Supplementation of lamb diets with vitamin E and rosemary extracts on meat quality parameters

Leonel N Leal, a,b* José A Beltrán, c Marc Bellés, c José M Bello, d Leo A den Hartog, a,b Wouter H Hendriks b and Javier Martín-Tereso a

Abstract

BACKGROUND: Supranutritional supplementation of lamb diets with α-tocopherol is an effective method to reduce lipid oxidation and colour deterioration in meat products. However, alternative antioxidant sources have been proposed to replace the supranutritional vitamin E applications.

RESULTS: Indoor concentrate-fed Rasa Aragonesa male lambs (n=480) were supplemented with increasing levels of all-rac-α-tocopheryl acetate (0.25, 0.5, 1.0 g kg⁻¹ compound feed), rosemary extract (0.20, 0.40, or 0.80 g kg⁻¹ compound feed), or rosemary extract embedded in a fat matrix (0.20, 0.40, or 0.80 g kg⁻¹ compound feed) for 14 days before slaughter. The longissimus thoracis et lumborum muscle from three lambs per pen (18 lambs per treatment) was modified-atmosphere packaged (70% O₂ + 30% CO₂) and maintained under retail conditions for 14 days. Supranutritional supplementation with antioxidants had no effect on average daily weight gain, feed intake, and feed efficiency. Rosemary extract supplementation (with or without fat embedment) had no effect on lipid oxidation, myoglobin forms, or colour stability parameters, regardless of the dose. All vitamin E supplementation levels significantly affected lipid oxidation, colour stability (L*, C*, and h), myoglobin forms, and meat discoloration parameters compared with non-supplemented lambs.

CONCLUSIONS: This study demonstrates that, unlike vitamin E, neither dose nor protection of the rosemary extract had an effect on lipid oxidation or meat colour stability of lambs during the 14 days of storage under retail conditions.

Keywords: vitamin E; all-rac-α-tocopheryl acetate; rosemary extract; lipid oxidation; colour; modified-atmosphere packaging

INTRODUCTION

Appearance, texture, and flavour are important quality attributes influencing the consumer’s choice to purchase meat products. In lamb meat, post-mortem biochemical changes, such as lipid oxidation, lead to off-odours and flavour development that have a negative impact on the shelf life of these products. Therefore, the possibility to extend shelf life and subsequent display time in lamb meat is a primary objective of the meat industry.

Dietary supplementation of lamb diets with vitamin E, and more specifically α-tocopherol, raises the concentrations of α-tocopherol in lamb tissues, which in turn delays lipid oxidation and improves the colour stability of the meat. The protective role of α-tocopherol against lipid oxidation in lamb meat is well established. However, there is still a debate on the minimum dose of vitamin E in lamb diets that effectively protects the meat from lipid deterioration and values ranging from 287 and 1000 mg kg⁻¹ feed have been proposed. Any recommendation on vitamin E needs to consider the wide variation of α-tocopherol concentration in feedstuffs, vitamin E status of the animal at the start of the supplementation period, length of the supplementation period, and differences in slaughter weight, and animal breed. In Mediterranean farming systems, lambs are typically weaned around 12–14 kg of body weight (BW), and afterwards fed ad libitum concentrates plus straw until they reach 22–24 kg BW. Under these conditions, Gonzalez-Calvo et al. found that a concentrate supplemented with 500 mg of vitamin E per kilogram, fed for a period of...
Dietary vitamin E and rosemary extracts on meat quality in lambs

7–14 days before slaughter, was sufficient to protect lamb meat from lipid oxidation and metmyoglobin (MetMb) formation.

Alternative antioxidant sources to vitamin E from several types of plants and plant materials have been investigated to replace vitamin E. However, to effectively replace supranutritional vitamin E applications, these plant-derived antioxidants need to be effectively absorbed, transported, and have a considerable deposition into the lamb muscle. In recent years, special attention has been given to rosemary (Rosmarinus officinalis L.) products and by-products, such as leaves, essential oils, distilled leaves, and extracts from the second distillation of rosemary leaves with different solvents. Early work from Nieto et al. found that supplementation of pregnant ewes with 100 g of rosemary leaves kilogram feed during pregnancy and lactation, improved the shelf life of lamb meat. Interestingly, two major diterpenes present in rosemary, carnosic acid and carnosol, were later identified in lamb muscle at concentrations that could potentially lead to an antioxidant and antimicrobial effect in the meat. Supplementation of pregnant ewes with 100 g of rosemary leaves kg−1 of feed via a treatment-specific experimental premix (Table 1), barley straw, and water via separated troughs. Per batch, two pens were randomly assigned to one of 10 treatments consisting of a basal compound feed (control), supplemented with increasing levels of all-rac-a-tocopheryl acetate (0.25, 0.50, or 1.0 g kg−1 compound feed), RE (Nutrox OSP; Nutrafur S.A., Murcia, Spain; 0.20, 0.40, or 0.80 g kg−1 compound feed), or the same RE embedded in a fat matrix (FRE; 0.20, 0.40, or 0.80 g kg−1 compound feed).

The different antioxidant sources were included in the compound feed via a treatment-specific experimental premix (Table 1). To produce the FRE, hydrogenated palm fatty acids (Norel, Madrid, Spain) were melted at 70 ± 2 °C. Afterwards, the RE (Nutrox OSP; Nutrafur S.A.) was added to the melted fat-embedded rosemary: standardized rosemary extract (inclusion of 25%) mixed with melting (70 °C) hydropalm (43.75%) and silica (31.25%).

Table 1. Composition of the basal diet and experimental premix

| Ingredients (g kg−1) | Control | Experimental premix | FRE |
|---------------------|---------|---------------------|-----|
| Barley              | 295     | Limestone           | 25  |
| Wheat               | 200     | Experimental premix  | 10  |
| Maize               | 200     | Sodium bicarbonate  | 7   |
| Soya oil            | 15      | Sodium chloride     | 5   |
| RE                  | 0.20    | Standard mineral and vitamin premixa | 3  |
| FRE                 | 0.40    |                     |     |
| FRE                 | 0.80    |                     |     |

a Mineral and vitamins provided: calcium 0.24 g, sodium 0.47 g, sulfur 0.23 g, manganese 30 mg, zinc 50 mg, copper 5 mg, iodine 0.5 mg, cobalt 0.5 mg, selenium 0.15 mg, iron 50 mg, vitamin A 8000 IU, vitamin D3 1600 IU, all-rac-a-tocopheryl acetate 25 mg. SE: all-rac-a-tocopheryl acetate.

b Hydropalm: hydrogenated palm fatty acids (Norel, Spain).

c Silica: silica H2O (Trouw Nutrition, Netherlands).

d Rosemary: standardized rosemary extract (Nutrafur S.A., Spain).

e Fat-embedded rosemary: standardized rosemary extract (inclusion of 25%) mixed with melting (70 ± 2 °C) hydropalm (43.75%) and silica (31.25%).

f all-rac-a-Tocopheryl acetate contains 50 g all-rac-a-tocopherol per 100 g of product (Trouw Nutrition, Netherlands).

MATERIALS AND METHODS

The animal care and slaughter procedures used met the guidelines of Council Directive 86/609/EEC (European Communities, 1986) on the protection of animals used for experimental and other scientific purposes.

Animals and diets

A total of 480 Rasa Aragonesa male lambs were used in this study (BW = 21.8 ± 1.39 kg). Every 3 weeks, lambs were purchased from local dealers and incorporated in the experiment in three separated batches of 160 animals each. Upon arrival at the commercial farm Franco y Navarro (Zaragoza, Spain), lambs were allocated based on BW to 20 concrete pens (20 m2) bedded with straw. For 14 days before slaughter, the lambs had free access to the experimental compound feed (presented as 3.5 mm diameter pellet; Table 1), barley straw, and water via separated troughs. Per batch, two pens were randomly assigned to one of 10 treatments consisting of a basal compound feed (control), supplemented with increasing levels of all-rac-a-tocopheryl acetate (0.25, 0.50, or 1.0 g kg−1 compound feed), RE (Nutrox OSP; Nutrafur S.A., Murcia, Spain; 0.20, 0.40, or 0.80 g kg−1 compound feed), or the same RE embedded in a fat matrix (FRE; 0.20, 0.40, or 0.80 g kg−1 compound feed).

The different antioxidant sources were included in the compound feed via a treatment-specific experimental premix (Table 1). To produce the FRE, hydrogenated palm fatty acids (Norel, Madrid, Spain) were melted at 70 ± 2 °C. Afterwards, the RE (Nutrox OSP; Nutrafur S.A.) was added to the melted ratemyoglobin (MetMb) formation.
hydrogenated palm fatty acids and stirred for 10 min at 70 ± 2 °C, until an homogeneous mixture was obtained. The mixture of hydrogenated palm fatty acids and RE was then added to silica (Trouw Nutrition, Amersfoort, Netherlands), stirred for 20 min and cooled at room temperature. The final product (free-flowing powder) was composed of 43.75% hydrogenated palm fatty acids, 31.25% silica, and 25.0% RE.

After 14 days of exposure to the treatment diets and following an overnight period without feed (but with free access to water), lambs from all treatments were mixed in a single group, transported in the same lorry, and slaughtered at the local abattoir (Mercazaragoza S.A., Zaragoza, Spain) within 2 h after leaving the farm.

**Meat processing and packaging**

Three lambs per pen (in total, 18 lambs per treatment) were randomly selected at the start of the experimental period for meat analysis. The carcasses were chilled for 24 h at 2 °C before being split longitudinally into two halves. The *longissimus thoracis et lumborum* (LTL) muscle from the right half was dissected, with subcutaneous fat removed, placed in bags (one muscle per bag), and transported in sealed plastic containers in darkness at 4 ± 1 °C to the Meat Quality Laboratory of the Veterinary Faculty of Zaragoza (Zaragoza, Spain).

Within 2 h after arrival, the LTL muscles were sectioned into approximately 1.5 cm thick portions, which were placed in polystyrene trays B5-37 (Aerpack), packed under modified-atmosphere packaging with 70% oxygen (O2) + 30% carbon dioxide (CO2) (Ulma Smart 500; Ulma Packaging, Guipúzcoa, Spain), and sealed with a polyethylene and polyamine laminate film. The carcasses were chilled for 24 h at 2 °C to the Meat Quality Laboratory of the Veterinary Faculty of Zaragoza (Zaragoza, Spain). The carcasses were chilled for 24 h at 2 °C before being split longitudinally into two halves. The *longissimus thoracis et lumborum* (LTL) muscle from the right half was dissected, with subcutaneous fat removed, placed in bags (one muscle per bag), and transported in sealed plastic containers in darkness at 4 ± 1 °C to the Meat Quality Laboratory of the Veterinary Faculty of Zaragoza (Zaragoza, Spain). The carcasses were chilled for 24 h at 2 °C to the Meat Quality Laboratory of the Veterinary Faculty of Zaragoza (Zaragoza, Spain). The carcasses were chilled for 24 h at 2 °C to the Meat Quality Laboratory of the Veterinary Faculty of Zaragoza (Zaragoza, Spain). The carcasses were chilled for 24 h at 2 °C to the Meat Quality Laboratory of the Veterinary Faculty of Zaragoza (Zaragoza, Spain). The carcasses were chilled for 24 h at 2 °C to the Meat Quality Laboratory of the Veterinary Faculty of Zaragoza (Zaragoza, Spain). The carcasses were chilled for 24 h at 2 °C to the Meat Quality Laboratory of the Veterinary Faculty of Zaragoza (Zaragoza, Spain).

**Physical and chemical analysis**

Colour was measured using a reflectance spectrophotometer (CM-2002; Minolta, Osaka, Japan) directly on the meat surface, after 2 h exposure to air. Each value was the mean of 10 determinations per sample. The parameters recorded according to the CIELAB system, were lightness L*, redness a*, and yellowness b*. Values of chroma C* and hue angle h were calculated as:

\[
C^* = \sqrt{(a^*)^2 + (b^*)^2}, \quad h = \tan^{-1}(b^*/a^*),
\]

expressed in degrees.

Lipid oxidation was expressed as thiobarbituric acid reactive substances (TBARS) and expressed as milligrams of malondialdehyde (MDA) per kilogram of meat, as described by Pfalzgraf et al. Briefly, 10 g of meat sample was homogenized with 10% trichloroacetic acid using an Ultra-Turrax T25 (Janke & Kunkel, Staufen, Germany). After centrifugation at 15000g for 30 min (at 10 °C) the supernatant was filtered (Filterlab, Barcelona, Spain), 2 mL of the filtrate was mixed with 2 mL of thiobarbituric acid (20 mol L⁻¹), homogenized, and incubated for 20 min (in boiling water). Absorbance was measured at 532 nm, and TBARS values were calculated from a standard curve of MDA obtained by the hydrolysis of 1,1,3,3-tetramethoxypropane (Sigma-Aldrich, Madrid, Spain). Samples were analysed in duplicate, and the results are expressed as milligrams of MDA per kilogram of meat.

Myoglobin forms (deoxygenmyoglobin, oxymyoglobin (OxyMb), and MetMb) were calculated from the reflectance curve described by Krywyicki using a wavelength of 690 nm. The reflectance at 473, 525, and 572 nm was obtained by linear interpolation, since the reflectance spectrophotometer only measures the reflectance between 400 and 740 nm at intervals of 10 nm.

The rate of meat discoloration was accessed by the parameter

\[
A_{580} - A_{530},
\]

according to the method proposed by van den Oord and Wesdorp. Oxygen saturation of myoglobin on meat surface was measured following the technique described by Tsuruga et al.

**Polyphenol analysis in feed**

Feed samples were homogenized using a blender and sieved with a no. 18 mesh (corresponding to 1 mm) to remove large particles before extraction. The phenolic compounds were extracted using methanol:water (80:20, v/v), sonicated for 5 min, and centrifuged. This procedure was repeated twice with the feed residue. The supernatants were combined and the methanol evaporated. For better chromatography resolution, the extracts were cleaned using solid-phase extraction with Oasis MAX 96-well plates (30 mg, 30 μl) from Waters (Water corporation, Massachusetts, USA), according to Vallverdú-Queralt et al.

The identification and quantification of the major phenolic compounds was performed using ultrahigh performance liquid chromatography (UHPLC; Waters Acuity Ultra Performance LC) coupled to an API 3000 triple quadrupole mass spectrometer (ABSciex) equipped with a Turbo ion spray source operating in negative mode. Separation was carried out using a BEH C18 (2.1 mm × 50 mm, 1.7 μm; Acquity UHPLC) maintained at 30 °C. Gradient elution was performed with acetonitrile with 0.1% of formic acid (v/v) and water with 0.1% of formic acid (v/v) using an increasing linear gradient flow of acetonitrile with 0.1% of formic acid (v/v) under the following conditions: 0 min, 20%; 0.5 min, 20%; 1.5 min, 30%; 2 min, 30%; 2.5 min, 50%; 3 min, 100%; 3.5 min, 100%; 3.7 min, 20%; and 4.5 min, 20%. The flow rate was 0.4 mL min⁻¹ and the injection volume was 10 μL. The identification and quantification of each compound were carried out using a mass spectrometer in multiple reaction monitoring mode. The quantification of the phenolic compounds was performed using calibration curves with analytical standards with the internal standard method. The internal standard was ethyl gallate (400 ng g⁻¹) (Extrasynthese, Genay, France) and the results are expressed as milligrams per kilogram of feed.

**Statistical analysis**

All statistical analyses were performed using SAS Studio (SAS Institute, Inc., Cary, NC, USA). Individual lamb data were summarized per pen, which was considered as the experimental unit for all of the parameters studied.

The model included the fixed effects of antioxidant supplement, display time, and the interaction between antioxidant supplementation and display time. The effect of batch (three rounds of 180 lambs each) was initially included in the statistical model as a fixed effect, but it was finally excluded as batch never reached statistical significance (P > 0.05). Therefore, the model was:

\[
Y_{ijk} = \mu + A_i + D_j + (A_i \times D_j) + e_{ijk}
\]
Dietary vitamin E and rosemary extracts on meat quality in lambs

RESULTS AND DISCUSSION

Animal performance

Data on BW, average daily weight gain, feed intake, and feed efficiency are presented in Table 2. There were no effects of either antioxidant source (vitamin E and RE) or dosage in the assessed performance parameters. These results align with previous findings in which dietary vitamin E inclusion levels up to 2.0 g kg\(^{-1}\) feed had no effect on lamb performance.\(^3,5\) Moreover, supplementation of lamb diets with rosemary diterpenes\(^17\) (0.6 g kg\(^{-1}\) diet) or rosemary essential oils\(^19\) (0.3 or 0.6 mL day\(^{-1}\)) were also found to have no effect on growth, feed intake, or efficiency.

Table 2. Productive performance of the lambs fed increasing level of all-rac-\(\alpha\)-tocopheryl acetate (SE), rosemary extract (RE), or fat-embedded rosemary extract (FRE)

where \(Y_{ijk}\) is the dependent variable, \(\mu\) is the population average, \(A_S\) is the fixed effect of antioxidant supplementation, \(D_j\) is the fixed effect of display time, \(A_S \times D_j\) is the interaction between \(A_S\) and \(D_j\), and \(e_{ijk}\) is the random error. Differences were declared significant when \(P < 0.05\). Tukey’s post hoc test was used to assess differences between mean values when \(P < 0.05\).

Polyphenol content in feeds and fat embedment

The identification and quantification of the major polyphenols present in the experimental diets are shown in Table 3. Overall, we found high concentrations of chlorogenic acid, ferulic acid, and ferulic acid-\(\beta\)-hexoside, which are commonly found in cereals,\(^3,9\) which accounted for >42% of the total polyphenol content in the experimental diets. Diets containing REs (either protected or unprotected), provided more carnosol, carnosic, and rosmarinic acid, major polyphenols present in REs,\(^34\) than the control diet. According to the information provided by the supplier, the RE contained approximately 20% diterpenes, in a ratio of 2:1 between carnosic acid and carnosol. However, RE supplementation (RE and FRE) resulted in higher concentrations of carnosol than carnosic acid in the experimental feeds. According to Jordán et al.,\(^20\) carnosol is a major component produced in the carnosic acid oxidation pathway, which could explain the high carnosol concentrations in the rosemary-supplemented diets and the relative low amounts of carnosic acid. On the other hand, the lower amounts of carnosol and carnosic acid in the experimental diets are likely explained by differences in the relative levels of their precursors in the experimental diets.

Polyphenol content in feeds and fat embedment

The identification and quantification of the major polyphenols present in the experimental diets are shown in Table 3. Overall, we found high concentrations of chlorogenic acid, ferulic acid, and ferulic acid-\(\beta\)-hexoside, which are commonly found in cereals,\(^3,9\) which accounted for >42% of the total polyphenol content in the experimental diets. Diets containing REs (either protected or unprotected), provided more carnosol, carnosic, and rosmarinic acid, major polyphenols present in REs,\(^34\) than the control diet. According to the information provided by the supplier, the RE contained approximately 20% diterpenes, in a ratio of 2:1 between carnosic acid and carnosol. However, RE supplementation (RE and FRE) resulted in higher concentrations of carnosol than carnosic acid in the experimental feeds. According to Jordán et al.,\(^20\) carnosol is a major component produced in the carnosic acid oxidation pathway, which could explain the high carnosol concentrations in the rosemary-supplemented diets and the relative low amounts of carnosic acid. On the other hand, the lower amounts of carnosol and carnosic acid in the experimental diets are likely explained by differences in the relative levels of their precursors in the experimental diets.
carnosic acid in FRE diets compared with RE diets could be associated with the extra heat treatment\(^{15}\) applied to the FRE diets during the incorporation of the RE into the melted fat (70 ± 2 °C).

### Lipid oxidation

Mean TBARS values for each dietary treatment during the 14 days of display are presented in Table 4. Lipid oxidation significantly increased with storage time in all groups (P < 0.05). Moreover, an interaction between storage time and dietary treatment was found (P < 0.001) for TBARS values. From day 7 onwards, LTL muscle from vitamin-E-supplemented lambs (irrespective of dose) presented significantly lower TBARS values than the control and RE- and FRE-supplemented lambs. Vitamin-E-supplemented lambs presented TBARS values ranging from 0.16 to 0.31 mg MDA kg\(^{-1}\) meat on day 7, whereas the remaining treatments registered TBARS values between 1.63 and 1.99 mg MDA kg\(^{-1}\) meat. With increasing storage time, the differences between the vitamin-E-supplemented lambs and the control, RE, and FRE lambs became wider. On day 14 of storage, LTL muscle from control and the rosemary-supplemented lambs (RE and FRE) presented TBARS values ranging from 3.25 to 4.00 mg MDA kg\(^{-1}\) meat, whereas vitamin-E-supplemented LTL muscles showed TBARS values from 0.39 to 0.69 mg MDA kg\(^{-1}\) meat. In concentrate-fed lambs, slaughtered at low BWs (lower than 30 kg live weight), a threshold of 1.0 mg MDA kg\(^{-1}\) meat has been proposed to be avoided for the development of off-flavours in lamb meat.\(^{16,17}\) After 7 days of storage, higher MDA values than 1.0 mg kg\(^{-1}\) meat were found in the LTL muscle from the control, FRE, and RE lambs. Interestingly, vitamin E supplementation at 0.25, 0.50 or 1.0 g kg\(^{-1}\) feed led to lower TBARS values (0.69, 0.56, and 0.39 mg MDA kg\(^{-1}\) meat) at the proposed threshold after 14 days of storage. In a similar study, Leal et al.\(^{16}\) found that a supplementation level of 0.16 g kg\(^{-1}\) feed with vitamin E (all-rac-\(\alpha\)-tocopherol acetate) for 14 days before slaughter was sufficient to maintain TBARS values below the threshold of 1.0 mg MDA kg\(^{-1}\) meat. Dietary supplementation of lamb di...

The data in the table represent the means of three trials. Values within a column with different superscripts are significantly different (P < 0.05). \(^{abxy}\) Values within a row with different superscript are significantly different (P < 0.05). SEM: standard error of the mean.

reported for individual L* coordinates, vitamin E supplementation significantly affected h development in lamb meat when compared with the control, RE-, and FRE-fed lambs. The effects on h value are clear after 9 days of display. No effect was found of RE supplementation in h values compared with the control. Chroma C* in meat, like with the L* values, was only affected by the dietary suplementations after 12 days of storage. Indeminitely from dosage, vitamin E supplementation led to a significant increase in C* values compared with the mean of control RE-, and FRE-fed lambs.

Overall, the positive effect of synthetic\(^{6,43}\) and natural\(^{6}\) vitamin E supplementation on meat colour parameters has already been described in lambs. Supplementation of lamb diets with vitamin E levels above 0.5 g kg⁻¹ feed has been associated with significant improvements in L*, \(^{39}\) C*, \(^{17}\) and h values\(^{6}\) in meat, when compared with non-supplemented lambs. However, our findings conflict with earlier studies that reported a positive effect on L*, \(^{17,38}\) C*, \(^{38}\) and h values\(^{38,44}\) in lamb meat, following a dietary supplementation with REs or their diterpenes. Like with vitamin E, for the phenolic compounds to exhibit any direct antioxidant activity post-mortem they need to be absorbed along the gastrointestinal tract, transported in the blood, and accumulated in the target tissue (such as the muscle).\(^{35}\) Therefore, factors that can affect the concentration of phenolic compounds in muscle,
such as dosage and length of the supplementation period, may explain the results in meat colour and oxidative stability of the RE- and FRE-supplemented lambs. In the current study, lambs were supplemented for 14 days with a diet containing increasing levels (0.2, 0.4 or 0.8 g kg\(^{-1}\)) of an RE (RE or FRE) that contained approximately 20% diterpenes (according to manufacturer’s specifications). In contrast, studies that reported positive effects of supplementing lamb diets with REs (or diterpenes) on meat colour stability targeted longer supplementation periods,\(^{5,6}\) higher dosages,\(^{44,46}\) and/or were performed using extracts with higher purity.\(^{17}\)

### Myoglobin oxidation and meat discoloration

The results of meat myoglobin (MetMb and OxyMb) oxidation are presented in Table 6. Overall, myoglobin oxidation outcomes are consistent with the colorimetric parameters previously discussed. Display time significantly affected all the myoglobin forms analysed (\(P < 0.01\)). Moreover, an interaction between antioxidant supplementation and storage time was found for MetMb and OxyMb (\(P < 0.001\)). Supplementation of lamb diets with vitamin E (0.25, 0.50 or 1.0 g kg\(^{-1}\) feed) was found to consistently affect MetMb and OxyMb oxidation after 12 days of storage. However, RE presentation form (RE or FRE) or dosage (0.20, 0.40 or 0.8 g kg\(^{-1}\) feed) had no effect on MetMb and OxyMb percentages in the LTL muscle when compared with the control. The effects of vitamin E supplementation on MetMb development are consistent with previous work in lambs,\(^{5,6}\) where a clear inhibitory effect of vitamin E supplementation on MetMb formation in lamb meat was reported, especially during longer display periods. Moreover, in line with the current study, Yagoubi et al.\(^{41}\) found no effect of supplementing lamb diets with rosemary leaf residues on MetMb percentages in meat displayed for 9 days. The proportion of OxyMb increased significantly in all groups (\(P < 0.01\)) until 7 days of storage and decreased thereafter until day 14 of storage. Apart from display time, supplementation of lamb diets with vitamin E (0.25, 0.50 or 1.0 g kg\(^{-1}\) feed) significantly reduced OxyMb oxidation when compared with the other treatments after 12 days of display. These findings contrast with previous work that found no effect of vitamin E supplementation on OxyMb oxidation in lambs.\(^{5,6}\) Interestingly, supplementation of lamb diets with REs (RE and FRE) had no effect on OxyMb percentages when compared with the control group. However, Yagoubi et al.\(^{41}\) found a clear reduction in OxyMb oxidation in the LTL muscle of Barbarine lambs supplemented with rosemary distillation residues for 77 days before slaughter.

Meat discoloration, as assessed by the decrease in the \(A_{580} - A_{630}\) parameter, and \(O_2\) saturation on the meat surface

**CONCLUSIONS**

This study demonstrated that feeding lambs a concentrate diet supplemented with all-rac-α-tocopheryl acetate for 14 days before slaughter resulted in a general improvement in meat oxidative and colour stability. This study demonstrates also that, unlike vitamin E, supplementation of lamb diets with an RE (dose and fat embedment) had no effect on lipid oxidation or meat colour stability of lambs during the 14 days of storage under retail conditions.

**ACKNOWLEDGEMENTS**

We gratefully acknowledge the support of Franco & Navarro S.A. (Zaragoza, Spain) and Mercazaragoza S.A. (Zaragoza, Spain). We also appreciate the technical assistance and support with the polyphenol analysis provided by Professor Rosa Maria Lamuela-Raventós, José Alvarenga, and Paola Quifer (University of Barcelona, Spain).

**CONFLICT OF INTERESTS**

The authors’ contributions are as follows: LNL was the principal investigator and contributed to the study design, data analyses, and interpretation of the findings and wrote the manuscript;
JMB contributed to the study design and data collection; JM-T, LAdH, and WHH contributed to the study design and data interpretation; JAB and MB contributed to the meat analysis and data interpretation. All authors read and approved the final version of the manuscript. WHH, JAB, and MB have no conflict of interests. LNL, JMB, JM-T, and LAdH are employed by Trouw Nutrition, an animal nutrition company.
