATIONAL TRANSFORMATIONS OF THE PLANE

JÉRÉMY BLANC

Abstract. We study the group of symplectic birational transformations of the plane. It is proved that this group is generated by SL(2, \mathbb{Z}), the torus and a special map of order 5, as it was conjectured by A. Usnich.

Then we consider a special subgroup \(H\), of finite type, defined over any field which admits a surjective morphism to the Thompson group of piecewise linear automorphisms of \(\mathbb{Z}^2\). We prove that the presentation for this group conjectured by Usnich is correct.

1. Introduction

1.1. The group \(\text{Symp}\). Recall that a rational map \(f: \mathbb{C}^2 \to \mathbb{C}^2\) or a rational transformation of \(\mathbb{C}^2\) is given by

\[(x, y) \mapsto (f_1(x, y), f_2(x, y)),\]

where \(f_1, f_2\) are two rational functions (quotients of polynomials) in two variables. The map \(f\) is said to be birational if it admits an inverse of the same type, which is equivalent to say that \(f\) is locally bijective, or that \(f\) induces an isomorphism between two open dense subsets of \(\mathbb{C}^2\). The group of birational maps of \(\mathbb{C}^2\) is the famous Cremona group.

Following [Usn], we define \(\text{Symp}\) as the group of symplectic birational transformations of the plane, which is the group of birational transformations of \(\mathbb{C}^2\) which preserve the differential form \(\omega_0 = dx \wedge dy\).

In [Usn], a natural surjective morphism from \(\text{Symp}\) to the Thompson group of piecewise linear automorphisms of \(\mathbb{Z}^2\) is constructed (see also [Fav]) although the Thompson group does not embed in the Cremona group. The group \(\text{Symp}\), related to other topics of mathematics, is also an interesting subgroup of the Cremona group, from the geometric point of view. The base-points of its elements are poles of the differential form \(\omega_0\), but its elements can contract curves which are not poles of \(\omega_0\). In this article, we describe the geometry of elements of \(\text{Symp}\), and give proofs to two conjectures of [Usn] (Theorems 1 and 2 below).

1.2. The results. The two groups \(\text{SL}(2, \mathbb{Z})\) and \((\mathbb{C}^*)^2\) naturally embeds into \(\text{Symp}\); the matrix \(\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}(2, \mathbb{Z})\) corresponds to the map \((x, y) \mapsto (x^a y^b, x^c y^d)\), and the pair \((\alpha, \beta) \in (\mathbb{C}^*)^2\) corresponds to \((x, y) \mapsto (\alpha x, \beta y)\). Moreover, the map \(P: (x, y) \mapsto (y, \frac{x+1}{x})\), of order 5, is also an element of \(\text{Symp}\). Our first main result consists of proving the following result, conjectured in [Usn]:

**Supported by the SNSF grant no PP00P2_128422 /1.**
Theorem 1. The group $\text{Symp}$ is generated by $\text{SL}(2, \mathbb{Z})$, $(\mathbb{C}^*)^2$ and $P$.

The map $P$ is a well-known linearisable map ([BB]), and the group $<\text{SL}(2, \mathbb{Z}), (\mathbb{C}^*)^2>$ is a toric well-understood group. The mix of this group with $P$ provides all the complexity to $\text{Symp}$. In the proof, the reader can see that all non-toric base-points come from $P$, but in fact, there are many relations in $\text{Symp}$, and we can have complicated elements with many non-toric base-points.

However, the natural subgroup $H \subset \text{Symp}$ generated by $\text{SL}(2, \mathbb{Z})$ and $P$ is easier to understand. It is an interesting subgroup of finite type of the Cremona group, which is moreover defined over $\mathbb{Q}$ or over any field. We write $C, I$ the elements $C = \begin{pmatrix} -1 & 1 \\ -1 & 0 \end{pmatrix}$ and $I = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ of $\text{SL}(2, \mathbb{Z})$. The presentation $\text{SL}(2, \mathbb{Z}) = <I, C | I^4 = C^3 = [C, I^2] = 1 >$ is classical. We now prove the following result on the relations of $H$, conjectured in [Usn]:

Theorem 2. The following is a presentation of the group $H$:

$$H = <I, C, P | I^4 = C^3 = [C, I^2] = P^5 = 1, PCP = I >.$$ 

The author thanks S. Galkin for asking him these questions in the Workshop on the Cremona group organised by I. Cheltsov in Edinburgh in the beginning of 2010.

2. Some reminders on birational transformations

Recall that any birational transformation of $\mathbb{C}^2$ extends to an unique birational transformation of the projective complex plane $\mathbb{P}^2$ (written also $\mathbb{P}^2_{\mathbb{C}}$ or $\mathbb{CP}^2$) via the embedding $(x, y) \mapsto (x : y : 1)$. We will take $X, Y, Z$ as homogeneous coordinates on $\mathbb{P}^2$, so that the affined coordinates $x, y$ on $\mathbb{C}^2$ correspond to $x = X/Z$ and $y = Y/Z$.

Any birational transformation $\varphi$ of $\mathbb{P}^2$ can be written as

$$\varphi: (X : Y : Z) \dashrightarrow (P_1(X, Y, Z) : P_2(X, Y, Z) : P_3(X, Y, Z)),$$

where the $P_i$ are homogeneous polynomials of the same degree without common factor. The degree of the map is the degree of the $P_i$. If this one is $> 1$, then there is a finite number of points of $\mathbb{P}^2$ where $\varphi$ is not defined, which corresponds to the set of common zeros of $P_1, P_2, P_3$.

More generally, the base-points of $\varphi$ are the points where all curves of the linear system $\sum \lambda_i P_i, \lambda_i \in \mathbb{C}$ pass through. Note that these points are not necessarily on $\mathbb{P}^2$, but maybe in some blow-up, and correspond thus to some tangent directions. See for example [AlC] for more details.

3. Normal cubic forms and geometric descriptions

Note that the divisor corresponding to $\omega_0$ on $\mathbb{P}^2$ is $-(X) - (Y) - (Z)$.

Definition 3.1. We say that a differential form $\omega$ is a normal cubic form if $-\text{div}(\omega)$ is the divisor of a (possibly reducible) singular cubic, whose singular points are ordinary double points.

Note that in the above definition, $-\text{div}(\omega)$ can be either (i) the union of three lines with exactly three double points, (ii) the union of a smooth conic and a line intersecting into two distinct points, (iii) an irreducible cubic curve having an unique ordinary double point. The form $\omega_0$ is a normal cubic form of type (i).
Before using the above definition, we remind the reader the following simple result, already observed in [Usn].

**Lemma 3.2.** Let $\omega$ be a differential form on a smooth algebraic surface $S$ and let $\eta: S \to S$ be the blow-up of $q \in S$. We write $D = \text{div}(\omega)$ the divisor of $\omega$, $D$ its strict transform on $S$, and $E$ the exceptional curve contracted by $\eta$.

Then $\text{div}(\eta^*(\omega)) = D + (m + 1)E$, where $m \in \mathbb{Z}$ is the multiplicity of $D$ at $q$. In particular,

1. $E$ is a zero of $\text{div}(\eta^*(\omega)) \Leftrightarrow D$ has multiplicity $\geq 0$ at $q$.
2. $E$ is a pole of $\text{div}(\eta^*(\omega)) \Leftrightarrow D$ has multiplicity $\leq -2$ at $q$.
3. $E$ is a pole of multiplicity one of $\text{div}(\eta^*(\omega)) \Leftrightarrow D$ has multiplicity $-2$ at $q$.

**Proof.** Let us take some local coordinates $u, v$ on $S$ at $q$ so that this point corresponds to $u = v = 0$. The form $\omega$ locally corresponds to $\varphi(u, v) \cdot du \wedge dv$, where $\varphi$ is a rational function in two variables, and $D$ corresponds to $(\varphi(u, v))$.

The blow-up can be viewed locally as $(u, v) \mapsto (uv, v)$, and $\eta^*(\omega)$ becomes $\varphi(uv, v) \cdot d(uv) \wedge dv = \varphi(uv, v) v \cdot du \wedge dv$. In these coordinates, $v$ is the equation of the divisor $E$ and $\varphi(uv, v)$ corresponds to $\eta^*(\text{div}(\omega))$. Moreover $\varphi(uv, v) = v^m \cdot \psi(u, v)$, where $m \in \mathbb{Z}$ is the multiplicity of $D$ at $q$ (which is the multiplicity of $\varphi$ at $(0, 0)$), and where $\psi(0, 0) \in \mathbb{C}^*$. Observing that $\psi(u, v)$ corresponds to $\tilde{D}$, we obtain the result. \hfill $\square$

We can now relate the base points of birational maps to the image of normal cubic forms:

**Proposition 3.3.** Let $\varphi: \mathbb{P}^2 \to \mathbb{P}^2$ be a birational map, and let $\omega$ be a normal cubic form. The following are equivalent:

1. All base-points of $\varphi$ are poles of $\omega$;
2. The form $\varphi_*(\omega)$ is a normal cubic form.

**Proof.** If $\varphi$ has no base-point, both assertions are trivially true, so we may assume that $\varphi$ has at least one base-point.

We denote by $\eta: S \to \mathbb{P}^2$ the blow-up of all base-points of $\phi$, and by $\epsilon: S \to \mathbb{P}^2$ the morphism $\phi \eta$, which is the blow-up of all base-points of $\phi^{-1}$.

Suppose first that at least one base-point $q$ of $\phi$ (which may be infinitely near to $\mathbb{P}^2$) is not a pole of $\omega$. By Lemma 3.2 the exceptional curve of this point, and of all infinitely near points, are zeros of $\eta^*(\omega)$. Since $q$ is a base-point, at least one of these curves is not contracted by $\eta$, and thus $\varphi_*(\omega) = \epsilon_*(\eta^*(\omega))$ has zeros; it is therefore not a normal cubic form.

Suppose now that all base-points of $\varphi$ are poles of $\omega$. If $-\text{div}(\omega)$ is an irreducible cubic curve, it has an unique ordinary double point, we assume that $\eta$ blows-up this point, by replacing $\eta$ by its composition with the blow-up if needed, obtaining another (non-minimal) resolution of $\varphi$. We now prove the following assertion:

The divisor $D_S = -\text{div}(\eta^*(\omega))$ is linearly equivalent to $-K_S$ and is an effective reduced divisor consisting of a loop of smooth rational curves (i.e. a finite number of smooth rational curves where each one intersect exactly two others, and each intersection is transversal).

Firstly, since $\text{div}(\omega)$ is linearly equivalent to $K_{\mathbb{P}^2}$, we obtain that $D_S$ is equivalent to $-K_S$ by applying Lemma 3.2. Secondly, we recall that $-\text{div}(\omega)$ is an effective divisor, and that it is either a loop of smooth rational curves or an irreducible nodal cubic curve. In this latter case, writing $\mu: \mathbb{F}_1 \to \mathbb{P}^2$ the blow-up of the singular
point, $-\text{div}(\mu^*(\omega))$ is the union of the exceptional curve with the strict transform of the cubic, and is thus a loop of smooth rational curves. We proceed then by induction on the number of points blown-up by $\eta$, applying Lemma 3.2 at each step; blowing-up a smooth point on a loop does not change the structure of the loop, and blowing-up a singular point only adds one component. The assertion is now clear.

The fact that $D_S$ is an effective divisor linearly equivalent to $-K_S$ implies that $D = -\text{div}(\varphi_*(\omega)) = -\text{div}(\epsilon_*(\eta^*(\omega))) = \epsilon_*(D_S)$ is an effective divisor linearly equivalent to $-K_{\mathbb{P}^2}$, and is thus a cubic curve. All components of $D_S$ being rational, $D$ cannot be smooth. It remains to see that all singular points of $D$ are ordinary double points. Writing $\omega' = \varphi_*(\omega)$, if $D = -\text{div}(\omega')$ had one other singularities, we can check using Lemma 3.2 that $D_S = -\text{div}(\epsilon^*(\omega'))$ would not be a loop. \hfill \square

4. Decomposition into quadratic maps

It is well known that any birational transformation of the plane decomposes into quadratic maps. Using Proposition 3.2 we can deduce the same for elements which send a normal cubic form on another one (Lemma 4.1), and then with a more careful study to elements which preserve the divisor of $\omega_0$ (Proposition 4.2).

Lemma 4.1. Let $\varphi : \mathbb{P}^2 \dasharrow \mathbb{P}^2$ be a birational map of degree $d > 1$, and let $\omega$ be a normal cubic form. If $\varphi_*(\omega)$ is a normal cubic form, there exist quadratic transformations $\phi_1, \ldots, \phi_n$ such that

1. $\varphi = \phi_n \circ \cdots \circ \phi_1$;
2. for $i = 1, \ldots, n$, $(\phi_i \circ \cdots \circ \phi_1)_*(\omega)$ is a normal cubic form.

Proof. We start as in the classical proof of Noether-Castelnuovo theorem, by taking a de Jonquières transformation $\psi$ (a birational map of $\mathbb{P}^2$ which preserves a pencil of lines) such that each base-point of $\psi$ is a base-point of $\varphi$ and $\varphi \psi^{-1}$ has degree $< d$. The existence of such a $\psi$ can be checked for example in Chapter 8 of [BJC] (see in particular the proof of Theorem 8.3.4).

Since all base-points of $\varphi$ are poles of $\omega$ (Proposition 3.3), the same is true for $\psi$, so $\psi_*(\omega)$ is a normal cubic form.

It remains thus to prove the lemma in the case where $\varphi$ is a de Jonquières transformation of degree $d > 1$, which preserves the pencil of lines passing through $s \in \mathbb{P}^2$. We prove the result by induction on $d$, the case $d = 2$ being clear. We follow the classical proof of the theorem of Noether-Castelnuovo.

The linear system of $\varphi$ (which is the pull-back by $\varphi$ of the system of lines of the plane) consists of curves of degree $d$ passing through $s$ with multiplicity $d - 1$ and through $2d - 2$ other points $t_1, \ldots, t_{2d-2}$ with multiplicity one.

If at least one of the $t_i$’s is a proper point of $\mathbb{P}^2$, say $t_1$, there exists another $t_j$, say $t_2$, and a quadratic de Jonquières transformation $\phi_1$ with base-points $s, t_1, t_2$. The linear systems of $\phi_1$ and $\varphi$ intersecting into $d - 1$ free points, the map $\varphi \circ (\phi_1)^{-1}$ is a de Jonquières transformation of degree $d - 1$. Since $(\phi_1)_*(\omega)$ is a normal cubic form, the result follows from the induction hypothesis.

If no one of the $t_i$’s is a proper point of the plane, there exists at least one of these, say $t_1$, which corresponds to a tangent direction of $s$, and another point $t_j$, say $t_2$, which is infinitely near to $t_1$. We choose a proper point $u$ in $\mathbb{P}^2$ which is a pole of $\omega$ and which is not aligned with $s$ and $t_1$. There exists a quadratic de Jonquières transformation $\phi_1$ with base-points $s, t_1, u$. The linear systems of $\phi_1$
and \( \varphi \) intersecting into \( d \) free points, the map \( \theta = \varphi \circ (\phi_1)^{-1} \) is a de Jonquières transformation of degree \( d \). The linear system of \( \theta \) is the image by \( \phi_1 \) of the linear system of \( \varphi \); it has one proper base-point distinct from \( q \), which corresponds to the "image" of \( t_2 \) by \( \phi_1 \) (in the decomposition of \( \phi_1 \) into blow-ups and blow-downs, the exceptional curve associated to \( t_1 \) is sent onto two a line of \( \mathbb{P}^2 \) and \( t_2 \) is sent onto a general point of this line). Since \( (\phi_1)_\ast(\omega) \) is a normal cubic form, we can apply the preceding case to \( \theta \).

**Proposition 4.2.** Let \( \varphi: \mathbb{P}^2 \rightarrow \mathbb{P}^2 \) be a birational map of degree \( > 1 \), and assume that

\[
\text{div}(\varphi_\ast(\omega_0)) = \text{div}(\omega_0)
\]

(where \( \omega_0 \) is the differential form \( \frac{dx \wedge du}{xy} \)). Then, there exist quadratic transformations \( \phi_1, \ldots, \phi_n \) such that

1. \( \varphi = \phi_n \circ \cdots \circ \phi_1 \);
2. for \( i = 1, \ldots, n \), \( \text{div}((\phi_i \circ \cdots \circ \phi_1)_\ast(\omega_0)) = \text{div}(\omega_0) \).

**Remark 4.3.** A differential form \( \omega \) satisfies \( \text{div}(\omega) = \text{div}(\omega_0) \) if and only if \( \omega = \mu \omega_0 \) for some \( \mu \in \mathbb{C}^* \). In fact, as we will see after, if a birational map sends \( \omega_0 \) onto \( \omega \), the number \( \mu \) is \( \pm 1 \), and both are possible.

**Proof.** Applying Lemma 4.1 we obtain a decomposition \( \varphi = \phi_n \circ \cdots \circ \phi_1 \) where \( \omega_i = (\phi_i \circ \cdots \circ \phi_1)_\ast(\omega_0) \) is a normal cubic form for \( i = 0, \ldots, n \).

Denote by \( m \) the maximal degree of the irreducible components of \( -\text{div}(\omega_i) \) for \( i = 0, \ldots, n \), denote by \( r \) the minimal index where \( \omega_r \) has a component of degree \( m \). We now prove the result by induction on the pairs \((m, n - r)\), ordered lexicographically.

If \( m = 1 \), \( -\text{div}(\omega_i) \) is the union of three lines for each \( i \). Composing the quadratic maps with an automorphism of \( \mathbb{P}^2 \) which sends \( \text{div}(\omega_i) \) onto \( \text{div}(\omega_0) \), we can assume that \( \text{div}(\omega_i) = \text{div}(\omega_0) \) for each \( i \) and obtain the result.

Suppose now that \( m = 2 \), which implies that \( 0 < r < n \), since \( \omega_0 = \omega_n \neq \omega_r \). The divisor \( -\text{div}(\omega_r) \) is the union of a line \( L \) and a conic \( \Gamma \), and the divisor \( -\text{div}(\omega_{r-1}) \) is the union of three lines. In particular, the curve \( \Gamma_0 = (\phi_{r-1})_\ast(\Gamma) \) is a line and \( L_0 = (\phi_{r-1})_\ast(L) \) is either a point or a line. This implies that the three base-points \( s_1, s_2, s_3 \) of \( \phi_{r-1}^{-1} \) belong to \( \Gamma \) (as proper or infinitely near points) and that at least one of them lies on \( L \). Up to renumbering, \( s_1 \) is one of the two points of \( \Gamma \cap L \), and \( s_2 \) is either a proper point of \( \Gamma \) or the point infinitely near to \( s_1 \) corresponding to the tangent of \( \Gamma \). The curve \( \Gamma_5 = (\phi_{r+1})_\ast(\Gamma) \) is either a conic or a line, so at least two of the three base-points \( t_1, t_2, t_3 \) of \( \phi_{r+1} \) belongs to \( \Gamma \), and \( L_5 = (\phi_{r+1})_\ast(L) \) can be a point, a line or a conic. Up to renumbering, \( t_1 \) is a proper point of \( \Gamma \), and \( t_2 \) is either another proper point of \( \Gamma \), or the point infinitely near to \( t_1 \) corresponding to the tangent direction of \( \Gamma \). We can also assume that if \( t_2 \) belongs to \( \Gamma \cap L \), so does \( t_1 \).

\[
(L_0, \Gamma_0) < \frac{\phi_{r-1}^{-1}}{[s_1, s_2, s_3]} \quad \frac{(L, \Gamma)}{[t_1, t_2, t_3]} = \frac{\phi_{r+1}}{(L_5, \Gamma_5)}
\]

We now define two proper points \( a, b \) of \( \Gamma \). If \( t_1 \in \Gamma \cap L \), the point \( b \) is a general point of \( \Gamma \) (i.e. distinct from the \( s_i \) and \( t_i \)), and otherwise \( b \) is such that \( L \cap \Gamma = \{s_1, b\} \). The point \( a \) is a general point of \( \Gamma \) (i.e. distinct from \( b \) and all \( s_i, t_i \)). We define four birational quadratic maps \( \chi_1, \chi_2, \chi_3, \chi_4 \) of \( \mathbb{P}^2 \), with base points
[s_1, s_2, a], [s_1, a, b], [t_1, a, b] and [t_1, t_2, b] respectively. We moreover set \( \chi_0 = \phi_r^{-1} \) and \( \chi_5 = \phi_{r+1} \). By construction, we have the following: for \( i = 0, \ldots, 4 \), \( \chi_i \) has its three base-points on \( \Gamma \) and at least one of them belongs to \( L \), so \( \Gamma_i = (\chi_i)_*(\Gamma) \) is a line, and \( L_i = (\chi_i)_*(L) \) is either a point or a line; moreover \( \chi_i \) and \( \chi_{i+1} \) have two common base-points, so \( \theta_i = \chi_{i+1} \circ \chi_i^{-1} \) is a quadratic map. We obtain the following commutative diagram:

\[
\begin{array}{c}
(L_0, \Gamma_0) \quad \xymatrix{ & \chi_0 = \phi_r^{-1} & \chi_5 = \phi_{r+1} & (L_5, \Gamma_5) \\
| & [s_1, s_2, s_3] & [t_1, t_2, t_3] & \ar@{^{(}->}[l] \\
\theta_0 & \chi_1 & \chi_3 & \theta_4 \\
| & [s_1, a, b] & [t_1, a, b] & \ar@{^{(}->}[l] \\
(L_1, \Gamma_1) & \ar[r] & \ar[r] & (L_2, \Gamma_2) & \ar[r] & \ar[r] & (L_3, \Gamma_3) & (L_4, \Gamma_4) \\
\theta_1 & \chi_2 & \chi_4 & \theta_3 \\
| & & & \ar@{^{(}->}[l] \\
| & & & \\
| & & & \\
| & & & \\
| & & & \\
| & & & \\
\end{array}
\]

By construction, \(-\text{div}(\chi_i)_*(\omega_r)\) is the union of three lines for \( i = 0, \ldots, 4 \); replacing \( \phi_{r+1} \circ \phi_r \) by \( \theta_2 \theta_3 \theta_2 \theta_0 \), we reduce the pair \((m, n - r)\).

Suppose now that \( m = 3 \) (which implies that \( 1 < r < n - 1 \)). The divisor \(-\text{div}(\omega_r)\) consists of a nodal cubic curve \( \Gamma \). The curve \( \Gamma_0 = (\phi_r^{-1})_*(\Gamma) \) is a conic, so all base-points \( s_1, s_2, s_3 \) of \( \phi_r^{-1} \) belong to \( \Gamma \), and one of them, say \( s_1 \), is the singular point of \( \Gamma \). Up to reordering, we can assume that \( s_2 \) is either a proper point of \( \Gamma \) or the point infinitely near to \( s_1 \) corresponding to the tangent of \( \Gamma \). We denote by \( t_1, t_2, t_3 \) the three base-points of \( \phi_{r+1} \). The curve \( \Gamma_4 = (\phi_{r+1})_*(\Gamma) \) is either a cubic or a conic, which means that either all \( t_i \)'s belong to \( \Gamma \) or that only two belong to \( \Gamma \) but one of these two is the singular point \( s_1 \). If \( s_1 \) is a base-point of \( \phi_{r+1} \), we can assume that \( t_1 = s_1 \), that \( t_2 \) belongs to \( \Gamma \) and that either \( t_2 \) is a proper point of \( \mathbb{P}^2 \) or is infinitely near to \( t_1 = s_1 \). If \( s_1 \) is not equal to any of the \( t_i \), we can assume that \( t_2 \) is a proper point of \( \Gamma \). We choose a general proper point \( a \) of \( \Gamma \), not collinear with any two of the \( s_i, t_i \) and define two birational quadratic maps \( \chi_1, \chi_2 \) on \( \mathbb{P}^2 \), with base points \([s_1, s_2, a]\) and \([s_1, t_2, a]\) respectively. We moreover set \( \chi_0 = \phi_r^{-1} \) and \( \chi_3 = \phi_{r+1} \). By construction, we have the following: for \( i = 0, \ldots, 2 \), \( \chi_i \) has its three base-points on \( \Gamma \) and at least one of them is \( s_1 \), so \( \Gamma_i = (\chi_i)_*(\Gamma) \) is a conic; moreover \( \chi_i \) and \( \chi_{i+1} \) have two common base-points, so \( \theta_i = \chi_{i+1} \circ \chi_i^{-1} \) is a quadratic map. We obtain the following commutative diagram:

\[
\begin{array}{c}
\Gamma_0 \quad \xymatrix{ & \chi_0 = \phi_r^{-1} & \chi_3 = \phi_{r+1} & \Gamma_3 \\
| & [s_1, s_2, s_3] & [t_1, t_2, t_3] & \ar@{^{(}->}[l] \\
\theta_0 & \chi_1 & \chi_2 & \theta_2 \\
| & [s_1, s_2, a] & [s_1, t_2, a] & \ar@{^{(}->}[l] \\
\Gamma_1 & \ar[r] & \ar[r] & \Gamma_2 & \ar[r] & \ar[r] & \ar[r] & \\
\end{array}
\]

By construction, \(-\text{div}(\chi_i)_*(\omega_r)\) is the union of the conic \( \Gamma_i \) and a line for \( i = 0, \ldots, 4 \); replacing \( \phi_{r+1} \circ \phi_r \) by \( \theta_2 \theta_3 \theta_2 \theta_0 \), we reduce the pair \((m, n - r)\). \( \square \)
5. Quadratic elements of \( \text{Symp} \) and the proof of Theorem 1

We now describe some of the main quadratic elements of \( \text{Symp} \), useful in the generation of elements of \( \text{Symp} \) (see Proposition 1).

We fix notation for some points which are poles of \( \omega_0 \). The points \( p_1, p_2, p_3 \) are the vertices of the triangle \( XYZ = 0 \), and \( q_1, q_2, q_3 \) are points on edges:

\[
egin{align*}
\ p_1 &= (1 : 0 : 0) &\ p_2 &= (0 : 1 : 0) &\ p_3 &= (0 : 0 : 1) \\
\ q_1 &= (0 : 1 : -1) &\ q_2 &= (1 : 0 : -1) &\ q_3 &= (1 : -1 : 0)
\end{align*}
\]

Any quadratic birational transformation of \( \mathbb{P}^2 \) has three base-points. We describe now some quadratic transformations, by giving their description on \( \mathbb{C} \), \( X, Y, Z \) of permutations of the variables, generated by \( \rho \) and \( \lambda \) respectively given by \( S_\lambda = (P^2C)^{-1}\rho_{-\lambda}P^2C \) and \( T_\lambda = P^2\rho_{-\lambda}CP^2 \), are described in the following table:

\[
\begin{align*}
\ S_\lambda &= (-\lambda X (X + Y + Z) : Y (X + Y - \lambda Z) : Z (-\lambda X + Y - \lambda Z)) &\ p_1, q_2, q_3 \\
\ T_\lambda &= (X Y : (Y + Z)(\lambda Z - Y) : -\lambda X Z) &\ p_1, q_1, (0 : \lambda : 1)
\end{align*}
\]

Recall that \( C \) is the automorphism \( (X : Y : Z) \mapsto (Y : Z : X) \) of \( \mathbb{P}^2 \), which corresponds to the birational map \( (x, y) \mapsto (y/x, 1/x) \) of \( \mathbb{C}^2 \), and thus to the matrix \( \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \) of \( \text{SL}(2, \mathbb{Z}) \). We denote by \( \text{Sym}_{(X, Y, Z)} \subset \text{Aut}(\mathbb{P}^2) \) the symmetric group of permutations of the variables, generated by \( C \) and \( (X : Y : Z) \mapsto (Y : Z : X) \).

We now describe linear and quadratic elements of \( \text{Symp} \).

Lemma 5.1. The group of automorphisms of \( \mathbb{P}^2 \) which preserve the triangle \( XYZ = 0 \)

is \( (\mathbb{C}^*)^2 \rtimes \text{Sym}_{(X, Y, Z)} \), and its subgroup \( (\mathbb{C}^*)^2 \times \lhd C \rhd \) is equal to the group of automorphisms of \( \mathbb{P}^2 \) which are symplectic.

Proof. Follows from a simple calculation. \( \square \)

Lemma 5.2. Let \( \varphi : \mathbb{P}^2 \rightarrow \mathbb{P}^2 \) be a birational map of degree 2 which has three proper base-points. The following condition are equivalent:

1. \( \text{div}(\varphi_* (\omega_0)) = \text{div}(\omega_0) \).
2. \( \varphi = \alpha Q \beta \), where \( \alpha \in (\mathbb{C}^*)^2 \rtimes \text{Sym}_{(X, Y, Z)} \), \( \beta \in (\mathbb{C}^*)^2 \times \lhd C \rhd \) and \( Q \in \{P^2, P^2, P^3, P^4\} \) or \( Q \in \{S_\lambda, T_\lambda\} \) for some \( \lambda \in \mathbb{C}^* \setminus \{-1\} \).

Proof. The second assertion clearly implies the first one, since \( Q \in \text{Symp} \) is a quadratic map with three proper base-points. It remains thus to prove the other direction.
Denote by $L_1, L_2, L_3 \subset \mathbb{P}^2$ the three lines of equation $X = 0, Y = 0$ and $Z = 0$. Each of the three lines $L_i$ is a pole of $\omega_0$ and its image by $\varphi$ is thus either a point or a line. So for each $i$, one or two of the base-points of $\varphi$ belong to $L_i$.

Denote by $k \in \{0, 1, 2, 3\}$ the number of base-points of $\varphi$ which are vertices of the triangle $XYZ = 0$. Replacing $\varphi$ by $\varphi C$ or $\varphi C^2$ if needed, the $k$ vertices are the $k$ first points of the triple $(p_1, p_2, p_3)$. We will find $Q \in \{I, P, P^2, P^3, P^4, S, T, T^3\}$ and $\beta \in (\mathbb{C}^*)^2 \times \text{Sym}_{(X,Y,Z)}$ such that $\varphi$ and $Q \beta$ have the same base-points.

Before proving the existence of $Q$, $\beta$, let us prove how it yields the result. The fact that $\varphi$ and $Q \beta$ have the same base-points implies that $\varphi = \alpha Q \beta$ for some $\alpha \in \text{Aut}(\mathbb{P}^2)$. Since $\text{div}(\omega_0) = \text{div}(\varphi_*(\omega_0)) = \text{div}(Q_*(\omega_0)) = \text{div}(\beta_*(\omega_0))$, we also have $\text{div}(\alpha_*(\omega_0)) = \text{div}(\omega_0)$, which means that $\alpha \in (\mathbb{C}^*)^2 \times \text{Sym}_{(X,Y,Z)}$ (Lemma 5.1).

We find now $\beta$ and $Q$, by studying the possibilities for $k$.

If $k = 3$, the base-points of $\varphi$ are $p_1, p_2, p_3$ and it suffices to choose $Q = I^2$ and $\beta = 1$.

If $k = 2$, the base-points are $p_1, p_2, u$, where $u \in (L_1 \cup L_2) \setminus L_3$. We choose $\beta \in (\mathbb{C}^*)^2$ which sends $u$ onto $q_1$ or $q_2$, and choose respectively $Q = P$ or $Q = P^4$.

If $k = 1$, the base-points are $p_1, u, v$, where $u \in L_1 \setminus (L_2 \cup L_3)$. If $v \in L_2$ we choose $\beta \in (\mathbb{C}^*)^2$ which sends $u$ onto $q_1$ and $v$ onto $q_2$, and choose then $Q = P^2$. If $v \in L_3$, we choose $\beta = \beta' C^{-1}$, where $\beta' \in (\mathbb{C}^*)^2$, such that $\beta$ sends respectively $p_1, u, v$ onto $q_2, q_1$ and choose $Q = P^3$. If $v \in L_1$, we choose $\beta \in (\mathbb{C}^*)^2$ which sends $u$ onto $q_1 = (0 : -1 : 1)$; the point $v$ is sent onto $(0 : \lambda : 1)$ for some $\lambda \in \mathbb{C}^* \setminus \{1\}$. We can thus choose $Q = T_\lambda$.

If $k = 0$, the base-points are $u, v, w$, which belong respectively to $L_1, L_2, L_3$. We choose $\beta \in (\mathbb{C}^*)^2$ which sends $v$ onto $q_2$ and $w$ onto $q_3$. The point $u$ is sent onto $(0 : \lambda : 1)$, for some $\lambda \in \mathbb{C}^* \setminus \{1\}$ ($\lambda$ is not $-1$ because $u, v, w$ are not collinear). We choose $Q = S_\lambda$.

Now, using all above results, we can prove Theorem 3, which is a direct consequence of the following proposition.

**Proposition 5.3.** The group $\text{Symp}$ is generated by $(\mathbb{C}^*)^2$, $C$ and $P$.

**Proof.** Let $f$ be an element of $\text{Symp}$. If its degree is 1, it is an automorphism of $\mathbb{P}^2$, which is thus generated by $C$ and $P$ (Lemma 5.1).

Otherwise, we write $f = \theta_n \circ \cdots \circ \theta_1$ using Proposition 4.2 and denote by $m$ the number of $\theta_i$ which have at least one base-point which is not a proper point of $\mathbb{P}^2$. We prove the result by induction on the pairs $(m, n)$, ordered lexicographically, the case $m = n = 0$ being induced by Lemma 5.1.

Suppose first that the three base-points of $\theta_1$ are proper base-points of $\mathbb{P}^2$. In this case, we apply Lemma 7.2 and write $\theta_1 = \alpha Q \beta$, where $\alpha \in (\mathbb{C}^*)^2 \times \text{Sym}_{(X,Y,Z)}$, and $Q, \beta$ are generated by $(\mathbb{C}^*)^2$, $C$ and $P$. Replacing $f$ with $f(Q \beta)^{-1}$, we replace the pair $(m, n)$ with $(m, n - 1)$.

Suppose now that at least one base-point of $\theta_1$, say $a$, is not a proper point of $\mathbb{P}^2$. Denote by $L_1, L_2, L_3 \subset \mathbb{P}^2$ the three lines of equation $X = 0, Y = 0$ and $Z = 0$. Each of the three lines $L_i$ is a pole of $\omega_0$ and its image by $\theta_1$ is thus either a point or a line. This means that there is at least one base-point on each of the three lines $L_1, L_2, L_3$, and thus that the two other base-points of $\theta_1$ are proper points $b, c \in \mathbb{P}^2$, and at least one of the two points $b, c$ belongs to $L_i$ for $i = 1, \ldots, 3$. We choose some proper point $d$ of the triangle, not aligned with any two of the points $a, b, c$. There exists a quadratic transformation $Q$ of $\mathbb{P}^2$ with base-points $b, c, d$. 

The map $Q$ sends $\omega_0$ onto a normal cubic form by Proposition 3.3. Moreover, the image of any of the lines $L_1, L_2, L_3$ is a line or a point, so $Q$ sends $\omega_0$ onto a normal cubic form corresponding to a triangle. Replacing $Q$ with its composition with an automorphism of $\mathbb{P}^2$, we may assume that the triangle is $XYZ = 0$. Because $a$ is not aligned with any two of the points $b, c, d$, the linear system of conics passing through $a, b, c$ is sent by $Q$ onto a system of conics with three proper base-points. In consequence, $\theta_1 Q^{-1}$ is a quadratic transformation with three proper base-points. Replacing $\theta_1$ with $(\theta_1 Q^{-1}) \circ Q$, we replace $(m, n)$ with $(m - 1, n + 1)$.

6. The group $H = < \text{SL}(2, \mathbb{Z}), P >$

Let us now focus ourselves on the group $H$ of finite type generated by $\text{SL}(2, \mathbb{Z})$ and $P$, or simply by $C, I, P$ (and in fact only by $P$ and $C$ since $I = PCP$). Recall that $C$ is the automorphism $(X : Y : Z) \mapsto (Y : Z : X)$ of order 3 of $\mathbb{P}^2$ and that $I$ and $P$ have respectively order 4 and 5.

Recall the following notation for the points $p_1, p_2, p_3, q_1, q_2, q_3$.

\[
\begin{align*}
Q_1 &= I = (\frac{1}{1}, x) \\
Q_2 &= I^3 = (y, \frac{1}{1}) \\
Q_3 &= I^2 = (\frac{1}{y}, x) \\
Q_4 &= P = (y, \frac{1}{x}) \\
Q_5 &= P^{-1} = (\frac{x+1}{y}, x) \\
Q_6 &= PI = (\frac{1}{y}, x(y+1)) \\
Q_7 &= P^{-1}I = (\frac{y}{y+1}, 1) \\
Q_8 &= IP = (\frac{x}{x+1}, y) \\
Q_9 &= I = (\frac{x+1}{x}, y) \\
Q_{10} &= P^2 = (\frac{1}{x+y+1}, \frac{x}{x+1}, y) \\
Q_{11} &= P^3C^{-1} = (\frac{x+y+1}{x}, \frac{y}{x+1}, y) \\
Q_{12} &= PIPE = (y, (y+1)x) \\
\end{align*}
\]

Any element of $H$ can be written as a word written with the letters $C, I, P$. We will say that a linear word is a word of type $C^a$ with $a \in \{0, 1, 2\}$. Similarly, we will say that a quadratic word is a word of type $C^aQ, C^b$, where $1 \leq i \leq 12$, $a, b \in \{0, 1, 2\}$. Note that a linear word corresponds to a linear automorphism of $\mathbb{P}^2$ and that a quadratic word corresponds to a quadratic birational transformation of $\mathbb{P}^2$.

We would like to prove that the relations

\[R = \{I^4 = C^3 = [C, I^2] = P^5 = 1; PCP = I\}\]
(which can easily be verified) generate all the others in $H = \langle I, C, P \rangle$. To do this (in Proposition 6.6), we need to prove some technical simple lemmas (Lemmas 6.1, 6.2 and 6.5) and one key proposition (Proposition 6.3).

**Lemma 6.1.** If $Q$ is a quadratic word, then $Q^{-1}$ and $\tau Q \tau^{-1}$ are quadratic words, for any $\tau \in \text{Sym}_{(X,Y,Z)} \subset \text{Aut}(\mathbb{P}^2)$ (permutation of the coordinates).

*Proof.* If $\tau = C$, then $\tau Q \tau^{-1}$ is a quadratic word by definition. We can thus assume that $\tau$ is the map $(X : Y : Z) \mapsto (Y : X : Z)$ (or $(x,y) \mapsto (y,x)$), which conjugates $P, I, C$ to respectively $P^{-1}, I^{-1}, C^{-1}$. If $Q$ is a power of $I$ or of $P$, it is clear that $Q^{-1} = \tau Q \tau^{-1}$ is a quadratic word. It remains to study the case when $Q = Q_i$ with $i \in \{6,7,8,9,12\}$.

First, we do the case of inverses. Since $PCP = I$, we have $(Q_6)^{-1} = I^2 P^{-1} = IPC = Q_9 C$, and thus $(Q_9)^{-1} = CQ_6$. Moreover, $(Q_7)^{-1} = I^2 P = Q_8$. Finally, using $I^4 = 1$ and $I = PCP$, we have

$$(Q_{12})^{-1} = P^{-1} I^{-1} P^{-1} = P^{-1}(PCP)(PCP)P^{-1} = CPIPC = CQ_{12} C.$$  

Now, the conjugation. We have $\tau Q_6 \tau^{-1} = Q_7$ and $\tau Q_8 \tau^{-1} = I^2 P^{-1} = I(PCP)P^{-1} = IPC = Q_8 C$. This implies that $\tau Q_6 \tau^{-1} = Q_8 C$. Finally, $\tau Q_{12} \tau^{-1} = (Q_{12})^{-1}$ is a quadratic word, as we just proved.

**Lemma 6.2.** The words

$$I^a P^{\pm 1}, P^\pm I^a, \ P^\pm I^a P^{\pm 1},$$

where $a \in \mathbb{N}$, are equivalent, up to relations in $R$, to quadratic words.

*Proof.* From the list, we see that any non-trivial power of $I$ or $P$ is a quadratic word. In particular, the case $a = 0$ is trivial. Using $PCP = I$, we find the following tabular:

| $a$ | $I^a P$ | $P^a P$ | $PI^a P^{-1}$ |
|-----|---------|---------|---------------|
| 1   | $I P = Q_9$ | $PIQ_{12}$ | $PPI^{-1} = P^2 C$ |
| 2   | $I^2 P = Q_8$ | $C^{-1} P^{-1} C^{-1}$ | $PIPC = Q_{12} C$ |
| 3   | $P^{-1} C^{-1}$ | $PI^{-1} P^{-1} = C^{-1} P^3$ | |

the result is now clear for $I^a P$, $PI^a P$ and $PI^a P^{-1}$.

For any $a$, the word $I^a P^{-1}$ is equal to $I^{-a}(PCP)P^{-1} = I^{-a} PC$, and is thus also a quadratic word. The words $P^{\pm 1} I^a$ being the inverses of $I^{-a} P^{\pm 1}$, these are also quadratic words (Lemma 6.4). The same holds for $P^{-1} I^a P^{-1} = (PI^{-a} P)^{-1}$. It remains to see that $P^{-1} I^a P$ is a quadratic word for each $a$. Since $I^a = PCI^{a}_P^{-1} C^{-1} P^{-1}$, we find $P^{-1} I^a P = CPI^{a} P^{-1} C^{-1}$, which is quadratic word since $PI^a P^{-1}$ is one.

**Proposition 6.3.** Let $f$ and $g$ be two quadratic words in $H$. If the two quadratic maps associated have two (respectively three) common base-points, then $fg^{-1}$ is equal to a quadratic (respectively linear) word, modulo the relations $R$.

*Proof.* The list of the twelve quadratic words above give the possible base-points of $f$ and $g$: the base-points of $Q_i$ and $CQ_i$ are the same, and the base-points of $Q_i C$ are the image by $C^{-1}$ of the base-points of $h$.

A quick look at the list shows that if $f$ and $g$ have the same three base-points, then $f = C^i g$, for some integer $i$. In particular, $fg^{-1}$ is equal to a linear word. We have thus only to study the case when exactly two of the three base-points of $f$ and $g$ are common.
In the sequel, we will use the following observations: (i) we can exchange the role of \( f \) and \( g \) since \( fg^{-1} \) is a quadratic word if and only if its inverse \( g^{-1}f \) is (Lemma 6.2); (ii) we can replace \( f \) and \( g \) with \( C^if \) and \( C^ig \) since this only multiplies \( fg^{-1} \) by some power of \( C \); (iii) we can replace both \( f \) and \( g \) with their conjugates under any permutation of \((X,Y,Z)\), using Lemma 6.3.

Using (iii), we can "rotate" the two common points by acting with \( C \), which acts as \( p_3 \mapsto p_2 \mapsto p_1 \), \( q_3 \mapsto q_2 \mapsto q_1 \), \( p_3^X \mapsto p_2^X \mapsto p_1^X \) and so on. The possibilities for the two common base-points can thus be reduced to \( \{p_1,p_2\}, \{q_1,q_2\}, \{q_1,q_1^X\} \) or \( \{p_1,u\} \), where \( u \in \{q_1,q_2,q_3,p_1^Y,p_1^Z,p_1^{Y+Z}\} \). Conjugating by \((X:Y:Z) \mapsto (X:Z:Y)\) if needed, \( u \) may be chosen in \( \{q_1,q_2,p_1^Y,p_1^{Y+Z}\} \) only.

We study each case separately.

(a) Case \( \{p_1,p_2\} \) - Using (ii) and reading the list, we can choose that \( f, g \in \{P^{±1}, P^{±1}I^2, I^*\} \) (here the star means any power of \( I \)). If both \( f \) and \( g \) are powers of \( I \), or both are powers of \( P \), so is the product \( fg^{-1} \), and we are done. If \( f \) is a power of \( I \) and \( g \) is a power of \( P \), then \( fg^{-1} \) is equal to \( I^{P±1} \) and the result follows from Lemma 6.2. If \( g = P^{±1}I^3 \) and \( f \) is a power of \( I \), then \( fg^{-1} \) is again equal to \( I^{P±1} \) for some integer \( i \). If \( g = P^{±1}I^2 \) and \( f \) is \( P^{±1} \), then \( fg^{-1} = P^{±1}I^{2P±1} \), which is a quadratic word by Lemma 6.2.

(b) Case \( \{q_1,q_2\} \) - The only possibilities for \( f, g \) are \( P^2 \) or \( P^3 \), and \( fg^{-1} = P^{±1} \).

(c) Case \( \{q_1,q_1^X\} \) - The only possibility is \( f = g = Q_{12} = PIP \), a contradiction.

(d) Case \( \{p_1,q_1\} \) - The third base-point can be respectively \( p_2,p_3,q_2,q_3,p_1^Y,p_1^Z \) or \( q_1^X \), and this corresponds respectively to \( P, P^4C^{-1} = I^3P, P^2, P^3C^{-1} = P^{-1}I^{-1}P \), \( I^2P,I^2P \) and \( I^2P \). In particular, \( f \) and \( g \) are equal to \( f'P \) and \( g'P \) where \( f',g' \in \{P^{±1}, P^{±1}I^1, I^*\} \). Here, \( fg^{-1} \) (or its inverse) belongs to \( \{P^*, I^*, P^{±1}I^*, P^{±1}IP^{±1}\} \) and we are done by Lemma 6.2.

(e) Case \( \{p_1,q_2\} \) - The only possibilities for \( f, g \) are \( P^{-1} \) or \( P^2 \), and \( fg^{-1} = P^{±3} \).

(f) Case \( \{p_1,p_1^Y\} \) - Here \( f, g \in \{I, I^2P\} \) and \( fg^{-1} = (I^2P)^{±1}, \) a quadratic word by Lemma 6.2.

(g) Case \( \{p_1,p_1^{X+Y}\} \) - Here \( f, g \in \{P^2, P^{-1}I^2C^{-1}, P^{-1}C^{-1}I^2\} \) and \( fg^{-1} = (PCP)^{±1} = I^{±1} \).

\[ \square \]

**Corollary 6.4.** Let \( W_1, W_2 \) be two quadratic words. If \( W_2W_1 \) corresponds to a birational map of degree 1 (respectively 2), then \( W_2W_1 \) is equal, modulo the relations \( R \), to a linear word (respectively to a quadratic word).

**Proof.** The map corresponding to \( W_2W_1 \) has degree 1 (respectively 2) if and only if the maps corresponding to \( W_2 \) and \((W_1)^{-1}\) have 3 (respectively 3) common base-points. The result follows then from Proposition 6.3. \[ \square \]

**Lemma 6.5.** Let \( a_1, a_2, a_3 \) be three non-collinear distinct points, such that

- \((Q)\) for \( i = 1,2,3 \), \( a_i \) is a base-point of a quadratic word;
- \((P)\) for \( i = 1,2,3 \), if \( a_i \) is not a proper point of the plane, it is infinitely near to a point \( a_j \), \( j \neq i \);
- \((*)\) for any line \( L \) of the triangle \( XYZ = 0 \) in \( \mathbb{P}^2 \), there exists an \( a_i \) which belongs to \( L \).

Then, there exists a quadratic word \( Q \) having \( a_1, a_2, a_3 \) as base-points.

**Proof.** Let us write \( r = \#\{a_1,a_2,a_3\} \cap \{p_1,p_2,p_3\} \in \{0,1,2,3\} \).

If \( r \geq 2 \), we can assume that \( a_1 = p_1, a_2 = p_2 \) (up to renumbering and multiplying by \( C \) or \( C^2 \)). The last point \( a_3 \) being not collinear to \( a_1 \) and \( a_2 \), and being
a base-point of a quadratic word, it belongs to \{p_1^X, p_2^X, p_3, q_1, q_2, p_3^{y+z}, p_2^{X+Z}\}. We can choose \(Q = Q_i\) for \(i \in \{1, \ldots, 7\}\).

If \(r = 1\), we can assume that \(a_1 = p_1\). Condition (\(\phi\)) implies that \(q_1\) is equal to \(a_2\) or \(a_3\). The possibilities for the remaining point are \(\{p_1^Y, p_1^Z, q_2, q_3, q_1^X\}\), and we can choose \(Q = Q_i\) for \(i \in \{8, \ldots, 12\}\).

The case \(r = 0\) is not possible. Otherwise we would have

\[\{a_1, a_2, a_3\} \subset \{q_1, q_2, q_3^X, q_1^Y, q_2^Z\},\]

which is impossible since \(q_1, q_2, q_3\) are collinear. \(\square\)

**Proposition 6.6.** Let \(W\) be a word in \(I, P, C\). If \(W\) corresponds to a birational map of degree 1 or 2, it is equal, up to relations \(R\), to a linear or quadratic word. In particular, if \(W\) corresponds to the identity of \(\text{Bir}(\mathbb{P}^2)\), it is equal to 1 modulo \(R\).

**Proof.** If \(W\) is a power of \(C\), the result is obvious, so we can write \(W = W_k \cdots W_2 W_1\) where each \(W_i\) is a quadratic word. Note that many such writings exist. We call \(\Lambda_0\) the linear system of lines of \(\mathbb{P}^2\). For \(i = 1, \ldots, k\), we denote by \(\Lambda_i\) the linear system of \(W_i \cdots W_2 W_1(\Lambda_0)\) (identifying here the word with the corresponding quadratic map of \(\mathbb{P}^2\)), and by \(d_i\) its degree. Note that \(d_k \in \{1, 2\}\) is the degree of (the birational map corresponding to) \(W\). We write \(D = \max\{d_i\} i = 1, \ldots, k\) and \(n = \max\{i \mid d_i = D\}\).

Suppose first that \(D = 2\). If \(k > 1\), the map \(W_2 W_1\) has degree 2 or 1 and we can replace it with a single quadratic or linear word (Corollary 6.4). Continuing in this way, we show that \(W\) is equivalent, modulo \(R\), to a linear or a quadratic word.

We suppose now that \(D > 2\), which implies that \(1 < n < k\). We order the pairs \((D, n)\) using lexicographical order, and proceed by induction. Proving that \((D, n)\) can be decreased, we will reduce to the case \(D = 2\) studied before.

If \(r = \deg(W_{n+1} W_n) \in \{1, 2\}\), we can replace \(W_{n+1} W_n\) with a single quadratic or linear word (Corollary 6.4), and this decreases \((D, n)\). We can thus assume that \(r = \deg(W_{n+1} W_n) \in \{3, 4\}\).

We are looking for a quadratic word \(Q\) satisfying the following property:

\[
\begin{align*}
\deg(Q(\Lambda_n)) < d_n &= \deg(\Lambda_n), \\
\{ \deg(QW_n), \deg(W_{n+1}Q^{-1}) \} &= \begin{cases} 
\{2, 2\} & \text{if } r = \deg(W_{n+1} W_n) = 3, \\
\{2, 3\} & \text{if } r = \deg(W_{n+1} W_n) = 4.
\end{cases}
\end{align*}
\]

We first show that such a \(Q\) gives us a way to decrease \((D, n)\), before proving that \(Q\) exists.

If \(r = 3\), both \(Q W_n\) and \(W_{n+1}Q^{-1}\) have degree 2 so are equivalent to, up to relations in \(R\), to quadratic words \(\sigma_1\) and \(\sigma_2\) (Corollary 6.4). Replacing \(W_{n+1} W_n = (W_{n+1}Q^{-1})(QW_n)\) by \(\sigma_2 \sigma_1\), we decrease the pair \((D, n)\). The replacement is described in the following commutative diagram.

\[
\begin{array}{c}
\Lambda_{n-1} \quad W_n \quad \Lambda_n \quad W_{n+1} \\
\sigma_1 \quad Q \quad W_{n+1}Q^{-1} \quad \sigma_2 \\
\Lambda_{n+1} \quad Q(\Lambda_n) \quad W_{n+1} \\
\end{array}
\]

\(\deg(QW_n) = \deg(W_{n+1}Q^{-1}) = 2\)
If \( r = 4 \) and \( \deg(QW_n) = 2 \), \( QW_n \) is equivalent to a quadratic word \( \sigma_0 \). Moreover, since \( \deg(W_{n+1}Q^{-1}) = 3 \) and \( \deg(Q(\Lambda_n)) < D \), we can use the case \( r = 3 \) described before to write \( W_{n+1}Q^{-1} \) as a product of two quadratic words \( \sigma_2\sigma_1 \) satisfying \( \deg(\sigma_1Q(\Lambda)) < D \). The replacement of \( W_{n+1}W_n \) with \( \sigma_2\sigma_1\sigma_0 \), described below, decreases the pair \( (D,n) \).

\[
\begin{align*}
\sigma_1 & \rightarrow \Lambda_n \rightarrow \Lambda_{n+1} \\
\sigma_2 & \rightarrow \Lambda_n \rightarrow \Lambda_{n+1} \\
\sigma_0 & \rightarrow Q(\Lambda_n) \rightarrow QW_n
\end{align*}
\]

\( \deg(QW_n) = 2, \deg(W_{n+1}Q^{-1}) = 3 \)

If \( r = 4 \) and \( \deg(W_{n+1}Q^{-1}) = 2 \), \( W_{n+1}Q^{-1} \) is equivalent to a quadratic word \( \sigma_0 \). We again apply case \( r = 3 \) (since \( \deg(Q(\Lambda_n)) < D \)) to replace \( QW_n \) with a product of two quadratic words \( \sigma_2\sigma_1 \) with \( \deg(\sigma_1(\Lambda_{n-1})) < D \). The replacement of \( W_{n+1}W_n \) with \( \sigma_0\sigma_2\sigma_1 \), described below, decreases the pair \( (D,n) \).

\[
\begin{align*}
\sigma_1 & \rightarrow \Lambda_n \rightarrow \Lambda_{n+1} \\
\sigma_2 & \rightarrow \Lambda_n \rightarrow \Lambda_{n+1} \\
\sigma_0 & \rightarrow Q(\Lambda_n) \rightarrow QW_n
\end{align*}
\]

\( \deg(QW_n) = 3, \deg(W_{n+1}Q^{-1}) = 2 \)

It remains to prove the existence of \( Q \) satisfying the property \((*)\).

We have \( D = d_n = \deg(\Lambda_n) \). The system \( \Lambda_{n+1} = W_{n+1}(\Lambda_n) \) has degree \( d_{n+1} < D \), and \( \Lambda_{n-1} = (W_n)^{-1}\Lambda_n \) has degree \( d_{n-1} \leq D \). Denote respectively by \( S = \{s_1, s_2, s_3\} \) and \( T = \{t_1, t_2, t_3\} \) the base-points of \( W_{n+1} \) and \( (W_n)^{-1} \). For any point \( p \), we will write \( m(p) \) the multiplicity of \( \Lambda_n \) at \( p \). The fact that \( W_{n+1} \) is a quadratic map with base-points \( s_1, s_2, s_3 \) implies that \( d_{n+1} = \deg(W_{n+1}(\Lambda_n)) = 2D - \sum_{i=1}^{3} m(s_i) \). In particular \( \sum_{i=1}^{3} m(s_i) > D \). Similarly, \( d_{n-1} = 2D - \sum_{i=1}^{3} m(t_i) \) and \( \sum_{i=1}^{3} m(t_i) \geq D \).

In order to find \( Q \), we will find its three base-points. We are looking for three distinct points \( a_1, a_2, a_3 \in S \cup T \) which satisfy the following conditions:

\[
\begin{align*}
\sum_{i=1}^{3} m(a_i) & > D, \\
\{a_1, a_2, a_3\} \cap S, \{a_1, a_2, a_3\} \cap T & = \left\{ \begin{array}{ll} 
\{2, 2\} & \text{if } r = \deg(W_{n+1}W_n) = 3, \\
\{1, 2\} & \text{if } r = \deg(W_{n+1}W_n) = 4.
\end{array} \right.
\end{align*}
\]

\( \diamond \) For each line \( L \) of the triangle \( XYZ = 0 \) one \( a_i \) belongs to \( L \).

The condition \( \sum_{i=1}^{3} m(a_i) > D \) implies that the three points are not collinear (because \( \Lambda_n \) has no fixed component). Replacing a point \( a_i \) by \( a'_i \) if \( a_i \) is infinitely near to \( a'_i \) and if \( a'_i \notin \{a_1, a_2, a_3\} \), and then applying condition \( \diamond \), we get a quadratic word \( Q \) having \( a_1, a_2, a_3 \) as its base-points (Lemma 6.5). Condition \((**)\) implies then \((*)\).

It remains to find the three points \( a_1, a_2, a_3 \) satisfying \((**)\) and \( \diamond \). This is now done separately in the cases \( r = 3 \) and \( r = 4 \).
Suppose that \( r = 3 \), which means that \( S \cap T = \{ u \} \), for some proper point \( u \) of the plane. We order the points of \( S \) and \( T \) such that \( S = \{ u, s_1, s_2 \} \), \( T = \{ u, t_1, t_2 \} \), with \( m(s_1) \geq m(s_2) \) and \( m(t_1) \geq m(t_2) \). We observe that at least one of the inequalities \( m(u) + m(t_1) + m(s_2) > D \), \( m(u) + m(s_1) + m(t_2) > D \) is satisfied. Indeed, otherwise the sum would give \( \sum_{i=1}^{3} m(s_i) + \sum_{i=1}^{3} m(t_i) \leq 2D \), which is impossible. We assume first that \( m(u) + m(s_1) + m(t_2) > D \), and write \( A_1 = \{ u, s_1, t_1 \} \), \( A_2 = \{ u, s_1, t_2 \} \). For \( i = 1, 2 \), we have \( \sum_{p \in A_i} m(p) \geq m(u) + m(s_1) + m(t_2) > D \), and thus the three points of \( A_i \) satisfy condition \((*)\) and in particular are not collinear. We claim now that at least one of the two sets \( A_1, A_2 \) satisfies condition \((\diamond)\). Suppose the converse for contradiction. This means that for \( i = 1, 2 \), there exists a line \( L_i \) in the standard triangle \( XYZ = 0 \) such that \( L_i \cap A_i = \emptyset \). Since \( T = \{ u, t_1, t_2 \} \) satisfies condition \((\diamond)\), we see that \( t_1 \in L_2 \setminus L_1 \) and \( t_2 \in L_1 \setminus L_2 \), in particular \( L_1 \neq L_2 \).

Denoting by \( L_3 \) the last line of the triangle, we have \( u, s_1 \in L_3 \setminus (L_1 \cup L_2) \). Since \( t_1 \) and \( t_2 \) are not collinear with \( u \) and \( s_1 \), both do not belong to \( L_3 \). This implies that \( T = \{ u, t_1, t_2 \} = \{ q_1, q_2, q_3 \} \), which is impossible since \( q_1, q_2, q_3 \) are collinear (they belong to the line \( X + Y + Z = 0 \)). The case \( m(u) + m(t_1) + m(s_2) > D \) is the same, by just exchanging \( S \) and \( T \) in the proof.

Suppose that \( r = 4 \), which means that \( S \cap T = \emptyset \). We order the points \( s_i \) and \( t_i \) such that \( m(s_1) \geq m(s_2) \geq m(s_3) \) and \( m(t_1) \geq m(t_2) \geq m(t_3) \). We observe that at least one of the inequalities \( m(s_1) + m(t_2) + m(t_3) > D \), \( m(t_1) + m(s_2) + m(s_3) > D \) is satisfied. Indeed, otherwise the sum would give \( \sum_{i=1}^{3} m(s_i) + \sum_{i=1}^{3} m(t_i) \leq 2D \), which is impossible. We assume first that \( m(s_1) + m(t_2) + m(t_3) > D \), and write \( A_1 = \{ s_1, t_2, t_3 \} \), \( A_2 = \{ s_1, t_1, t_3 \} \), \( A_3 = \{ s_1, t_1, t_2 \} \). For \( i = 1, 2, 3 \), we have \( \sum_{p \in A_i} m(p) \geq m(s_1) + m(t_2) + m(t_3) > D \), and thus the three points of \( A_i \) satisfy condition \((**.)\). We claim now that at least one of the three sets \( A_i \) satisfies condition \((\diamond)\). Suppose the converse for contradiction. This means that for \( i = 1, 2, 3 \), there exists a line \( L_i \) in the standard triangle such that \( L_i \cap A_i = \emptyset \). Since \( T \cap L_i \neq \emptyset \), we have \( t_i \in L_i \) for each \( i \) and \( t_i \notin L_j \) for \( i \neq j \). This implies that the three points \( t_i \) are contained in \( \{ q_1, q_2, q_3, q_1^X, q_2^Y, q_3^Z \} \), which is impossible because \( T = \{ t_1, t_2, t_3 \} \) is the set of base-points of a quadratic word (we can see this on the list of base-points of quadratic words, or simply observe that \( q_1, q_2, q_3 \) are collinear). The case \( m(t_1) + m(s_2) + m(s_3) > D \) is the same, by just exchanging \( S \) and \( T \) in the proof.
