1. Introduction

The layered plates are commonly used in various engineering [1–4], by right of their outstanding merits, such as high strength, lightweight, and corrosion resistance. Enough bonding stiffness between adjacent members is the guarantee of mechanical performance of layered plates. In many cases, the connection between adjacent layers is not rigid, and thus, the interfacial slip often happens [5, 6]. Besides, the bond behavior in layered plates exhibits viscoelastic property, due to the use of polymer adhesive [7, 8]. As a result, the mechanical performance of the whole layered plates is time-dependent under sustained loads [9].

Although the layered plates exhibit good mechanical performance, it is necessary to reduce immediately the modulus difference between adjacent layers, which is a major cause of large interlaminar stress [10]. This requirement has led to the development of a novel material, called functionally graded (FG) materials, which can be designed to have continuous mechanical properties [11–13]. Due to its outstanding behaviors, FG materials have been applied in various areas, such as piezoelectric fiber-reinforced composite [14], heat-resistant materials [15], and nonuniform porous materials [16]. The concept of FG materials has also been introduced into the layered plates as face and/or transition layers, which can optimize the stress distribution and deformation [17, 18].

A number of works have been proposed to study the mechanical responses of layered FG plates. Gunes et al. [19] presented a backpropagation artificial neural network method for investigating the three-dimensional free vibration response of an adhesively bonded wide and narrow FG plates. Demirbas and Apalak [20] performed a thermoelastic investigation of FG circular plates with adhesive bond and gave the thermal stress and strain distributions with different gradient indexes. Based on the equivalent single-layer higher-order theory, Tornabene et al. [21] analyzed the dynamic response of anisotropic doubly curved shells with arbitrary geometry and variable thickness. According to the four-variable refined plate theory, an analytical solution was deduced by Li et al. [22] for the thermomechanical bending analysis of FG sandwich plate. Wang et al. [23] derived an analytical solution for investigating the heat transfer behavior in FG Sandwich plates. Tornabene et al. [24, 25] used the higher-order theory to study the dynamic behavior of anisotropic doubly curved shells. An extended cohesive damage model was proposed by Ghimire and Chen [26] for the analysis of geometrical ratio influences on the failure...
mechanisms of FG sandwiches, and they found that the layered core can provide significant improvements in loading capacity. On the basis of the four-variable plate theory, Trinh et al. [27] presented a Levy solution with state space concept for static, dynamic, and buckling analyses for sandwich FG plates. Khorshidi and Karimi [28] established an analytical model based on a modified shear deformation theory for flutter investigation of sandwich plates with FG face sheets under thermal condition. A full layewise method was employed by Nikbakht et al. [29] to obtain the yielding initiation of FG sandwich plates subjected to bi-sinusoidal distributed loading under general boundary conditions. Based on the first-order shear deformation theory, Tornabene [30] investigated the dynamic behavior of moderately thick functionally graded conical, cylindrical shells, and annular plates.

In the above literature, most works in regard to layered plates were based on the assumption of perfectly bonding or static slip, while the time-dependent characters resulting from viscoelastic bonding interlayers were neglected. Furthermore, the solutions based on the simplified plate theories have considerable error for thick plates.

This work proposes an efficient analytical model for investigating the time-dependent bending behavior of layered FG plates with considering viscoelastic bonding interlayer. In the analytical model, the mechanical behavior of each FG layer is expressed by the three-dimensional elasticity theory, which renounces the shear deformation assumption. Thus, it is highly accurate for structures with any thickness. The interlayer viscoelasticity is described by the generalized Maxwell model. The constitutive equations in the interlayer are simplified, and then, the analytical solutions of stresses and displacements for the layered FG plate are solved by virtue of the efficient recursive matrix method. Additionally, some examples provided by the present solution are conducted to investigate the influences of geometric and material characteristics on the time-dependent behaviors of the FG plate.

2. Efficient Analytical Model

In Figure 1, a layered FG plate formed by \( p \) FG layers bonded by viscoelastic bonding interlayer is considered, which is simply supported and bears a sustained load \( q(x,y) \) on its top. The three-dimensional size of the plate is \( a \times b \times H \), and the thicknesses for FG layer and bonding interlayer are, respectively, \( h_i \) and \( \Delta h_i \), in which the label \( i \) means the layer index. The elastic modulus of each FG layer, denoted by \( E_i(z) \), varies according to the exponential law along the thickness direction, and is expressed by

\[
E_i(z) = E_{i0} e^{k_i(z-d_i)},
\]

where \( k_i \) is the graded index and \( E_{i0} = E_i(d_i) \). The generalized Maxwell model, as shown in Figure 2, is employed to model the interlayer viscoelasticity, with time-dependent shear modulus given by

\[
G_i^*(t) = G_{i0} + \sum_{j=1}^n G_{ij} e^{(-t/\theta_{ij})},
\]

2.1. Governing Equations for a FG Layer. According to the elasticity theory, the constitutive equations for the \( i \)th \((i = 1, 2, \ldots, p) \) FG layer are

\[
\begin{align*}
\sigma_x'(z) &= \left( \lambda_i + 2G_i \right) \varepsilon_x'(z) + \lambda_i ^{e_i} \varepsilon_x'(z) + \lambda_i ^{e_i} \varepsilon_x'(z), \\
\tau_{xy}'(z) &= \lambda_i ^{e_i} \varepsilon_y'(z) + \lambda_i ^{e_i} \varepsilon_y'(z), \\
\tau_{xz}'(z) &= \lambda_i \varepsilon_z'(z) + \lambda_i ^{e_i} \varepsilon_z'(z) + \lambda_i ^{e_i} \varepsilon_z'(z), \\
\tau_{xz}'(z) &= \lambda_i ^{e_i} \varepsilon_x'(z) + \lambda_i ^{e_i} \varepsilon_x'(z) + \lambda_i ^{e_i} \varepsilon_x'(z),
\end{align*}
\]

where \( \sigma_x', \sigma_y', \sigma_z', \tau_{xy}', \tau_{xz}', \tau_{xz}' \), and \( \tau_{xz}' \) are stresses, \( \varepsilon_x', \varepsilon_y', \varepsilon_z', \varepsilon_y', \varepsilon_x', \varepsilon_y', \varepsilon_x' \), and \( \varepsilon_z' \) are strains and \( \lambda_i \) and \( G_i \) are lame parameters expressed as follows:

\[
\begin{align*}
\lambda_i(z) &= \frac{\mu_i E_i(z)}{(1 + \mu_i)(1 - 2\mu_i)} \frac{1}{1 - 2\mu_i}, \\
G_i(z) &= \frac{E_i(z)}{2(1 + \mu_i)}.
\end{align*}
\]

The strain-displacement relations are given by

\[
\begin{align*}
\varepsilon_x'(z) &= \frac{\partial u_i'}{\partial x} + \varepsilon_y'(z), \\
\varepsilon_y'(z) &= \frac{\partial v_i'}{\partial y}, \\
\varepsilon_z'(z) &= \frac{\partial w_i'}{\partial z}, \\
\varepsilon_y'(z) &= \frac{\partial u_i'}{\partial y} + \varepsilon_x'(z), \\
\varepsilon_x'(z) &= \frac{\partial v_i'}{\partial x}, \\
\varepsilon_z'(z) &= \frac{\partial w_i'}{\partial z},
\end{align*}
\]

where \( u_i', v_i', \) and \( w_i' \) represent the displacements in \( x, y, \) and \( z \) direction, respectively. The stress components of each FG layer should meet the following static equilibrium equations:

\[
\begin{align*}
\frac{\partial \sigma_x'}{\partial x} + \frac{\partial \tau_{xy}'}{\partial y} + \frac{\partial \tau_{xz}'}{\partial z} &= 0, \\
\frac{\partial \sigma_y'}{\partial y} + \frac{\partial \tau_{xy}'}{\partial x} + \frac{\partial \tau_{yz}'}{\partial z} &= 0, \\
\frac{\partial \tau_{xz}'}{\partial z} + \frac{\partial \tau_{yz}'}{\partial x} + \frac{\partial \tau_{zz}'}{\partial y} &= 0,
\end{align*}
\]

The simply supported boundary conditions can be expressed by

\[
\begin{align*}
u_i' &= w_i' = 0, & at x = 0, a, \\
u_i' &= w_i' = 0, & at y = 0, b.
\end{align*}
\]

Four steps are taken to obtain the differential equation involving displacement components. Firstly, by substituting (1) and (5) into (3) and eliminating the strain components, one has
\[
\begin{align*}
\sigma_x' &= \frac{E_i^{a,b_k}(z-\delta_z)}{(1+\mu_i)(1-2\mu_i)} \left[ (1-\mu_i) \frac{\partial u_i^j}{\partial x} + \mu_i \frac{\partial v_i^j}{\partial y} + \mu_i \frac{\partial w_i^j}{\partial z} \right], \\
\sigma_y' &= \frac{E_i^{a,b_k}(z-\delta_z)}{(1+\mu_i)(1-2\mu_i)} \left[ \mu_i \frac{\partial u_i^j}{\partial x} + (1-\mu_i) \frac{\partial v_i^j}{\partial y} + \mu_i \frac{\partial w_i^j}{\partial z} \right], \\
\sigma_z' &= \frac{E_i^{a,b_k}(z-\delta_z)}{(1+\mu_i)(1-2\mu_i)} \left[ \mu_i \frac{\partial u_i^j}{\partial x} + \mu_i \frac{\partial v_i^j}{\partial y} + (1-\mu_i) \frac{\partial w_i^j}{\partial z} \right], \\
\tau_{xy}' &= \frac{E_i^{a,b_k}(z-\delta_z)}{2(1+\mu_i)} \left( \frac{\partial u_i^j}{\partial y} + \frac{\partial v_i^j}{\partial x} \right), \\
\tau_{yz}' &= \frac{E_i^{a,b_k}(z-\delta_z)}{2(1+\mu_i)} \left( \frac{\partial v_i^j}{\partial z} + \frac{\partial w_i^j}{\partial y} \right), \\
\tau_{xz}' &= \frac{E_i^{a,b_k}(z-\delta_z)}{2(1+\mu_i)} \left( \frac{\partial w_i^j}{\partial x} + \frac{\partial u_i^j}{\partial z} \right).
\end{align*}
\]

By substituting (8) into (6) and eliminating the stress components, the governing equations only involving the displacement components are obtained:

\[
\begin{align*}
&2(1-\mu_i) \frac{\partial^2 u_i^j}{\partial x^2} + \frac{\partial^2 v_i^j}{\partial x \partial y} + \frac{\partial^2 w_i^j}{\partial x \partial z} + k_i \frac{\partial u_i^j}{\partial z} + \frac{1}{1-2\mu_i} \frac{\partial^2 v_i^j}{\partial x^2} + \frac{1}{1-2\mu_i} \frac{\partial^2 w_i^j}{\partial x \partial y} + \frac{1}{1-2\mu_i} \frac{\partial^2 v_i^j}{\partial x^2} + \frac{1}{1-2\mu_i} \frac{\partial^2 w_i^j}{\partial x \partial z} + k_i \frac{\partial u_i^j}{\partial z} = 0, \\
&\frac{1}{1-2\mu_i} \frac{\partial^2 u_i^j}{\partial x \partial y} + \frac{\partial^2 v_i^j}{\partial y^2} + \frac{2(1-\mu_i)}{1-2\mu_i} \frac{\partial^2 v_i^j}{\partial y^2} + \frac{\partial^2 w_i^j}{\partial y \partial z} + k_i \frac{\partial v_i^j}{\partial z} + \frac{1}{1-2\mu_i} \frac{\partial^2 w_i^j}{\partial y^2} + \frac{2(1-\mu_i)}{1-2\mu_i} \frac{\partial^2 w_i^j}{\partial y \partial z} + k_i \frac{\partial u_i^j}{\partial y} = 0, \\
&\frac{1}{1-2\mu_i} \frac{\partial^2 u_i^j}{\partial x \partial z} + \frac{2k_i \mu_i}{(1-2\mu_i)} \frac{\partial u_i^j}{\partial z} + \frac{1}{1-2\mu_i} \frac{\partial^2 v_i^j}{\partial y \partial z} + \frac{2k_i \mu_i}{(1-2\mu_i)} \frac{\partial v_i^j}{\partial z} + \frac{2(1-\mu_i)}{1-2\mu_i} \frac{\partial^2 w_i^j}{\partial y ^2} + \frac{2(1-\mu_i)}{1-2\mu_i} \frac{\partial^2 w_i^j}{\partial y \partial z} + k_i \frac{\partial w_i^j}{\partial z} = 0.
\end{align*}
\]

The present structural problem is displacement-based, and the stresses can be determined by (8) after the displacements are solved. The above governing equations are actually partial differential equations which can hard to be solved directly. Secondly, for simply supported boundary conditions, the displacements of each FG layer can be expanded in Fourier series as follows:

\[
\begin{align*}
\begin{bmatrix}
    u_i^j(x, y, z, t) \\
    v_i^j(x, y, z, t) \\
    w_i^j(x, y, z, t)
\end{bmatrix} &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \begin{bmatrix}
    u_{i,mn}^j(z, t) \cos(\alpha_m x) \sin(\beta_n y) \\
    v_{i,mn}^j(z, t) \sin(\alpha_m x) \cos(\beta_n y) \\
    w_{i,mn}^j(z, t) \sin(\alpha_m x) \sin(\beta_n y)
\end{bmatrix},
\end{align*}
\]

where \(\alpha_m = mn/a\) and \(\beta_n = mn/b\). Thirdly, by applying the Fourier series expansion of (10) to (9), the partial differential equations become ordinary differential equations as follows:

\[
\begin{align*}
&\frac{\partial^2 u_{i,mn}^j}{\partial z^2} + k_i \frac{\partial u_{i,mn}^j}{\partial z} - \frac{2(1-\mu_i)}{1-2\mu_i} \alpha_m^2 + \beta_n^2 u_{i,mn}^j(z, t) - \frac{\alpha_m \beta_n}{(1-2\mu_i)} \frac{\partial^{i,mn} u_{i,mn}^j}{\partial z} + \frac{\alpha_m}{(1-2\mu_i)} \frac{\partial^{i,mn} u_{i,mn}^j}{\partial z} = 0,
\end{align*}
\]
\[-\alpha_m \beta_n \frac{\partial^4 u_{i,mn}^{j,mn}(z,t)}{\partial z^4} + \frac{\partial^3 u_{i,mn}^{j,mn}(z,t)}{\partial z^3} + k_n \frac{\partial^2 u_{i,mn}^{j,mn}(z,t)}{\partial z^2} - \left( \alpha_m^2 + 2(1 - \mu_i) \beta_n^2 \right) \frac{\partial u_{i,mn}^{j,mn}(z,t)}{\partial z} + \frac{\beta_n}{\beta_n^2 - 1} \frac{\partial^2 u_{i,mn}^{j,mn}(z,t)}{\partial z^2} \right] = 0,
+ k_n \beta_n \frac{\partial^4 u_{i,mn}^{j,mn}(z,t)}{\partial z^4},
+ \frac{\partial^3 u_{i,mn}^{j,mn}(z,t)}{\partial z^3} + k_n \beta_n \frac{\partial^2 u_{i,mn}^{j,mn}(z,t)}{\partial z^2} + \frac{\beta_n}{\beta_n^2 - 1} \frac{\partial u_{i,mn}^{j,mn}(z,t)}{\partial z} = 0.
\]

At last, a fourth-order differential equation of \( w_{i,mn}^{j,mn} \) is derived out by eliminating \( u_{i,mn}^{j,mn} \) and \( v_{i,mn}^{j,mn} \) in (11):
\[
\frac{\partial^4 w_{i,mn}^{j,mn}}{\partial z^4} + 2k_n \frac{\partial^3 w_{i,mn}^{j,mn}}{\partial z^3} + (k_n^2 - 2 \alpha_m^2) \frac{\partial^2 w_{i,mn}^{j,mn}}{\partial z^2} + 2k_n \alpha_m \frac{\partial w_{i,mn}^{j,mn}}{\partial z} + \left( \alpha_m^4 + k_n^2 \alpha_m^3 \frac{\mu_i}{(1 - \mu_i)} \right) w_{i,mn}^{j,mn} = 0.
\]

The general solution of \( w_{i,mn}^{j,mn} \) is
\[
w_{i,mn}^{j,mn}(z,t) = \sum_{j=1}^{4} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t),
\]
where \( C_{i,mn}^{j,mn}(t) \) are the undetermined time-dependent coefficients, which can be obtained according to the boundary and continuity conditions in the subsequent sections; the
details of \( g_{i,mn}^{j,mn} \) are defined in Appendix A. By substituting into (13) and (11), \( u_{i,mn}^{j,mn} \) and \( v_{i,mn}^{j,mn} \) are obtained:
\[
u_{i,mn}^{j,mn}(z,t) = \sum_{j=1}^{4} f_{i,mn}^{j,mn} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) + \sum_{j=5}^{6} \frac{\alpha_m}{\beta_n} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t),
\]
where the details of \( f_{i,mn}^{j,mn} \) are listed in Appendix A. By substituting of (13), (14), and (8) into (9), the stress components involving undetermined coefficients can be written as
\[

\sigma_{x,mn}^{j,mn}(z,t) = \frac{E_0}{(1 + \mu_i)(1 - 2 \mu_i)} \left\{ \sum_{j=1}^{4} \left[ -\alpha_m (1 - \mu_i) f_{i,mn}^{j,mn} - \frac{\mu_i g_{i,mn}^{j,mn}}{\alpha_m} + \mu_i g_{i,mn}^{j,mn} \right] e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) + \sum_{j=5}^{6} \frac{\alpha_m}{\beta_n} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) \right\},
\]
\[

\sigma_{y,mn}^{j,mn}(z,t) = \frac{E_0}{(1 + \mu_i)(1 - 2 \mu_i)} \left\{ \sum_{j=1}^{4} \left[ -\alpha_m f_{i,mn}^{j,mn} - \frac{(1 - \mu_i) g_{i,mn}^{j,mn}}{\alpha_m} + \mu_i g_{i,mn}^{j,mn} \right] e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) + \sum_{j=5}^{6} \frac{\alpha_m}{\beta_n} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) \right\},
\]
\[

\sigma_{z,mn}^{j,mn}(z,t) = \frac{E_0}{(1 + \mu_i)(1 - 2 \mu_i)} \left\{ \sum_{j=1}^{4} \left[ -\alpha_m f_{i,mn}^{j,mn} - \frac{(1 - \mu_i) g_{i,mn}^{j,mn}}{\alpha_m} + \mu_i g_{i,mn}^{j,mn} \right] e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) + \sum_{j=5}^{6} \frac{\alpha_m}{\beta_n} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) \right\},
\]
\[

t_{x,y,mn}^{j,mn}(z,t) = \frac{E_0}{2(1 + \mu_i)} \left\{ \sum_{j=1}^{4} \left[ 2 \alpha_m f_{i,mn}^{j,mn} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) + \sum_{j=5}^{6} \left( \beta_n - \frac{\alpha_m}{\beta_n} \right) e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) \right\},
\]
\[

t_{x,z,mn}^{j,mn}(z,t) = \frac{E_0}{2(1 + \mu_i)} \left\{ \sum_{j=1}^{4} \left[ f_{i,mn}^{j,mn} g_{i,mn}^{j,mn} + \beta_n \right] e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) - \sum_{j=5}^{6} \alpha_m g_{i,mn}^{j,mn} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) \right\},
\]
\[

t_{y,z,mn}^{j,mn}(z,t) = \frac{E_0}{2(1 + \mu_i)} \left\{ \sum_{j=1}^{4} \left[ f_{i,mn}^{j,mn} g_{i,mn}^{j,mn} + \alpha_m \right] e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) + \sum_{j=5}^{6} g_{i,mn}^{j,mn} e^{\theta_{i,mn}^{j,mn}} C_{i,mn}^{j,mn}(t) \right\},
\]
2.2. Governing Equations for a Viscoelastic Interlayer. According to the Boltzmann superposition principle, the constitutive equations for the ith \((i = 1, 2, \ldots, p-1)\) interlayer are given by

\[
\tau_{xz}^{i+1}(x, y, t) = \int_{-\infty}^{t} G^*(t - \xi) \frac{\partial i_{xz}}{\partial \xi}(x, y, \xi) \, d\xi,
\]

\[
\tau_{yz}^{i+1}(x, y, t) = \int_{-\infty}^{t} G^*(t - \xi) \frac{\partial i_{yz}}{\partial \xi}(x, y, \xi) \, d\xi.
\]

(16)

The above convolution integral equations mean that the stress of viscoelastic interlayer depends on the total strain history, which leads to the heavy calculation and time-consuming. In the present work, they are simplified as

\[
\tau_{xz}^i(x, y, t) = G^*(t) \tau_{xz}^i(x, y, t),
\]

\[
\tau_{yz}^i(x, y, t) = G^*(t) \tau_{yz}^i(x, y, t).
\]

(17)

In comparison with the exact solution, this simplification leads to small error, and the present solution is always on the side of safety [25]. Considering that \(\Delta h\) is far less than \(h_n\), the shear strains can be assumed to be constant in \(z\) direction and given by

\[
y_{xz}^i(x, y, t) = \frac{u_{xz}^{i+1}(x, y, d_{i+1}, t)}{\Delta h} - u_{xz}^i(x, y, d_i, t),
\]

\[
y_{yz}^i(x, y, t) = \frac{v_{yz}^{i+1}(x, y, d_{i+1}, t)}{\Delta h} - v_{yz}^i(x, y, d_i, t).
\]

(18)

The shear stress continuity relationships between adjacent layers are

\[
\Phi_{mn}^{i}(z, t) = \begin{bmatrix}
\Phi_{mn,1}^{i}(z, t) & \Phi_{mn,2}^{i}(z, t) & \Phi_{mn,3}^{i}(z, t) & \Phi_{mn,4}^{i}(z, t) & \Phi_{mn,5}^{i}(z, t) & \Phi_{mn,6}^{i}(z, t)
\end{bmatrix}^T,
\]

\[
\Phi_{mn}^{i}(z, t) = \begin{bmatrix}
\Phi_{mn,1}^{i}(z, t) & \Phi_{mn,2}^{i}(z, t) & \Phi_{mn,3}^{i}(z, t) & \Phi_{mn,4}^{i}(z, t) & \Phi_{mn,5}^{i}(z, t) & \Phi_{mn,6}^{i}(z, t)
\end{bmatrix}^T,
\]

(22)

where

\[
\Phi_{mn}^{i}(d_{i+1}, t) = \Phi_{mn}^{i}(d_i, t),
\]

(24)

where

\[
\Phi_{mn}^{i+1}(x, y, d_{i+1}, t) = \Phi_{mn}^{i+1}(x, y, d_i, t).
\]

(19)

2.3. Recursive Matrix Method. The stresses on the top and bottom surfaces of the plate are

\[
\sigma_x^p(x, y, H, t) = -q(x, y),
\]

\[
\tau_{xz}^p(x, y, H, t) = 0,
\]

\[
\tau_{yz}^p(x, y, H, t) = 0,
\]

\[
\sigma_z^p(x, y, 0, t) = 0,
\]

\[
\tau_{xz}^p(x, y, 0, t) = 0,
\]

\[
\tau_{yz}^p(x, y, 0, t) = 0.
\]

(20)

Since the stresses and displacements are in series form, \(q(xy)\) should also be expanded as

\[
q(x, y) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} q_{mn} \sin(\alpha_m x) \sin(\beta_n y),
\]

(21)

By substitution of (13)–(15) into (8), the general solution of stresses and displacements can be transferred into the matrix form as

\[
\Phi_{mn}^{i}(z, t) = M_{mn}^{i}(z, t) A_{mn}^{i}(t),
\]

(22)

where

\[
M_{mn}^{i}(z) = \begin{bmatrix}
R_{mn}^{11}(z) & R_{mn}^{12}(z) & R_{mn}^{13}(z) & R_{mn}^{14}(z) & R_{mn}^{15}(z) & R_{mn}^{16}(z) \\
R_{mn}^{21}(z) & R_{mn}^{22}(z) & R_{mn}^{23}(z) & R_{mn}^{24}(z) & R_{mn}^{25}(z) & R_{mn}^{26}(z) \\
R_{mn}^{31}(z) & R_{mn}^{32}(z) & R_{mn}^{33}(z) & R_{mn}^{34}(z) & R_{mn}^{35}(z) & R_{mn}^{36}(z) \\
R_{mn}^{41}(z) & R_{mn}^{42}(z) & R_{mn}^{43}(z) & R_{mn}^{44}(z) & R_{mn}^{45}(z) & R_{mn}^{46}(z) \\
R_{mn}^{51}(z) & R_{mn}^{52}(z) & R_{mn}^{53}(z) & R_{mn}^{54}(z) & R_{mn}^{55}(z) & R_{mn}^{56}(z) \\
R_{mn}^{61}(z) & R_{mn}^{62}(z) & R_{mn}^{63}(z) & R_{mn}^{64}(z) & R_{mn}^{65}(z) & R_{mn}^{66}(z)
\end{bmatrix},
\]

(23)
By substituting $d^p_i$ and $d^b_i$ into the $z$-coordinate in (24), respectively, we obtain

$$\Phi^{i}_{mn}(d^p_i, t) = M^{i}_{mn}(d^p_i)\Lambda^{i}_{mn}(t),$$

$$\Phi^{i}_{mn}(d^b_i, t) = M^{i}_{mn}(d^b_i)\Lambda^{i}_{mn}(t).$$

Elimination of $\Lambda^{i}_{mn}(t)$ in (26) yields

$$\Phi^{i}_{mn}(d^b_i, t) = [M^{i}_{mn}(d^b_i)M^{i}_{mn}(d^b_i)^{-1}]\Phi^{i}_{mn}(d^b_i, t).$$

By reusing (24) and (27), from $i = 1$ to $i = p$, one obtains

$$\Phi^{p}_{mn}(d^p_i, t) = \prod_{i=p}^{2} [M^{i}_{mn}(d^p_i)M^{i}_{mn}(d^p_i)^{-1}\Psi(t)]M^{i}_{mn}(d^p_i)M^{i}_{mn}$$

$$\cdot \left(\frac{d^p_i}{d^p_i}\right)^{-1}\Phi^{i}_{mn}(d^p_i, t).$$

Four $3 \times 3$ submatrices are used to define the matrix multiplication in (28) as follows:

$$\left[\begin{array}{ccc}
c^{i}_{mn,11} & c^{i}_{mn,12} \\
c^{i}_{mn,21} & c^{i}_{mn,22}
\end{array}\right] = \prod_{i=p}^{2} [M^{i}_{mn}(d^p_i)M^{i}_{mn}(d^p_i)^{-1}\Psi(t)]M^{i}_{mn}$$

$$\cdot \left(\frac{d^p_i}{d^p_i}\right)^{-1}.\Phi^{i}_{mn}(d^p_i, t).$$

Thus, (28) can be written as

$$\Phi^{p}_{mn}(d^p_i, t) = \left[\begin{array}{ccc}
c^{i}_{mn,11} & c^{i}_{mn,12} \\
c^{i}_{mn,21} & c^{i}_{mn,22}
\end{array}\right] \Phi^{p}_{mn}(d^p_i, t).$$

By the decomposition of (30), two submatrix equations are given as

By solving (31), the displacement boundary value on the bottom surface of the structure can be expressed as

$$\left[\begin{array}{c}
u^{p}_{mn}(d^p_i, t) \\
u^{b}_{mn}(d^p_i, t) \\
u^{b}_{yz}(d^p_i, t) \\
u^{b}_{zx}(d^p_i, t)
\end{array}\right] = \left[\begin{array}{c}
C^{i}_{mn,11}v^{p}_{mn}(d^p_i, t) + C^{i}_{mn,12}v^{b}_{mn}(d^p_i, t) \\
C^{i}_{mn,11}u^{p}_{mn}(d^p_i, t) + C^{i}_{mn,12}u^{b}_{mn}(d^p_i, t) \\
C^{i}_{mn,11}r^{p}_{mn}(d^p_i, t) + C^{i}_{mn,12}r^{b}_{mn}(d^p_i, t) \\
C^{i}_{mn,11}\tau^{p}_{mn}(d^p_i, t) + C^{i}_{mn,12}\tau^{b}_{mn}(d^p_i, t)
\end{array}\right].$$

Similar to the relationship in (28), $\Phi^{i}_{mn}(d^p_i, t)$ for any FG layer is obtained from (24) and (27) as follows:

$$\Phi^{i}_{mn}(d^p_i, t) = \prod_{i=p}^{2} [M^{i}_{mn}(d^p_i)M^{i}_{mn}(d^p_i)^{-1}\Psi(t)]M^{i}_{mn}(d^p_i)M^{i}_{mn}$$

$$\cdot \left(\frac{d^p_i}{d^p_i}\right)^{-1}\Phi^{i}_{mn}(d^p_i, t).$$

The time-dependent coefficients of the $i$th FG layer are further obtained as

$$\Lambda^{i}_{mn}(t) = M^{i}_{mn}(d^p_i) - \prod_{i=p}^{2} [M^{i}_{mn}(d^p_i)M^{i}_{mn}(d^p_i)^{-1}\Psi(t)]M^{i}_{mn}(d^p_i)M^{i}_{mn}$$

$$\cdot \left(\frac{d^p_i}{d^p_i}\right)^{-1}\Phi^{i}_{mn}(d^p_i, t).$$

Finally, the substitution of (34) into (13)–(15) yields the solution of stress and displacement components for each FG layer.

### 3. Numerical Results and Discussion

In the following, the FG sandwich plate ($p = 3$) is taken as an example. The variables with the superscript $r$, e.g., $\sigma^r_{x}$, are defined as the result of stress or displacement at the point of $x = 0 \cdot 25a$, $y = 0 \cdot 25b$, and $z = h_i$. The variables with two vertical lines denote their absolute values, e.g., $|w_i|$.

#### 3.1. Validation of the Present Solution

The convergence property of the present solution is assessed first. The series are truncated into a finite number $M$ for actual calculations.
and the deviation of neutral plane of the FG layer. Results from the neglect of the transverse shear deformation

\[ \begin{align*}
and w_r
\end{align*} \]

Mathematical Problems in Engineering 7

1

The parameters and the convergence accuracy is four significant digits. Which are given in Table 1. Table 2 lists the present results of the viscoelastic interlayer and its viscoelastic parameters of which are given in Table 1. Table 2 lists the present results with different series terms, respectively. It is found that the present results tend to be constant as series terms increase, and the convergence accuracy is four significant digits.

The present solution is compared with the Kirchhoff–Love (KL) solution [26], respectively. The parameters in the FG plate are fixed as \( a = 1000 \text{ mm}, \ b = 800 \text{ mm}, \Delta h = 0.5 \text{ mm}, \ h_1 = h_3 = 30 \text{ mm}, \ h_2 = 40 \text{ mm}, \ E_{p0} = E_0^1 = 80 \text{ GPa}, \ E_0^2 = 40 \text{ GPa}, \ k_1 = k_3 = 0.05, \ k_2 = 0, \) and \( \mu_1 = \mu_2 = \mu_3 = \mu^* = 0.3. \) The material of polyvinyl butyral (PVB) is chosen for the viscoelastic interlayer and its viscoelastic parameters are

\[ \begin{align*}
&\text{viscoelastic interlayer } E'(t), G'(t) \text{, respectively. The parameters are taken as } \theta = \eta_i/G_i. \\
&\text{For KL solution in thin plate case with small moduli distributions along the thickness direction, are }
\end{align*} \]

3.2. Parameter Research. In this section, some examples provided by the present solution are conducted to investigate the influences of geometric and material characteristics on the time-dependent behaviors of the FG plate. Some of the parameters are fixed at \( q(x,y) = \sin(\pi x/a)\sin(\pi y/b) \text{ N/mm}^2, \ a = b = 1000 \text{ mm}, \ k_1 = k_3 = −1, \ k_2 = 0, \ E_0^2 = E_0^3 = E_0^4 = 25\text{ GPa}, \) and \( \mu_1 = \mu_2 = \mu_3 = \mu^* = 0.3; \) the viscoelastic constants are given in Table 1, while the others are variable.

Figure 4 plots the stress and displacement distribution in \( z \) direction when \( t = 1 \text{ day}, 1 \text{ year}, \) and 10 years and the corresponding results in perfectly bonded (PB) case. The constants are fixed as \( h_1 = h_2 = 20 \text{ mm}, \ h_2 = 40 \text{ mm}, \Delta h = 0.2 \text{ mm}, \) and \( k_1 = −0.05. \) It can be obtained from Figure 4 that \( |\sigma_{ij}^1|, |\tau_{xy}^1|, |\tau_{xyz}^1|, \) and \( |u^1| \) considerably increase with \( t, \) while \( |\sigma_{ij}^1| \) changes slightly with time. \( \sigma_{ij}^1 \) and \( \tau_{xy}^1 \) show zig-zag distributions, and they, in the facial layers, are obviously curve distribution, which is different from isotropic material. \( u^1 \) show a zig-zag distribution but keeps straight in each FG layer. \( \tau_{xz}^1 \) gives a multipeak distribution. Compared with the results of PB case, the maximum values of \( |\sigma_{ij}^1|, |\tau_{xy}^1|, |\tau_{xyz}^1|, \) and \( |u^1| \) increase by 200.1%, 26.2%, 200.2%, 604.7%, and 1221%, respectively, at \( t = 10 \text{ years}. \)

The effect of the graded index on the stress and displacement of the FG plate, as well as the elastic modulus distributions along the thickness direction, are illustrated in Figure 5. The parameters are taken as \( h_1 = h_2 = 10 \text{ mm}, h_2 = 30 \text{ mm}, \Delta h = 0.2 \text{ mm}, \) and \( t = 1 \text{ day}, \) and the average modulus of FG facial layer, i.e., \( (\int_0^{h_i} E^{i,k} \exp(t,\nu dy))/h_i \) \( (i = 1, 3), \) is fixed at 80 GPa. From the

Note. $M$ means the series terms.

Figure 3: Continued.
Figure 3: Relative errors of the KL solution compared with the present one for different length-to-height ratios as $k_1 = -0.03$, $-0.05$, $-0.07$, and $-0.09$ when $t = 10000$ s. Note. The errors are defined by $\left| \frac{(KL) - \text{Present}}{\text{Present}} \right| \times 100\%$. (a) $\sigma_i^x$, (b) $\tau_{i xy}$, and (c) $w^f$.

Figure 4: Continued.
Figure 4: The distribution of the stress and displacement in the thickness direction at different time periods. (a) $\sigma_x (x = 0.5a, y = 0.5b)$, (b) $\sigma_y (x = 0.5a, y = 0.5b)$, (c) $\tau_{xz} (x = 0, y = 0.5b)$, (d) $\tau_{xz} (x = 0, y = 0)$, (e) $u' (x = 0, y = 0.5b)$, and (f) $w' (x = 0.5a, y = 0.5b)$.

Figure 5: The influence of graded index on the distribution of the elastic modulus, stress, and displacement along the thickness direction with fixed material consumption. (a) $E_i(z)$, (b) $\sigma_x$, (c) $\tau_{xz}$, and (d) $w'$. 
results shown in Figures 5(b) and 5(c), the decline of $k_1$ reduces the maximum value of $|\sigma'_{x1}|$ and $|\omega'|$ but enlarges that of $|\sigma'_{1}|$. As $k_1$ goes down from 0.2 to -0.2, $|\sigma'_{x1}|$ and $|\omega'|$ fall by 10.0% and 15.7%, respectively, while $|\sigma'_{1}|$ increases by 156.7%. In the other word, the stress and displacement distribution can be optimized by adjusting the graded index.

Figure 6 shows the influences of $t$, $k_1$, and $\Delta h$ on the maximum value of the stress and displacement. The parameters are fixed at the same as those in Figure 5, except $t$, $k_1$ and $\Delta h$ are variable. It can be seen from Figure 6 that, as $k_1 = -0.1$, $|\sigma'_{x1}|$, $|\tau_{x1z}|$, and $|\omega'|$ increase monotonously and keeps invariant as $t$ or $\Delta h$ increases. Due to the increase of $t$ and $\Delta h$ resulting in a reduced shear modulus of the interlayer, and as $t \to \infty$, $G^* (t)$ approaches the fixed value $G^*$. Similarly, $|\tau_{x1z}|$ and $|\omega'|$ increase monotonously and tend to definite values with the increase of $k_1$ or $t$ as $\Delta h = 0.2$ mm, which results from that the difference in elastic modulus between the adjacent layer surfaces grows gradually as $k_1$ increases. For a given $t$, $|\sigma'_{x1}|$ decreases first and then increases as $k_1$ grows, which is owing to the fact that the location of $|\sigma'_{x1}|$ transfers from the outer surface of the facial layer to the inner surface in the early stage, while in the medium or long term, the location of

---

**Figure 6**: The influence of time and graded index or the interlayer thickness on the maximum value of the normal stress, shear stress, and deflection. (a) $|\sigma'_{x1}|$ (where $\Delta h = 0.2$ mm), (b) $|\sigma'_{x1}|$ ($k_1 = -0.1$), (c) $|\tau_{x1z}|$ (where $\Delta h = 0.2$ mm), (d) $|\tau_{x1z}|$ ($k_1 = -0.1$), (e) $|\omega'|$ (where $\Delta h = 0.2$ mm), and (f) $|\omega'|$ ($k_1 = -0.1$).
where
\[
\begin{align*}
\phi_{mn} &= \sqrt{\sigma_m^2 + \beta_n^2}, \\
r_{mn,1}^i &= k_i^2 \mu_i - \frac{1}{8} k_i^2 + \frac{1}{2} \beta^2_n - \frac{1}{2} \sigma_m^2, \\
r_{mn,2}^i &= k_i^2 + 4 \sigma_m^2 + 4 \beta_n^2, \\
r_{mn,3}^i &= \sqrt{k_i^2 \mu_i (\sigma_m^2 + \beta_n^2)} (\mu_i - 1), \\
T_{mn}^i &= 128 \mu_i (\mu_i - 1) k_i^2 \sigma_m \left( k_i^2 \mu_i - k_i^2 \mu_i - \frac{1}{8} \phi_{mn}^2 \right).
\end{align*}
\]
B. Details of Elements in Coefficient Matrix

$M'_{m}(z)$ in (22) is with the following nonzero elements:

\[
\begin{align*}
R_{11}^{11}(z) &= e^{\alpha_1 z}, & R_{11}^{12}(z) &= e^{\alpha_2 z}, & R_{11}^{13}(z) &= e^{\alpha_3 z}, & R_{11}^{14}(z) &= e^{\alpha_4 z}, & R_{11}^{15}(z) &= e^{\alpha_5 z}, & R_{11}^{16}(z) &= e^{\alpha_6 z}, \\
R_{21}^{11}(z) &= \frac{\beta_1}{\alpha_1} e^{\alpha_1 z}, & R_{21}^{12}(z) &= \frac{\beta_2}{\alpha_1} e^{\alpha_2 z}, & R_{21}^{13}(z) &= \frac{\beta_3}{\alpha_1} e^{\alpha_3 z}, & R_{21}^{14}(z) &= \frac{\beta_4}{\alpha_1} e^{\alpha_4 z}, & R_{21}^{15}(z) &= \frac{\beta_5}{\alpha_1} e^{\alpha_5 z}, & R_{21}^{16}(z) &= \frac{\beta_6}{\alpha_1} e^{\alpha_6 z}, \\
R_{31}^{11}(z) &= \frac{\beta_1}{\alpha_1} e^{\alpha_1 z}, & R_{31}^{12}(z) &= \frac{\beta_2}{\alpha_1} e^{\alpha_2 z}, & R_{31}^{13}(z) &= \frac{\beta_3}{\alpha_1} e^{\alpha_3 z}, & R_{31}^{14}(z) &= \frac{\beta_4}{\alpha_1} e^{\alpha_4 z}, & R_{31}^{15}(z) &= \frac{\beta_5}{\alpha_1} e^{\alpha_5 z}, & R_{31}^{16}(z) &= \frac{\beta_6}{\alpha_1} e^{\alpha_6 z}, \\
R_{41}^{11}(z) &= \frac{\beta_1}{\alpha_1} e^{\alpha_1 z}, & R_{41}^{12}(z) &= \frac{\beta_2}{\alpha_1} e^{\alpha_2 z}, & R_{41}^{13}(z) &= \frac{\beta_3}{\alpha_1} e^{\alpha_3 z}, & R_{41}^{14}(z) &= \frac{\beta_4}{\alpha_1} e^{\alpha_4 z}, & R_{41}^{15}(z) &= \frac{\beta_5}{\alpha_1} e^{\alpha_5 z}, & R_{41}^{16}(z) &= \frac{\beta_6}{\alpha_1} e^{\alpha_6 z}, \\
R_{51}^{11}(z) &= \frac{\beta_1}{\alpha_1} e^{\alpha_1 z}, & R_{51}^{12}(z) &= \frac{\beta_2}{\alpha_1} e^{\alpha_2 z}, & R_{51}^{13}(z) &= \frac{\beta_3}{\alpha_1} e^{\alpha_3 z}, & R_{51}^{14}(z) &= \frac{\beta_4}{\alpha_1} e^{\alpha_4 z}, & R_{51}^{15}(z) &= \frac{\beta_5}{\alpha_1} e^{\alpha_5 z}, & R_{51}^{16}(z) &= \frac{\beta_6}{\alpha_1} e^{\alpha_6 z}, \\
R_{61}^{11}(z) &= \frac{\beta_1}{\alpha_1} e^{\alpha_1 z}, & R_{61}^{12}(z) &= \frac{\beta_2}{\alpha_1} e^{\alpha_2 z}, & R_{61}^{13}(z) &= \frac{\beta_3}{\alpha_1} e^{\alpha_3 z}, & R_{61}^{14}(z) &= \frac{\beta_4}{\alpha_1} e^{\alpha_4 z}, & R_{61}^{15}(z) &= \frac{\beta_5}{\alpha_1} e^{\alpha_5 z}, & R_{61}^{16}(z) &= \frac{\beta_6}{\alpha_1} e^{\alpha_6 z}, \\
\end{align*}
