THE ORDER OF ELEMENTS IN SYLOW $p$-SUBGROUPS OF THE SYMMETRIC GROUP

JAN-CHRISTOPH SCHLAGE-PUCHTA

Abstract. Define a random variable $\xi_n$ by choosing a conjugacy class $C$ of the Sylow $p$-subgroup of $S_p^n$ by random, and let $\xi_n$ be the logarithm of the order of an element in $C$. We show that $\xi_n$ has bounded variance and mean order $\frac{\log n}{\log p} + O(1)$, which differs greatly from the average order of elements chosen with equal probability.

In a sequence of papers ([2]–[8]), P. Erdős and P. Turán developed a statistical theory of the symmetric group $S_n$ on $n$ letters. Here a statistical theory describes properties of almost all elements of a sequence of groups, or statements on densities of certain elements or other associated structures, e.g. characters.

P. Turán posed the problem of developing a statistical theory for subgroups of $S_n$, in particular for Sylow subgroups. This was done by P. P. Pálfy and M. Szalay ([9], [10], [11]).

In particular, in the second of these papers they proved the following:

**Theorem 1.** Define the random variable $\zeta_n$ as follows: Choose an element $g$ of $P_n$ the Sylow $p$-subgroup of $S_p^n$, by random, and define $\zeta_n = \log p o(g)$, where $o(g)$ is the order of $g$. Then $\zeta_n$ has bounded variance, and there are positive constants $c_1, c_2$, such that $c_1 n < M_n < c_2 n$, where $M_n$ denotes the mean value of $\zeta_n$.

Recently M. Abért and B. Virág [1] showed, that the mean value is in fact asymptotically equal to $c_p n$, where $c_p$ is given as solution of the equation

$$(1 - c_p)/c_p \log(1 - c_p) + \log c_p = \log(1 - 1/p).$$

In this note the analogous question is studied, however, we choose a conjugacy class instead of an element.

Define $h_n(k)$ to be the number of conjugacy classes of $P_n$ consisting of elements of order $\leq p^k$. Our approach is based on the following Theorem, the second half of which was proven by P. P. Pálfy and M. Szalay [9].

**Theorem 2.** For $n, k \geq 1$ we have the recurrence relation

$$h_{n+1}(k) = \frac{1}{p} \left( h_n(k)p - h_n(k) \right) + h_n(k) + (p - 1)h_n(k - 1). \quad (1)$$

In particular, for $h_n(n)$, the total number of conjugacy classes, we have

$$h_n(n) = \left[ p^{\frac{n+1}{p+1}} |P_n|^{\gamma} \right] - \delta_p,$$

where $0 < \gamma < 1$ is a constant depending on $p$, and $\delta_p = 1$ if $p = 2$, and 0 otherwise.

Using this recurrence relation we will prove the following theorem. Define $\xi_n$ to be $\log p o(C)$, where $C$ is a conjugacy class chosen among the conjugacy classes of $P_n$ at random.

**Theorem 3.** The random variable $\xi_n$ has mean value $\frac{\log n}{\log p} + O(1)$ and has bounded variance.

Comparing Theorem 1 and Theorem 3, one sees that there are few conjugacy classes of order $\sim c_p n$, containing almost all elements, whereas almost all conjugacy classes are of order $\sim \frac{\log n}{\log p}$ but contain
neglectable proportion of all elements. It is interesting to note that P. Erdős and P. Turán discovered the converse phenomenon in the symmetric group $S_n$: Almost all elements of $S_n$ have order $e^{(1/2 + o(1)) \log^2 n}$, whereas almost all conjugacy classes have order $e^{(c + o(1)) \sqrt{n}}$, where $c$ is some positive constant.

To prove Theorem 2, note that $P_{n+1} = P_n \wr C_p$, where $C_p$ is the cyclic group of order $p$. To count the conjugacy classes in $P_{n+1}$, we distinguish three cases: Conjugacy classes, which are contained in the base group $P_n \times \cdots \times P_n$, and which are embedded in the diagonal of this product, conjugacy classes which are non-diagonally contained in the base group, and conjugacy classes, which are not contained in the base group. Clearly, these cases are disjoint and cover all possibilities. The conjugacy classes of the first kind correspond to conjugacy classes of $P_n$, and the action of $C_p$ leaves these conjugacy classes invariant, hence, there are $h_n(k)$ conjugacy classes of elements of order $\leq p^k$ of the first kind. There are $h_n(k)^p - h_n(k)$ conjugacy classes in $P_n \times \cdots \times P_n$ which do not contain diagonal elements, and the action of $C_p$ does not leave any such class invariant, hence, there are $\frac{1}{p} (h_n(k)^p - h_n(k))$ conjugacy classes of the second kind. To count conjugacy classes of the third kind, write an element of $P_{n+1}$ as $(f, \sigma)$, where $f : \{1, \ldots, p\} \to P_n$, and $\sigma \in C_p$. Conjugation cannot change $\sigma$, hence, the total number of conjugacy classes of the third kind equals $(p - 1)$ times the number of conjugacy classes of elements having $\sigma(1) = 2$. For an element $x \in P_n$ and an integer $i \leq p$, define the function $g$ by $g(i) = x$, $g(j) = 1$ for $j \neq i$. Then we find $(f, \sigma)(g, \text{id}) = (h, \sigma)$, where

$$h(j) = \begin{cases} f(j), & j \neq i, i + 1 \\ \sigma f(i), & j = i \\ f(i + 1)x^{-1}, & j = i + 1 \end{cases}. $$

In particular, every element of the third kind is conjugated to an element $(f, \sigma)$ with $f(i) = 1$ for all $i \neq 1$. Moreover, choosing $g(i) = x$ for all $i \in \{1, \ldots, p\}$, we find that conjugacy classes of the third kind correspond to conjugacy classes of $P_n$. Finally, the order of $(f, \sigma)$ in $P_{n+1}$ equals $\prod_{i=1}^p f(i)$ in $P_n$, hence, there are $h_n(k - 1)$ conjugacy classes of elements of order $k$ in $P_{n+1}$ of the third kind. Adding up the contribution of these three classes yields the recurrence relation (1). The formula for $h_n(n)$ follows from this by induction. A different proof of this formula counting characters was given by P. P. Pálfy and M. Szalay [9].

We begin the proof of Theorem 3 with two simple remarks: First it is obvious from the definition that for fixed $n$, $h_n(k)$ is increasing with $k$. Further note that $h_{n+1}(1) > h_n(1) + (p - 1)$, thus, for $n \nearrow \infty$, $h_n(1)$ tends to $\infty$.

We will write

$$\alpha_n(k) := \frac{h_n(k - 1)}{h_n(n)}$$

and

$$\beta_n(k) := \frac{h_n(k - 1)}{h_n(n)} \left( \frac{h_{n-1}(k)}{h_{n-1}(k - 1)} \right)^p. $$

We first collect some properties of $\alpha$ and $\beta$.

**Proposition 4.** Define $\alpha$ and $\beta$ as above, and assume that $1 \leq k \leq n$.

1. We have

$$\beta_n(k) = \frac{1 + (p - 1)h_{n-1}(k - 1)^{1-p} + p(p - 1)h_{n-1}(k - 2)h_{n-1}(k - 1)^{1-p}}{1 + (p - 1)h_{n-1}(k)^{1-p} + p(p - 1)h_{n-1}(k - 1)h_{n-1}(k)^{-p}}$$

(2)

2. We have $|\log \beta_n(k)| \ll h_{n-1}(k - 1)^{1-p}$.

3. We have

$$\alpha_n(k) = \beta_k(k)^{n-k} (\beta_k(k) \beta_{k+1}(k + 1))^{p^{n-k-1}} \cdots (\beta_n(k) \cdots \beta_n(n)).$$

4. We have $\beta_n(n) = 1 - \frac{(p-1)^n}{h_n(n)}$. Furthermore, for $p = 2$, we have

$$\beta_n(n - 1) = 1 + O \left( \frac{h_n(n-2) - 2}{h_n(n)} \right).$$
(5) As \( k \) tends to \( \infty \), the asymptotic \( \log \alpha_n(k) \approx -p^{-n-k} \frac{h_{k0}(k)}{h_k(k)} \) holds.

Before we prove this, we indicate how Theorem 3 follows from Proposition 4. Obviously, for fixed \( n \), \( \alpha_n(k) \) is increasing with \( k \), \( \alpha_n(1) = \frac{1}{h_n(n)} \to 0 \), and \( \alpha_n(n+1) = 1 \), hence, for \( n \geq 1 \) there is a unique integer \( k_0(n) \) with the property \( \alpha_n(k_0) \leq 1/2 < \alpha_n(k_0 + 1) \). By 4.5 we get

\[
- \log 2 \geq \log \alpha_n(k_0) \sim -p^{-n-k_0} \frac{(p-1)k_0}{h_{k0}(k_0)}
\]

Taking logarithms again and using the value for \( h_{k0}(k_0) \) given by Theorem 1, we get

\[
\log \log 2 \leq (1 + o(1)) \left( (n - k_0) \log p + k_0 \log(p - 1) - \frac{\gamma + 1}{p - 1} \log p - \gamma + 1 + \frac{\log(1)}{p - 1} \log p \right).
\]

From this inequality it is easy to see that \( k_0 \leq \frac{\log n}{\log p} + O(1) \). In the same way, starting from the inequality \( \alpha_n(k_0 + 1) > 1/2 \), we get \( k_0 \geq \frac{\log n}{\log p} + O(1) \), thus \( k_0 = \frac{\log n}{\log p} + O(1) \). We want to show that \( k_0 \) is close to the mean value of \( \xi_n \), and that the variance of \( \xi_n \) is bounded. Both statements follow at once, if we can show that the mean value of \( (\xi_n - k_0)^2 \) is bounded. We estimate this value as follows.

\[
E(\xi_n - k_0)^2 = \frac{1}{h_n(n)} \sum_{k=0}^{n} (h_n(k) - h_n(k-1))(k - k_0)^2
\]

\[
= \sum_{k=0}^{n} (\alpha_n(k+1) - \alpha_n(k))(k - k_0)^2
\]

\[
\leq \sum_{k=k_0+1}^{n} (\alpha_n(k+1) - \alpha_n(k))(k - k_0)^2 + \sum_{k=k_0+1}^{n} (1 - \alpha_n(k))(k - k_0)^2.
\]

To estimate these sums, we note first that \( \alpha_n(k)^2 > \alpha_n(k - 1) \) for \( k \) greater than some absolute constant, for by 4.5 we have

\[
\frac{\log \alpha_n(k-1)}{\log \alpha_n(k)} = (1 + o(1)) \frac{p}{p - 1} \frac{h_k(k)}{h_{k-1}(k-1)},
\]

and since the right hand side tends to \( \infty \), it will eventually become \( \geq 2 \). Using this fact together with the definition of \( k_0 \), we obtain the estimates

\[
\alpha_n(k_0 - d) < 2^{-2^d},
\]

\[
\alpha_n(k_0 + d) > \frac{2^d - 1}{\sqrt{2^d - 1}} = 1 - \frac{\log 2}{2^{d - 1}} + O(2^{-2d}).
\]

Hence, both sums in the estimate for \( E(\xi_n - k_0)^2 \) can be estimated by converging sums of the form \( d^2 2^{-d} \), and we obtain \( E(\xi_n - k_0)^2 \ll 1 \), which proves Theorem 3.

Therefore, it remains to prove Proposition 4.

1. In the definition of \( \beta_n(k) \), replace the values of \( h \) in the first fraction with the recurrence relation \([1]\) to obtain

\[
\beta_n(k) = \frac{h_{n-1}(k-1)p + (p-1)h_{n-1}(k-2) + p(p-1)h_{n-1}(k-1)^p}{h_{n-1}(k)^p + (p-1)h_{n-1}(k) + p(p-1)h_{n-1}(k-1)^p + (p-1)h_{n-1}(k-1)^p}
\]

\[
= \frac{1 + (p-1)h_{n-1}(k-1)^{1-p} + p(p-1)h_{n-1}(k-2)h_{n-1}(k-1)^{-p}}{1 + (p-1)h_{n-1}(k-1)^{-p} + p(p-1)h_{n-1}(k-1)^{-p}}.
\]

2. We use the \([2]\). To give an upper bound, we estimate the denominator by 1. In the numerator we replace \( h_{n-1}(k-2) \) by \( h_{n-1}(k-1) \), which increases the fraction, too. Thus we obtain the upper bound \( 1 + (p^2 - 1)h_{n-1}(k-1)^{-p} \). In the same way we obtain a lower bound, and both bounds together yield a bound for \(| \log \beta_n(k) | \).
3. This statement follows from the definition of $\alpha$ by a simple computation:

$$\frac{h_n(k-1)}{h_n(k)} = \beta_n(k) \left( \frac{h_{n-1}(k-1)}{h_{n-1}(k)} \right)^p$$

$$= \beta_n(k) \beta_{n-1}(k) \cdots \beta_k(k) p^{n-k}$$

$$\alpha_n(k) = \frac{h_n(k-1)}{h_n(k)} \frac{h_n(k)}{h_n(k+1)} \cdots \frac{h_n(n-1)}{h_n(n)}$$

$$= \left( \beta_n(k) \beta_{n-1}(k) \cdots \beta_k(k) p^{n-k} \right) \cdots \left( \beta_n(n-1) \beta_n(n-1) \cdots \beta_k(k) p^{n-k-1} \right)$$

Now rearranging terms according to the exponent proves our claim.

4. To compute $\beta_n(n)$, it suffices to compute $h_n(n-1)$. We have

$$h_n(n-1) = \frac{1}{p} \left( h_{n-1}(n-1)^p - h_{n-1}(n-1) + (p-1) h_{n-1}(n-2) \right)$$

$$= h_n(n) - (p-1) (h_{n-1}(n-1) - h_{n-1}(n-2)).$$

From this we deduce by induction that $h_n(n) - h_{n-1}(n-1) = (p-1)^{n-1} (h_1(1) - h_1(0))$. But $h_1(1) - h_1(0) = p-1$, since $P_1$ is cyclic of order $p$, and we get

$$\beta_n(n) = \frac{h_n(n-1)}{h_n(n)} = 1 - \frac{(p-1)^n}{h_n(n)}.$$

Now assume that $p = 2$. Then we have

$$h_n(n-2) = \frac{1}{2} \left( h_{n-1}(n-2)^2 - h_{n-1}(n-2) \right) + h_{n-1}(n-2) + h_{n-1}(n-3)$$

$$= \frac{1}{2} \left( h_{n-1}(n-1) - 1 \right)^2 - \left( h_{n-1}(n-1) - 1 \right) + h_{n-1}(n-1) - 1 + h_{n-1}(n-3)$$

$$= h_n(n-1) - h_{n-1}(n-1) - h_{n-1}(n-2) + h_{n-1}(n-3)$$

$$= h_n(n) - 2h_{n-1}(n-1) + h_{n-1}(n-3),$$

which implies $h_n(n) - h_{n-1}(n-2) \ll h_{n-1}(n-1)$; using this estimate to bound $h_{n-1}(n-1) - h_{n-1}(n-3)$, we obtain From this we obtain

$$h_n(n-2) = h_n(n) - h_{n-1}(n-1) + O(h_{n-2}(n-2)).$$

Now we can compute $\beta_n(n-1)$:

$$\beta_n(n-1) = \frac{h_n(n-2)}{h_n(n-1)} \left( \frac{h_{n-1}(n-1)}{h_{n-1}(n-2)} \right)^2$$

$$= \frac{h_n(n)}{h_n(n-1)} \left( \frac{h_{n-1}(n-1)}{h_{n-1}(n-2)} \right)^2 - 1 + \frac{h_{n-1}(n-1)}{h_n(n)} + O(h_{n-2}(n-2))$$

$$= 1 + O \left( \frac{h_{n-2}(n-2)}{h_n(n)} \right),$$

where in the last line we used the recurrence relation in the form

$$h_n(n) = \frac{1}{2} h_{n-1}(n-1)^2 + O(h_{n-1}(n-1)).$$
5. By 4.3 we can express \( \alpha \) in terms of \( \beta \), and then we will use 4.2 and 4.4 to estimate the resulting expression. We have

\[
\log \alpha_n(k) = p^{n-k} \log \beta_k(k) + p^{n-k-1} (\log \beta_{k+1}(k) + \log \beta_{k+1}(k+1)) + \\
\cdots + (\log \beta_n(k) + \ldots + \log \beta_n(n))
\]

(3)

The first error term is of lesser order than the main term, provided that \( k \gtrsim \infty \). Hence, the main term in (3) dominates the error terms as \( k \gtrsim \infty \). Using 4.2, we find

\[
\sum_{k=k+2}^{n} p^{n-\kappa} \sum_{\nu=\kappa}^{\kappa} \log \beta_n(\nu) \ll \sum_{k=k+2}^{n} p^{n-\kappa} \sum_{\nu=\kappa}^{\kappa} h_{\kappa-1}(\nu-1)^{-p} \ll \sum_{k=k+2}^{n} p^{n-\kappa} \frac{\kappa - k + 1}{h_{k-1}(k-1)} \ll \frac{p^{n-k}}{h_{k+1}(k-1)}.
\]

As can be seen from 4.2 and 4.3, we have \( h_n(n-2) \sim h_n(n) \) as \( n \to \infty \), hence, the last quantity is of the same order of magnitude as \( \frac{p^{n-k}}{h_{k+1}(k+1)} \), which is negligible compared to the main term provided that \( k \gtrsim \infty \). To bound the term coming from \( \kappa = k+1 \), we distinguish the cases \( p = 2 \) and \( p \geq 3 \). In the latter case, 4.2 implies that

\[
\log \beta_{k+1}(k) + \log \beta_{k+1}(k+1) \ll h_{k-1}(k) \sim \frac{1}{h_{k+1}(k+1)} + O\left(\frac{h_{k-1}(k-1)}{h_{k+1}(k+1)}\right).
\]

Since \( h_{k+1}(k+1) \gg h_k(k)^2 \gg h_{k-1}(k-1)^4 \), we obtain

\[
\log \beta_{k+1}(k) + \log \beta_{k+1}(k+1) \ll \frac{1}{h_k(k)^2} + \frac{1}{h_k(k)^{3/2}} = o(h_k(k)^{-1}).
\]

Hence, the main term in (3) dominates the error terms as \( k \gtrsim \infty \), and 4.5 is proven.
