Changes in vasoactive pathways in congenital diaphragmatic hernia associated pulmonary hypertension explain unresponsiveness to pharmacotherapy

Daphne S. Mous, Marjon J. Buscop-van Kempen, Rene M. H. Wijnen, Dick Tibboel and Robbert J. Rottier

Abstract

Background: Patients with congenital diaphragmatic hernia (CDH) have structural and functional different pulmonary vessels, leading to pulmonary hypertension. They often fail to respond to standard vasodilator therapy targeting the major vasoactive pathways, causing a high morbidity and mortality. We analyzed whether the expression of crucial members of these vasoactive pathways could explain the lack of responsiveness to therapy in CDH patients.

Methods: The expression of direct targets of current vasodilator therapy in the endothelin and prostacyclin pathway was analyzed in human lung specimens of control and CDH patients.

Results: CDH lungs showed increased expression of both ETA and ETB endothelin receptors and the rate-limiting Endothelin Converting Enzyme (ECE-1), and a decreased expression of the prostaglandin-I2 receptor (PTGIR). These data were supported by increased expression of both endothelin receptors and ECE-1, endothelial nitric oxide synthase and PTGIR in the well-established nitrofen-CDH rodent model.

Conclusions: Together, these data demonstrate aberrant expression of targeted receptors in the endothelin and prostacyclin pathway in CDH already early during development. The analysis of this unique patient material may explain why a significant number of patients do not respond to vasodilator therapy. This knowledge could have important implications for the choice of drugs and the design of future clinical trials internationally.

Background

Pulmonary hypertension (PH) is the leading cause of morbidity and mortality in patients with congenital diaphragmatic hernia (CDH) [1]. The altered development of the pulmonary vasculature and the disordered pulmonary vascular remodeling [2] in combination with the imbalance of vasoactive mediators caused by endothelial dysfunction result in the arrest of pulmonary vascular growth in these patients. Current treatment of CDH patients is not evidence based [3] and is derived from studies in adults, leading mainly to off-label and unlicensed use of drugs. Current knowledge is based on compassionate use and case reports, while some patients with CDH were included in trials that were underpowered for definitive conclusions. Even international therapy guidelines are based on consensus only (level 3 evidence) [4]. In 2012, experts evaluated the current antenatal and postnatal management of CDH and emphasized the importance of optimal management of PH in these patients [5]. Worldwide, PH treatment is mainly directed against the receptors of the endothelin (ET) and prostacyclin (PGI2) pathways or the conversion of cyclic guanosine monophosphate (cGMP) in the nitric oxide (NO) pathway (Fig. 1a). In spite of these targeted treatments, it is still largely unknown how the different

components of these pathways are expressed in lungs of unaffected individuals and CDH patients.

Previous studies reported increased levels of both the endothelin A (ETA) and B (ETB) receptors in human CDH as well as in the nitrofen rat model [6, 7]. Endothelin-1 (ET-1) is a potent vasoconstrictor [8] and is increased in lung tissue of patients with pulmonary hypertension. Moreover, high plasma levels of circulating ET-1 associated with the severity of PH in human CDH [9]. NO reduces the affinity of the ETA receptor for ET-1 and may therefore terminate the ET-1 mediated signaling [10]. NO is synthesized by different NO synthases (NOS): endothelial NOS (eNOS), inducible NOS (iNOS) and neuronal NOS (nNOS), which are all expressed in the lung. However, only eNOS and, to some extent, iNOS, are expressed in the pulmonary vasculature and modulate pulmonary vascular tone [11, 12]. Some human and rat CDH studies showed a decrease in eNOS [13, 14]. However, we and others showed either no differences, or even an increased expression of eNOS in both human and rat CDH [15–19]. Prostacyclin (PGI2) is an important mediator of vasodilation, acting through the prostaglandin-I2 receptor (PTGIR) [20]. Several prostacyclin receptor agonists have been used in the treatment of persistent pulmonary hypertension of the newborn with variable effects [21–23]. Limited data are available about the use of these drugs in patients with CDH, but the few available case reports show contrasting results [24–26]. An overview of the current data for human and the rat model is provided (Tables 1 and 2).

Since CDH patients respond poorly to current treatment strategies, we hypothesized that these effects might be due to an aberrant expression of important vasoactive factors. Here, we are the first to analyze the expression of the direct targets of the most commonly used vasoactive factors. Here, we are the first to analyze the expression of these and other important factors of the three major vasoactive pathways. Using unique patient lung material, we show an increased expression of both endothelin receptors and the rate-limiting endothelin converting enzyme (ECE-1), as well as a decreased expression of the prostaglandin-I2 receptor in human CDH. Moreover, we found changes in the expression of these and other important factors of the pathways in rat CDH (Fig. 1b).

**Methods**

**Human lung samples**

Human lung samples were retrieved from the archives of the Department of Pathology of the Erasmus Medical Center, Rotterdam. In our high-volume, leading center of the EURO consortium [4], approximately 15 to 20 CDH patients a year are born, which ensures a large experience in the treatment of this disease. Paraﬃn-embedded lung samples, lacking severe hemorrhage or necrosis, were selected of controls, of CDH patients and of patients with lung hypoplasia or pulmonary hypertension unrelated to CDH. Only lung material of patients with a severe left-sided CDH and a survival of less than 7 h were selected to prevent secondary sequelae. Patient characteristics are described in Table 3.

**Animal model**

The well-established animal model was used, where in short pregnant Sprague-Dawley rats received either 100 mg nitrofen dissolved in 1 ml olive oil or just 1 ml olive oil by gavage on gestational age day E9.5 [27]. Nitrofen induces left-sided CDH in approximately 70% of the offspring, while all pups have pulmonary hypertension. At day E21 pups were delivered by caesarean section and euthanized by lethal injection of pentobarbital.

### Table 1 Overview of studies in human CDH

| Study (human) | Others |
|---------------|--------|
| Increased expression of ETA and ETB (protein level) | - Increased ET-1 (plasma levels and protein level) [43] |
| Increased expression of ECE-1 (protein level) | - Increased ET-1 (plasma levels) [9] |
| No differences in eNOS expression [16] | - Increased expression of eNOS in arteriolar endothelium and alveolar epithelium (protein level) [17] |
| No differences in eNOS expression (protein level) [19] | - No differences in eNOS expression (protein and RNA level) [14] |
| Decreased expression of Ptgir (protein level) | - No information about prostaglandin I2 |

### Table 2 Overview of studies in experimental rat CDH

| Study (experimental) | Others |
|----------------------|--------|
| Increased expression of ETA and ETB (RNA and protein level) and ETB (RNA level) | - Increased expression of ETA and ETB (RNA and protein level) [7] |
| Increased expression of ECE-1 (RNA level) | - Increased expression of ET-1 after 1 and 6 h of ventilation (RNA level) [18] |
| Increased expression of eNOS (RNA and protein level) | - Increased expression of eNOS (RNA and protein level) [15] |
| Increased expression of eNOS after 1 h of ventilation (RNA level) [18] | - Increased expression of eNOS after 1 h of ventilation (RNA level) [18] |
| Decreased expression of prostaglandin I2 and thromboxane (protein level) [34] | - Decreased expression of prostaglandin I2 and thromboxane (protein level) [34] |
Immunohistochemistry staining

Immunohistochemistry (IHC) was performed on 5 μm thick paraffin sections of lungs of both rats and humans according to standard protocols, using the Envision™ detection system (Dako Cytomation, Glostrup, Denmark) [28]. Briefly, sections were deparaffinized with xylene and rehydrated in gradual series of ethanol, after which antigen retrieval was performed by boiling samples in 10 mM Tris (pH 9.0), 1 mM EDTA. Primary and Horse Redox Peroxidase conjugated secondary antibodies were diluted in antibody dilution buffer (DAKO) with 0,5% Tween-20, and the peroxidase was detected with diamino-benzidine tetrahydrochloride (Fluka, Buchs, Switzerland). Validated primary antibodies used for IHC were Endothelin receptor A (ETA; 1:5000 (rat) 1:100 (human); Alamone, Jerusalem, Israel), Endothelin receptor B (ETB; 1:2500 (rat) 1:500 (human); Alamone), Endothelin Converting Enzyme (ECE-1; 1:500 (human); Abcam, Cambridge, MA, USA), endothelial nitric oxide synthase (eNOS; 1:400 (rat); Thermo Fisher Scientific, Waltham, MA, USA) and prostaglandin-I2 receptor (Ptgir; 1:1000 (rat) 1:500 (human); Cayman Chemical, Ann Arbor, Michigan, USA). Negative controls were performed by omitting the primary antibody.

Quantitative real-time polymerase chain reaction (qPCR)

RNA isolation of whole lungs of rat pups, cDNA synthesis and subsequent qPCR analysis was performed as previously described [28]. The gene-specific primers used are listed in Table 4. Actb was used as reference gene.

Statistical analyses

Data are presented as means (SD) for normally distributed variables. Univariate analyses were performed using independent samples t-tests for normally distributed variables. The analyses were performed using SPSS 21.0 for Windows (Armonk, NY, USA: IBM Corp.). All statistical tests were two-sided and used a significance level of 0.05.

Results

We analyzed the expression of receptors which are targeted during treatment, as well as other critical factors of the different vasoactive pathways, in order to unravel the unresponsiveness of CDH patients to current vaso-dilator therapies. Therefore, a unique set of lung material of CDH patients was used and the data were verified using the more dynamical nitrofen rat model.

Human

Besides the use of inhaled NO (iNO), current treatment is based on targeting the receptors in both the prostacyclin and endothelin pathway. Therefore, we analyzed the expression of the critical proteins of both pathways in human lung samples of control and CDH patients by immunohistochemistry. Human control lung samples showed little expression of the main target of the prostacyclin therapy, the important prostacyclin receptor PTGIR, in the fetal period. This sharply increased later during gestation at the preterm and term age. However this significant increase was absent in CDH (Fig. 2). The ETA receptor, which induces vasoconstriction and cell proliferation, was expressed in the small (25–50 μm)

Table 3 Patient characteristics

| Disease | GA  | Sex | Age of death | Cause of death |
|---------|-----|-----|--------------|----------------|
| Control | 18 + 0 | Male | – | Abortion |
| 24 + 6 | Female | Minutes | Prematurity |
| 26 + 5 | Female | 1 h | Prematurity |
| 33 + 0 | Male | Minutes | Developmental delay |

and larger (>50 μm) vessels as well as in the very small capillaries (<25 μm) in CDH. In contrast, the distribution of the ETA receptor in control lungs was limited to the small and larger vessels only (Arrowheads in Fig. 3a). The ETB receptor, involved in vasodilation through the release of NO and PGI2 (Fig. 1), was expressed both in the bronchial epithelium and in some of the larger vessels (>50 μm) in CDH (Arrowheads in Fig. 3a). However, the expression of ETB in control lungs was found only in the bronchial epithelium (Fig. 3a). Next, we analyzed the expression of ECE-1, a membrane-bound metalloprotease that converts big-endothelin into the biologically active compound ET1 and it is a rate-limiting factor in the ET pathway. Early during gestation, in the fetal period, ECE-1 is minimally expressed in the vessels of the human control lung samples, with an increase at preterm and term age. Increased expression of this enzyme at both fetal, preterm and term age was observed in CDH (Fig. 3b), indicating a potential increased bio-availability of active ET-1 already at the fetal stage of development.

To exclude that the differences in expression patterns of the crucial prostacyclin – and endothelin receptors and the rate-limiting factor ECE-1 was solely an effect of lung hypoplasia (LH) or PH, we performed immunohistochemistry on lungs of patients with LH and PH with other cause than CDH. The PTGIR receptor expression was reduced in both LH and PH (Fig. 4a). Increased expression of ETA was detected in the smallest vessels in lungs of both LH and PH (Arrowheads in Fig. 4b), whereas increased expression of ETB was only observed in both small and very small vessels of lungs of PH patients (Arrowheads in Fig. 4c). ECE-1 was not expressed differently in both LH and PH lung samples (Fig. 4d).

**Rat**

In order to validate these interesting human data, we evaluated the expression patterns of the proteins of these three pathways in the nitrofen rat model. This was supplemented with RNA and protein expression analysis of related factors. Real-time qPCR showed that the mRNA expression of both the Eta and Etb receptors was significantly higher in lungs of E21 pups with CDH compared to those of control pups. We also analyzed the expression of the ETA and ETB ligand, Et-1, but no significant differences were found between the groups. However, the mRNA encoding the rate-limiting factor Ece-1 was significantly increased in CDH compared to control, confirming the human data (Fig. 5a). Next, we analyzed the protein expression pattern of the ET receptors with immunohistochemistry. The ETA receptor was expressed in the small capillaries of both groups at E15 until E21 with a stronger expression level in CDH. At E21 only CDH lungs showed expression of the ETA receptor in the larger vessels (>50 μm) (Fig. 5b). The ETB receptor was expressed in the bronchial epithelium of all lungs without significant differences between control and CDH at all ages (Fig. 5c). There was a significant higher mRNA expression of eNos in CDH rats compared to control in relation to all cells as well as in relation to only the smooth muscles cells (Fig. 6a) or endothelial cells (data not shown). This increased expression was clearly detectable with immunostaining in the larger and smaller (<50 μm) vessels at E21. However, no obvious differences were noted earlier during development (E15 till E19) (Fig. 6b). Although there was no difference in expression of prostaglandin-I2 synthase (Ptgis) between control and CDH rat pups, there was a slight increase in the expression of Ptgir and the
prostaglandin-E1 receptor (Ptger1) in CDH at the mRNA level in both the whole lung as well as compared to the number of smooth muscle cells. In contrast, the expression of thromboxane synthase (Tbxas1), the enzyme converting prostaglandin H2 into thromboxane A2, which is in turn critical for vasoconstriction, was clearly reduced in CDH, whereas the thromboxane receptor (Tbxa2r) did not show significant differences (Fig. 7a). However, immunostaining showed no clear differences in expression of PTGIR in the vessels between both groups (Arrowheads in Fig. 7b).

**Discussion**
This is the first combined study showing the aberrant expression of different important factors in the endothelin, NO and PGI2 pathways in CDH patients (Fig. 1b) and human patients with LH or PH unrelated to CDH, possibly explaining why a large number of patients do
not respond to the current vasodilator therapy. We focused our research on direct targets of the most frequent used drugs to investigate the effectiveness of the current approach and combined this with the analysis of some key factors of the different pathways.

Since our unique human CDH material is scarce and a limiting factor, since only specimens of newborns who lived for a short period were analyzed to prevent secondary morphological changes, supplemental analyses were done on lung tissue of the nitrofen rat model. In line with previous studies in both human and rat, we found a significant increased expression of the ETA and ETB receptor, important targets of vasodilator therapy, in human CDH patients and the rat model [6, 7, 29]. However, we are the first to show an increased expression of the crucial ECE-1 enzyme in both human pulmonary vessels of CDH patients and whole lung homogenates of nitrofen treated rat pups. ECE-1 converts big ET-1 into the active form of ET-1 and is the rate-limiting step in the production of ET-1 [30]. Although there was no apparent difference in total ET-1

Fig. 4 Expression of prostaglandin and endothelin factors in human LH and PH patients. Representative images show expression of PTGIR (a), ETA (b), ETB (c) and ECE-1 (d) in patients with lung hypoplasia (LH) or pulmonary hypertension (PH) unrelated to CDH. The expression of ETA is increased in the smaller vessels of patients with LH and PH (b), and the expression of ETB is only increased in the vessels of patients with PH (c). ECE-1 is not differently expressed in the vessels both LH and PH lung samples (d) Scale bars represent 20 μm. Arrows indicate very small vessels. Patients: GA 38 + 3 (control), GA 41 + 0 (LH), GA 34 + 3 (PH)
in CDH pups, the higher expression of ECE-1 in lungs of CDH pups may lead to an increase in the active form of ET-1.

Previously, we and others showed no apparent differences in the NO pathway [16, 19]. In contrast to other studies [13, 14, 19, 29], we found an increased expression of eNOS in CDH rats in this study. This may be explained by the decreased NO availability, or by the process of eNOS uncoupling. In case of decreased bioavailability of the cofactor tetrahydrobiopterin (BH4), eNOS produces superoxide instead of NO [31]. This superoxide leads to oxidative stress, which has been observed in vessels of patients with PH [32]. The enhanced activation of the ETA receptor, as mentioned before, might lead to the increase in superoxide production through the induction of reactive oxygen species (ROS) and can thereby induce SMC proliferation and vasoconstriction. Thus, eNOS uncoupling leads to a reduction in NO bioavailability without a necessary change in the amount of eNOS [31]. Furthermore, we

have shown a slight increase in expression of the cGMP-specific phosphodiesterase 5 (Pde5) in the NO pathway in nitrofen treated rat pups previously. However, no differences were found in its phosphorylation or its downstream targets, protein kinase G1 (Prkg1) and Prkg2 [27].

The increased expression of PTGIR in control lungs during gestation could result from the gradual increase of placental PGI2 toward term [33]. The decreased expression in CDH may be a sign of reduced activation of this pathway. In contrast to our human results, we found no differences in the expression of Ptgir in CDH rat pups and an increase of this receptor on mRNA level. Since PGI2 is a potent vasodilator and thromboxane A2 (TXA2) a potent vasoconstrictor, the increased expression of Ptgir and decreased expression of Tbxas1 was unexpected. However, this aberrant balance between PGI2 and TXA2 in CDH was already previously described by our group [34]. We showed an increased level of 6-keto-PGF1α, the stable metabolite of PGI2, and an increased ratio of 6-keto-PGF1α and TXA2 in both lung homogenates and broncho-alveolar lavage (BAL) fluid of nitrofen treated rat pups. The discrepancy between the increased mRNA expression of Ptgir in CDH lungs and the absence of differences at the protein level is most likely caused by the difference in sensitivity between qPCRs and IHC. Furthermore, the different results in human and rat could be explained by the fact that we only used the most severe cases of human CDH where the rat model covers all cases.

Current treatment of CDH patients with PH is not evidence based [3] and most patients respond poorly to the used medication. Inhaled NO (iNO) is most commonly used as a first line drug, but its use varies significantly among different centers internationally [35]. In contrast to the promising results of iNO in patients with persist-ent pulmonary hypertension of the newborn [36], studies in CDH have failed to show its efficacy [35, 37], as no trials have been performed to evaluate the potential role of iNO specifically in CDH patients. Apart from iNO therapy there are some case reports on the use of sildenafil and prostacyclins in CDH patients with variable results [25, 26, 38, 39]. However, administration of enteral sildenafil in neonates leads to highly variable plasma concentrations because of variable gut absorption and/or limited hepatic clearance [40]. The recent availability of intravenous sildenafil may change its application [41], but solid pharmacokinetic data on optimal dosage are still to be published. Treatment with endothelin receptor antagonists is even a bigger problem since these drugs are only available in oral form, while data of its use in newborns are virtually absent concerning dosage absorption and safety. The fact that the current therapy should be considered mainly as “trial and error” and is effective in the minority of patients with CDH strengthens our results that there are possibly more pathways affected. Furthermore, the severity of PH in CDH patients has been known as an important predictor of the outcome and further evaluation of current therapies has been recommended by experts in the field [5]. Future treatment should become more personalized in this group of patients using pathway directed clinical trials and risk stratification [42].

Although the nitrofen rat model is well established, there are still differences in embryonic maturation between rat and human, which may have affected the results. Furthermore, ideally, we would like to be able to directly correlate the findings of aberrant expression of the different vasoactive pathways with the individual response of patients to specific vasoactive drugs. However, given the overall limitations of these types of studies and the lack of material of patients who did respond to one of the three therapies, this remains impossible as repeated lung biopsies would be needed to accomplish this.

Conclusions
In conclusion, our study shows the aberrant expression of specific vasodilator drug targets and crucial, rate-limiting factors in human CDH and the nitrofen rat model in both the endothelin, NO and PGI2 pathway already early during development. Since PH is still a major problem and the most important cause of morbidity and mortality in CDH patients nowadays while current treatment strategies are disappointing, a good insight in these pathways is needed for specific and patient directed targeting of pharmacotherapy.
