Abstract

Weakly supervised object localization (WSOL) is a challenging problem when given image category labels but requires to learn object localization models. Optimizing a convolutional neural network (CNN) for classification tends to activate local discriminative regions while ignoring complete object extent, causing the partial activation issue. In this paper, we argue that partial activation is caused by the intrinsic characteristics of CNN, where the convolution operations produce local receptive fields and experience difficulty to capture long-range feature dependency among pixels. We introduce the token semantic coupled attention map (TS-CAM) to take full advantage of the self-attention mechanism in visual transformer for long-range dependency extraction. TS-CAM first splits an image into a sequence of patch tokens for spatial embedding, which produce attention maps of long-range visual dependency to avoid partial activation. TS-CAM then re-allocates category-related semantics for patch tokens, enabling each of them to be aware of object categories. TS-CAM finally couples the patch tokens with the semantic-agnostic attention map to achieve semantic-aware localization. Experiments on the ILSVRC/CUB-200-2011 datasets show that TS-CAM outperforms its CNN-CAM counterparts by 7.1%/27.1% for WSOL, achieving state-of-the-art performance. Code is available at https://github.com/vasgaowei/TS-CAM

1. Introduction

Weakly supervised learning refers to methods that utilize training data with incomplete annotations to learn recognition models. Weakly supervised object localization (WSOL) solely requires the image-level annotations indicating the presence or absence of a class of objects in images to learn localization models [21, 22, 25, 43]. WSOL has attracted increasing attention as it can leverage the rich Web images with tags to learn object-level models [43].

As the cornerstone of WSOL [6], the Class Activation Mapping (CAM) [51] utilizes the activation map from the last convolution layer to generate semantic-aware localization maps for object bounding-box estimation. However, CAM suffers from severe underestimation of object regions because the discriminative regions activated through the classification models are often much smaller than objects’ actual extent [2]. Local discriminative regions are capable of minimizing image classification loss, but experience difficulty for accurate object localization [43], Fig. 1(b). Much effort has been made to solve this problem by proposing

Figure 2. Comparison of the mechanisms of (a) CNN-based CAM, (b) Transformer-based Attention and (c) the proposed TS-CAM. The CNN-based CAM method is limited by the small-range feature dependency and the transformer-based attention is limited by the semantic-agnostic issue. TS-CAM is able to produce semantic coupled attention maps for complete object localization. (Best viewed in color)

various regularizations [47, 48, 43, 19, 20], divergent activation [30, 43, 45] or adversarial training [7, 20, 40, 47, 45, 30]. However, there is very little work to pay attention to fundamentally solving the inherent defects of CNN’s local representation, Fig. 2(a). Capturing the long-range feature dependency, which can be interpreted as the semantic correlation between features in different spatial locations, is critical for WSOL.

Recently, visual transformer has been introduced to the computer vision area. Visual transformer [9] constructs a sequence of tokens by splitting an input image into patches with positional embedding and applying cascaded transformer blocks to extract visual representation. Thanks to the self-attention mechanism and Multilayer Perceptron (MLP) structure, visual transformers can learn complex spatial transforms and reflect long-range semantic correlations adaptively, which is crucial for localizing full object extent, Fig. 1(d). Nevertheless, visual transformer cannot be directly mitigated to WSOL for the following two reasons: (1) When using patch embeddings, the spatial topology of the input image is destroyed, which hinders the generation of activation maps for object localization. (2) The attention maps of visual transformers are semantic-agnostic (not distinguishable to object classes) and are not competent to semantic-aware localization, Fig. 2(b).

In this study, we propose the token semantic coupled attention map (TS-CAM), making the first attempt for weakly supervised object localization with visual transformer. TS-CAM introduces a semantic coupling structure with two network branches, Fig. 2(c), one performs semantic reallocation using the patch tokens and the other generates semantic-agnostic attention map upon the class tokens. Semantic re-allocation, with class-patch semantic activation, enables the patch tokens to be aware of object categories. The semantic-agnostic attention map aims to capture long-distance feature dependency between patch tokens by taking the advantages of the cascaded self-attention modules in transformer. TS-CAM finally couples the semantic-aware maps with the semantic-agnostic attention map for object localization, Fig.

The contributions of this work are as follows:

- We propose the token semantic coupled attention map (TS-CAM), as the first solid baseline for WSOL using visual transformer by leveraging the long-range feature dependency.
- We propose the semantic coupling module to combine the semantic-aware tokens with the semantic-agnostic attention map, providing a feasible way to leverage both semantics and positioning information extracted by visual transformer for object localization.
• TS-CAM achieves a substantial improvement over previous methods on two challenging WSOL benchmarks, fully exploiting the long-range feature dependency in the visual transformer.

2. Related Work

Weakly Supervised Object Localization (WSOL) aims to learn object localizations given solely image-level category labels. A representative study of WSOL is CAM [51], which produces localization maps by aggregating deep feature maps using a class-specific fully connected layer. By removing the last fully connected layer, CAM can also be implemented by fully convolutional networks [14].

Despite the simplicity and effectiveness of CAM-based methods, they suffer identifying small discriminative parts of objects. To improve the activation of CAMs, HaS [30] and CutMix [30] adopted adversarial erasing on input images to drive localization models focusing on extended object parts. ACoLo [47] and ADL [7] instead erased feature maps corresponding to discriminative regions and used adversarially trained classifiers to recover missed parts. SPG [48] and I2C [49] increased the quality of localization maps by introducing the constraint of pixel-level correlations into the network. DANet [43] applied a divergent activation to learn complementary visual cues for WSOL. SEM [50] refined the localization maps by using the point-wise similarity within seed regions. GC-Net [19] took geometric shapes into account and proposed a multi-task loss function for WSOL.

Most of the above methods struggled to expand activation regions by introducing sophisticated spatial regularization techniques to CAM. However, they remain puzzled by the contradiction between image classification and object localization. As observed by the visualization approaches [3, 46], CNNs tend to decompose an object into local semantic elements corresponding local receptive fields. Activating a couple of the semantic elements could bring good classification results. The problem about how to collect global cues from local receptive fields remains.

Weakly Supervised Detection and Segmentation are vision tasks closely related to WSOL. Weakly supervised detection train networks to simultaneously perform image classification and instance localization [38, 36, 24]. Given thousands of region proposals, the learning procedure selects high-scored instances from bags while training detectors. In a similar way, weakly supervised segmentation trains classification networks to estimate pseudo masks which are further used for training the segmentation networks. To generate accurate pseudo masks, [16, 1, 13, 38] resorted to a region growing strategy. Meanwhile, some researchers investigated to directly enhance the feature-level activated regions [17, 41]. Others accumulate CAMs by training with multiple phases [15], exploring boundary constraint [5], leveraging equivalence for semantic segmentation [39], and mining cross-image semantics [32] to refine pseudo masks.

Similar to WSOL, many weakly supervised detection and segmentation approaches are prone to localize object parts instead of full object extent. There is a requirement to explore new classification models to solve the partial activation problem in a systematic way.

Long-Range Feature Dependency. CNNs produce a hierarchical ensemble of local features with different reception fields. Unfortunately, most CNNs [28, 11] are good at extracting local features but experience difficulty to capture global cues.

To alleviate such a limitation, one solution is to utilize pixel similarity and global cues to refine activation maps [38, 39, 49, 50]. Cao et al. [4] found that the global contexts modeled by non-local networks are almost the same for query positions and thereby proposed NLNet [38] with SENet [12] for global context modeling. MST [31] proposed the learnable tree filter to capture the structural property of minimal spanning tree to model long-range dependencies. The other solution is the attention mechanism [37, 23]. The non-local operation [37] was introduced to CNNs in a self-attention manner so that the response at each position is a weighted sum of the features at all (global) positions. SASA [23] verified that self-attention is an effective stand-alone layer for CNNs. Relation Networks [8] proposed to process a set of objects simultaneously through interaction between their features and geometry, allowing modeling the spatial relations between objects. Recent studies introduced a cascaded self-attention mechanism in the transformer model to capture long-range feature dependency [42, 34, 44].

3. Methodology

In this section, we first give the preliminaries for visual transformer. We then introduce the TS-CAM method. We finally analyze TS-CAM by feature visualization and feature dependency quantification.

3.1. Preliminaries

For visual transformer [9], an input image $x$ of $W \times H$ resolution is divided to $w \times h$ patches, where $w = W/P$, $h = W/P$ and $P$ denotes the width/height of a patch. The divided patches are flattened and linearly projected to construct $N = w \times h$ patch tokens $\{t_u \in \mathbb{R}^{1 \times D}, u = 1, 2, ..., N\}$ and a class token $t_0 \in \mathbb{R}^{1 \times D}$, Fig. 3. $D$ stands for the dimension of each token embedding. The class token $t_0$ is learnable with random initialization. Each token is added with a learnable position embedding in an element-wised manner. These tokens are fed to $L$ cascaded transformer blocks, each of which consists of a multi-head self-attention layer and a Multilayer Perceptron (MLP) block.

Denote $t_n$ and $t_0$ as the $n$-th patch token and the class token of the $l$-th transformer block, respectively. The last
embedded class token $t^L$ is fed to an MLP block to predict the classification probability, as

$$p = \text{Softmax} \left( \text{MLP}(t^L) \right),$$  \hspace{1cm} (1)

where $p \in \mathbb{R}^{1 \times C}$ and $C$ denotes the number of classes. $p_c$ denotes the predicted probability to class $c$. MLP($\cdot$) denotes the classification function implemented by the MLP block. Denote the ground-truth label for image $x$ as $y \in \{1, 2, ..., C\}$, the classification loss function is defined as

$$\mathcal{L}_T = - \log p_y,$$  \hspace{1cm} (2)

which is used to train the visual transformer.

### 3.2. TS-CAM

As shown in Fig. 3, patch token embeddings of the $L$-th visual transformer block are concatenated and transposed as $t^L \in \mathbb{R}^{D \times N}$. They are then reshaped to token feature maps $t^L_d \in \mathbb{R}^{D \times w \times h}$, where $t^L_d, d \in \{1, 2, ..., D\}$ denotes the $d$-th feature map. The semantic aware map $S_c$ of class $c$ is calculated by convolution as

$$S_c = \sum_d t^L_d * k_{c,d},$$  \hspace{1cm} (3)

where $k \in \mathbb{R}^{C \times D \times 3 \times 3}$ denotes the convolution kernel and $k_{c,d}$ is a $3 \times 3$ kernel map indexed by $c$ and $d$. $*$ is the convolution operator. To produce semantic-aware maps, the loss function defined in Eq. 2 is updated to

$$\mathcal{L}'_T = - \log p'_y$$

$$= - \log \frac{\exp \left( \sum_c S_{n,c} / N \right)}{\sum_c \exp \left( \sum_c S_{n,c} / N \right)},$$  \hspace{1cm} (4)

where $S_{n,c}$ is the semantic of the $n$-th patch token for class $c$. While optimizing Eq. 1 allocates the semantics to class token $t^L$, minimizing Eq. 4 re-allocates the semantics to patch tokens $\{t^L_1, t^L_2, ..., t^L_N\}$, generating semantic-aware maps for WSOL.

**Semantic-agnostic Attention Map.** To fully exploit the long-range feature dependency of visual transformer, we propose to aggregate the attention vectors of the class token to generate the semantic-agnostic attention map. Denote $t^l \in \mathbb{R}^{(N+1) \times D}$ as the input of transformer block $l$, which is calculated by concatenating the embeddings of all tokens. In the self-attention operation in the $(l)$-th transformer block,
the embedded tokens \( \hat{t}_l \) is computed as
\[
\hat{t}_l = \text{Softmax} \left( (t^l \theta^l_q)(t^l \theta^l_k)^\top / \sqrt{D} \right) (t^l \theta^l_v),
\]
where \( \theta_q^l, \theta_k^l, \text{and } \theta_v^l \) respectively denote parameters of the linear transformation layers of self-attention operation in \((l)-th\) transformer block. \( \top \) is a transpose operator. \( A^l \) is the attention matrix while \( A^l_s \in \mathbb{R}^{1 \times (N+1)} \) is the attention vector of the class token. In the multi-head attention layer where \( K \) heads are considered, \( D \) in Eq. 5 is updated as \( D' \), where \( D' = D/K \). \( A^l_s \) is then updated as the average of attention vectors from \( K \) heads.

Eq. 5 implies that \( A^l_s \) records the dependency of the class token to all tokens by the matrix multiplication operation.

Eq. 5 implies that the embedding \( \hat{t}_l \) of class token of the self-attention operation is calculated by multiplying its attention vector \( A^l_s \) with the embedding \( t^l \) in the \((l)-th\) transformer block. \( \hat{t}_l \) is therefore able to “see” all patch tokens, where \( A^l_s \) implies how much attention is paid on each token. When Eq. 4 is optimized, the attention vector \( A^l_s \) is driven to focus on object regions (e.g., long-range features of semantic correction) for image classification. The final attention vector \( A_s \) is defined as
\[
A_s = \frac{1}{L} \sum_l A^l_s,
\]
which aggregates attention vectors \( (A^l_s) \) and collects feature dependency from cascaded transformer blocks to indicate full object extent.

**Semantic-Attention Coupling.** As the attention vector \( A_s \) is semantic-agnostic, we use an element-wise multiplication to couple it with the semantic-aware maps to obtain the semantic-coupled attention map \( M_c \) for each class \( c \), Fig. 3. The coupling procedure is formulated as
\[
M_c = \Gamma^{w \times h}(A_s) \otimes S_c,
\]
where \( \otimes \) denotes an element-wise multiplication and addition operations. \( \Gamma^{w \times h}(\cdot) \) denotes the reshape function which converts the attention vector \( (\mathbb{R}^{1 \times N}) \) to the attention map \((\mathbb{R}^{w \times h}) \). \( M_c \) is up-sampled to a semantic-aware localization map, which is used for object bounding box prediction with a thresholding approach [48].

3.3. Analysis of TS-CAM

**Feature Visualization.** In Fig. 4, we visualize the feature maps of CNN and TS-CAM. The feature maps are randomly selected from different blocks/layers. It can be seen that the feature maps of CNN tend to activate local discriminative regions. In contrast, the feature maps of TS-CAM are able to activate full object extent.

**Long-Range Feature Dependency.** In Fig. 5 right, we quantify the feature dependency ranges by using the cosine similarity between patch token embeddings (features). It can be seen that not only on the diagonal lines but also on the first and last rows/columns, the similarity values are significant despite the larger distance between them, Fig. 5 left. The similarity matrix shows that long-range feature dependency is captured by TS-CAM.

4. Experiments

4.1. Experimental Settings

**Datasets.** TS-CAM is evaluated on two commonly used benchmarks, i.e., CUB-200-2011 [35] and ILSVRC [26]. CUB-200-2011 is a fine-grained bird dataset with 200 different species, which is split into the training set of 5,994 images and the test set of 5,794 images. In ILSVRC, there are around 1.2 million images about 1,000 categories for training and 50,000 images for validation. The model is trained on the training set and evaluated on the validation set where the bounding box annotations are solely used for evaluation.

**Evaluation Metrics.** Top-1/Top-5 classification accuracy (Top-1/Top-5 Cls. Acc), Top-1/Top-5 localization accuracy
(Top-1/Top-5 Loc. Acc.), and Localization accuracy with ground-truth class (Gt-Known Loc. Acc) are adopted as evaluation metrics following baseline methods [26, 48, 51]. For localization, a prediction is positive when it satisfies: the predicted classification is correct; the predicted bounding boxes have over 50% IoU with at least one of the ground-truth boxes. Gt-Known indicates that it considers localization regardless of classification.

**Implementation Details.** TS-CAM is implemented based on the Deit backbone [34], which is pre-trained on ILSVRC [26]. Each input image is re-scaled to 256×256 pixels, and randomly cropped by 224×224 pixels. We remove the MLP head, and add one convolution layer with kernel size 3×3, stride 1, pad 1 with 200 output units (1000 units for ILSVRC). The newly added layer is initialized following He’s approach [10]. When training WSOL models, we use AdamW [18] with $\epsilon=1e-8$, $\beta_1=0.9$ and $\beta_2=0.99$ and weight decay of 5e-4. On CUB-200-2011, the training procedure lasts 60 epochs with learning rate 5e-5 and batch-size 128. On ILSVRC dataset, training carries out 12 epochs with learning rate 5e-4 and batch-size 256.

### 4.2. Performance

**Main Results.** Table 1 compares TS-CAM with other methods on the CUB-200-2011. TS-CAM with a Deit-S backbone [34] outperforms the baseline methods on Top-1, Top-5, and Gt-Known metrics by a surprisingly large margin, yielding the localization accuracy of Top-1 71.3%, and Top-5 83.8%. Compared with the state-of-the-art methods (RCAM [50] and MEIL [20]), it respectively achieves gains of 12.3% and 13.8% in terms of Top-1 Loc. Acc. The left part of Fig. 6 compares localization examples by CAM [51], Transformer-based Attention, and TS-CAM on the CUB-200-2011. TS-CAM preserves global structures and covers more extent of objects. By solely utilizing the attention map from transformer structure, TransAttention highlights most object parts, but fails to precisely localize full objects due to the lack of category semantics.

In Table 2, we compare TS-CAM with its CNN counterparts (CAM) and the SOTAs on the localization accuracy by using tight bounding boxes on the ILSVRC. TS-CAM respectively outperforms CAM on the VGG16 [29] by 10.6% and 9.4% in terms of Top-1 Loc. Acc and Top-5 Loc. Acc. Compared with SOTAs with the VGG16 backbone [29], TS-CAM outperforms by $\sim$ 6% and $\sim$ 4% in terms of Top-1 Loc. Acc and Top-5 Loc. Acc. Compared with I$^2$C, TS-CAM achieves performance gains of 6.0% Top-1 Loc. Acc and 5.8% Top-5 Loc. Acc, which are significant margins to the challenging problem. Compared with SOTAs on the well-designed Inception V3 [33], TS-CAM also achieves the best performance. Specifically, TS-CAM achieves performance gains of 7.1% and 6.1% in terms of Top-1 and Top-5 Loc. Acc compared with CAM. Compared with I$^2$C which leverages pixel-level similarities across different objects to prompt the consistency of object features within the same categories, TS-CAM achieves comparable results with a cleaner and simpler pipeline. The right half of Fig. 6 illus-

Figure 7. Comparison of localization accuracy under IoUs on CUB-200-2011 [35]. Lighter color means Gt-Known Loc. Acc.

Table 3. Comparison of parameters and MACs. TS-CAM is implemented based on Deit-S [34]. And Top-1 Loc. Acc. is evaluated on the CUB-200-2011 test set [35].

| Methods | Image size | #Params (M) | MACs (G) | Top-1 Loc. Acc. % |
|---------|------------|-------------|----------|------------------|
| VGG16-CAM | 224\(^2\) | 19.6 | 16.3 | 44.2 |
| GoogleNet-CAM | 224\(^2\) | 16.7 | 13.5 | 41.1 |
| TS-CAM (Ours) | Deit-S | 23.1 | 5.29 | 71.3 |

Table 4. Localization error statistics.

| Methods | ILSVRC(%) | CUB-2011-200(%) |
|---------|-----------|-----------------|
| VGG16 | M-Ins | Part | More | M-Ins | Part | More |
| TransCAM | 10.65 | 3.55 | 9.58 | - | 21.91 | 10.53 |
| TS-CAM (Ours) | 10.36 | 3.22 | 9.49 | - | 23.09 | 5.52 |

forms VGG16-CAM (with 19.6M parameters and 16.3G MACs) by 27.1% (71.3% vs. 44.2%) and GoogleNet-CAM (with 16.7M parameters and 13.5G MACs) by 27.2% (71.3% vs. 41.1%) in Table 3.

Error Analysis. To further reveal the effect of TS-CAM, we categorize the localization errors into five: classification error (Cls), multi-instance error (M-Ins), localization part error (Part), localization more error (More), and others (OT). Part indicates that the predicted bounding box only cover the parts of object, and IoU is less than a certain threshold. More indicates that the predicted bounding box is larger than the ground truth bounding box by a large margin. Each metric calculates the percentage of images belonging to corresponding error in the validation/test set. Table 4 lists localization error statistics of M-Ins, Part, and More. TS-CAM effectively reduces the M-Ins, Part and More errors on both benchmarks, which indicates more accurate localization maps. For CUB-200-2011, TS-CAM significantly reduces both Part and More-type errors by ~17% and ~3% compared with CAM [51] on the basis of well-designed Inception V3.

4.3. Ablation Study

Using Deit-S as the backbone, we conduct ablation studies to verify the components in TS-CAM. In Table 5, we evaluate the performance of the TS-CAM on CUB-200-2011 and observed significant improvements by TS-CAM components. TransAttention solely uses semantic-agnostic attention map \((A_s)\) for object localization, while TransCAM solely uses semantic-aware maps \((S_v)\). \(A_s\) and \(S_v\) are respectively generated by Eq. 6 and Eq. 3, and are illustrated in Fig. 3. Specifically, TS-CAM obtains gains of 12.4%, 14.1%, and 14.8% in terms of Top-1, Top-5 and Gt-Known Loc. Acc compared with TransAttention. Using the semantic-aware map, TransCAM struggles from distinguishing an object from the background due to the destruction of topology. Taking advan-

5. Conclusion

We proposed the token semantic coupled attention map (TS-CAM) for weakly supervised object localization. TS-CAM takes full advantage of the cascaded self-attention mechanism in the visual transformer for long-range feature dependency extraction and object extent localization. To solve the semantic agnostic issue of the patch tokens, we proposed to re-allocate category-related semantics for patch tokens, enabling each of them to be aware of object categories. We proposed the semantic coupling strategy to fuse the patch tokens with the semantic-agnostic attention map to achieve semantic-aware localization results. Experiments on the ILSVRC/CUB-200-2011 datasets show that TS-CAM significantly improved the WSOL performance, in striking

Why attention instead of activation? The reasons are two folds: (1) Visual transformer leverages embeddings of a low-resolution class token for image classification and cannot produce high-resolution CAM. (2) The semantic-aware maps in TS-CAM, which are calculated by re-allocating the semantics from the class token to patch tokens, fail to discriminatively activate the object regions. By visualizing the similarities among patch token embeddings \( \{t_1, ..., t_N\} \) in Fig. 9 right, we observed that the patch token embeddings are similar with each other, which implies that the activation results (semantic-aware activation maps) generated by these embeddings experience difficulty to discriminate objects from their backgrounds, Fig. 8(c).
contrast with its CNN counterpart (CAM). As the first and solid baseline with transformer, TS-CAM provides a fresh insight to the challenging WSOL problem.

A. Appendix

A.1. Additional Error Analysis

Details in Error Analysis In this sub-section, the detailed definitions in Section 4.2 (Error Analysis) of the paper are given. Specifically, classification error (Cls), multi-instance error (M-Ins), localization part error (Part), localization more error (More), and others (OT) are respectively defined as follows.

- Cls indicates the predictions which are falsely classified.
- M-Ins indicates that the prediction intersects with at least two ground-truth boxes, and IoG > 0.3.
- Part indicates that the predicted bounding box covers partial object, and IoP > 0.5.
- More indicates that the predicted bounding box is larger than the ground truth bounding box by a large margin, and IoG > 0.7.
- OT indicates other predictions that do not belong to the above mentioned cases.

where IoG and IoP are defined as intersection over ground truth box and intersection over predict bounding box, respectively (similar to IoU(intersection over Union). The five cases defined above are mutually exclusive, Algorithm A.1. Each metric calculates the percentage of images belonging to corresponding error in the validation/testing set.

Table 7 shows the complete results of the error analysis. It can be seen that TS-CAM largely reduces the classification error on both CUB-2011-200 and ILSVRC datasets. Compared with CAM, TS-CAM reduces the error rate of OT on CUB-2011-200 dataset and has comparable error rate of OT on ILSVRC dataset.

Visualization of Failure Cases Fig. 10 shows the failure cases on CUB-200-2011 test set (left) and ILSVRC validation set (right). In these cases, TS-CAM focuses on parts of the textureless objects, or highlights semantic-related background regions, which are also observed in the results of CAM [51] and TransAttention.

A.2. Performance

Complete Performance Comparison Table 8 shows more performance comparisons with state-of-the-art methods on CUB-2011-200 test set. In addition to the large improvement of localization accuracy, TS-CAM significantly outperforms the state-of-the-art methods for Top-1 and Top-5 Cls. Acc. by about 4% and 2% respectively. These results clearly demonstrate that TS-CAM takes the advantage of self-attention mechanism in visual transformer, which not only activates the full extent of objects but also obtains more discriminative image classifiers.

Table 9 shows the complete performance comparison with state-of-the-art methods on the ILSVRC validation set. It can be seen that TS-CAM outperforms the baseline method CAM with InceptionV3 backbone for Top-1 and Top-5 Cls. Acc. by about 1.0% and 0.3% respectively. TS-CAM also outperforms the state-of-the-art methods based on VGG16 [28] backbone for image classification. Compared with GC-Net [19], TS-CAM achieves worse classification performance but significantly better localization performance, which implies GC-Net suffering from poor localization ability while TS-CAM utilizing the long-range feature dependency of visual transformer and able to localize full object extent.

Ablation Study In Table 10 and Table 11, we make ablation study of the classification layer in Semantic Reallocation, Section 3.2 in the paper. We replace the convolutional layer (Conv2D) for semantic-aware map generation with a fully connected layer (FC) or a 1D convolutional layer (Conv1D). It can be seen that Conv2D achieves better performance for both classification and localization, as Conv2D
Table 7. Localization error statistics.

| Methods          | CUB-2011-200 (%) | ILSVRC (%) |
|------------------|-----------------|------------|
|                  | Cls  | M-Ins | Part | More | OT | Cls  | M-Ins | Part | More | OT |
| VGG16            | 23.28 | -     | 21.91 | 10.53 | 1.76 | 29.47 | 10.65 | 3.85 | 9.58 | 0.20 |
| InceptionV3      | 26.39 | -     | 23.09 | 5.52  | 0.64 | 26.73 | 10.36 | 3.22 | 9.49 | 0.20 |
| TS-CAM (Ours)    | 19.66 | -     | 6.30  | 2.85  | 0.01 | 25.39 | 9.13  | 3.78 | 7.65 | 0.41 |

Figure 10. Failure cases on CUB-200-2011 and ILSVRC datasets. (a) Input Image. (b) Class Activation Map (CAM). (c) TransAttention: Transformer-based Attention. (d) TS-CAM (ours). (Best Viewed in Color)

A.3. Visualization Results

Comparison of Localization Maps. Fig. 13 and Fig. 14 respectively show the additional localization results on CUB-2011-200 test set and ILSVRC validation set, where TS-CAM is able to extract the long-range feature dependency of visual transformer and localize object more accurately than CAM and TransAttention. Specifically, the highlighted regions in the localization map of TS-CAM can outline the detailed contours of objects and preserve long-range feature dependency, while CAM [51] and TransAttention fail. TransAttention highlights incorrect foreground regions due to its lack of category semantics.

Top-5 Localization Maps. Fig. 15 shows the localization maps of Top-5 scored classes. In these results, the localization maps of Top-1 scored class correctly highlight the object. We found that the most highlighted regions in the localization maps of the top-5 classes are different from each other for discriminative classification, while most of the maps highlight the similar regions since these 5 classes are semantic-similar.

Table 13. Ablation results of TS-CAM when summing attention maps($A^l_i$) from different layers on ILSVRC [26] validation set.
Figure 14. Visualization of localization maps on ILSVRC datasets. (a) Input Image. (b) Class Activation Map (CAM). (c) TransAttention: Transformer-based Attention. (d) TS-CAM (ours). (Best Viewed in Color)
Figure 15. Visualization of localization maps for top 5 scored classes. The white numbers in left-top of the localization maps are the classification scores of each class, which are predicted by TS-CAM. (Best Viewed in Color)
