Pair component categories for directed spaces

Martin Raussen

Abstract

The notion of a homotopy flow on a directed space was introduced in Raussen (Appl Categ Struct 15(4):355–386, 2007) as a coherent tool for comparing spaces of directed paths between pairs of points in that space with each other. If all directed maps along such a 1-parameter deformation preserve the homotopy types of path spaces, such a flow and the parameter maps are called inessential. For a directed space, one may consider various categories whose objects are pairs of reachable points to which a functor associates the space of directed paths between them. The monoid of all inessential maps acts on such a category by endofunctors leaving the associated path spaces invariant up to homotopy. We construct a pair component category as quotient category: it has as objects pair components along which the homotopy type is invariant—for a coherent and transparent reason. This paper follows up Fajstrup et al. (J Homotopy Relat Struct 12(1):81–108, 2004); Goubault and Haucourt (Appl Categ Struct 15(4):387–414, 2007); Raussen (Appl Categ Struct 15(4):355–386, 2007) and removes some of the restrictions for their applicability. At least in several examples, it gives reasonable results for spaces with non-trivial directed loops. If one uses homology equivalence instead of homotopy equivalence as the basic relation, it yields an alternative to computable versions of “natural homology” introduced in Dubut et al (in: Automata, languages, and programming. 42nd International Colloquium, ICALP 2015, Kyoto, Japan, July 6–10, 2015. Proceedings. Part II, 171–183, Springer, Berlin 2015) and elaborated in Dubut (Directed homotopy and homology theories for geometric models of true concurrency. École normale supérieure Paris-Saclay 2017). It refines, for good and for evil, the stable components introduced and investigated in Ziemiański (Appl Categ Struct 27:217–244, 2019).
1 Introduction

1.1 Directed spaces and spaces of directed paths

A directed space (or d-space for short) (Grandis 2003, 2009) is a topological space $X$ together with a subset $\vec{P}(X) \subset P(X) = X^I$ of directed paths (or d-paths) satisfying reasonable properties: $\vec{P}(X)$ includes all constant paths, it is closed under concatenation $\alpha \ast \beta$ of d-paths $\alpha$ and $\beta$ and under non-decreasing reparametrizations. The set $\vec{P}(X)$ is given the compact-open topology inherited from $P(X) = X^I$.

A map $f : X \to Y$ is a d-map if $f(\vec{P}(X)) \subset \vec{P}(Y)$.

Particularly important d-spaces are the directed interval $\vec{I}$ with $\vec{P}(\vec{I})$ consisting of all non-decreasing maps $I \to I$ and the d-spaces $\vec{I}^n$ which are the building blocks for cubical complexes - the geometric realizations of pre-cubical sets with d-paths that are cubewise non-decreasing. Cubical complexes are the underlying d-spaces for Higher Dimensional Automata, models for true concurrency introduced and investigated by Pratt and van Glabbeek (Pratt 1991; van Glabbeek 1991, 2006); cf Sect. 3.3.1 for details.

For two points $x, y \in X$, we consider the subspace $\vec{P}(X)_{xy} \subset \vec{P}(X)$ of all d-paths with source $x$ and target $y$. The point $y$ is reachable from $x$ if this subset is non-empty; and $(x, y)$ is then called a reachable pair. A d-path $p$ and a reparametrization $q = p \circ \varphi$ with $\varphi : \vec{I} \to \vec{I}$ a surjective non-decreasing map are reparametrization equivalent. The symmetric and transitive closure of this relation is called reparametrization equivalence (Fahrenberg and Raussen 2007). Equivalence classes, the so-called traces, are the elements of trace spaces $\vec{T}(X)_{xy}$ with the quotient topology under the natural projection $p : \vec{P}(X)_{xy} \to \vec{T}(X)_{xy}$. In many cases, and in particular for cubical complexes $X$, these projection maps are homotopy equivalences (Raussen 2009).

Unlike in classical topology, the topology of path and trace spaces may vary depending on the pair of end points, even for path-connected spaces, since the reverse path of a d-path is, in general, not a d-path; for simple examples cf Sect. 4. In this article, we will partition, not the d-space $X$ itself (this was done in Fajstrup et al. (2004) and Goubault and Haucourt (2007)), but the subspace $X^2_{\vec{xy}} \subset X \times X$ of reachable pairs (cf Sect. 2.1.3) into coherent “components” along which the homotopy type of the path and trace spaces have to be invariant.

1.2 A motivating example

Reading the impressive and comprehensive thesis (Dubut 2017) by Jérémy Dubut, an example (p. 162) with graphical representation in Fig. 1 caught my attention:
The cubical complex $D$ (geometric realization of a pre-cubical set, cf Sect. 3.3.1, Definition 5) consists of four 2-cells $A$, $B_1$, $B_2$, $C$. Remark that the cell $C$ shares a face with both cells $B_1$ and $B_2$. As a result, path spaces between points in cell $A$ and points in cell $C$ have different homotopy types depending on their relative positions: The space $\overrightarrow{P}(D)_{[A,(x_1,x_2)]}$, $0 \leq x_1, y_1 \leq 1$, is empty if $x_1 > y_1$ and $x_2 > y_2$; has two contractible components if $x_1 \leq y_1$ and $x_2 \leq y_2$; is contractible else;

cf Fig. 2.

Observe that a d-path with source in $[C,(y_1,y_2)]$ and target in $[C,(y'_1,y'_2)]$ hence does not induce a homotopy equivalence between $\overrightarrow{P}(D)_{[A,(x_1,x_2)]}$ and $\overrightarrow{P}(D)_{[A,(x'_1,x'_2)]}$ by extension if $y_1 < x_1 \leq y'_1$ and $x_2 \leq y_2$ (or if $y_2 < x_2 \leq y'_2$ and $x_1 \leq y'_1$); cf Fig. 2. In particular, the only d-paths $\sigma$ within $D$ that, by extension, induce homotopy equivalences on all non-empty path spaces $\overrightarrow{P}(D)_{[A,(x_1,x_2)]}$ are the trivial ones: $y_1 = y'_1$, $y_2 = y'_2$; cf Fig. 3. Similarly for d-paths connecting different points within $A$; they are never weak isomorphisms in the parlance of Goubault and Haucourt (2007) and Fajstrup et al. (2016). As a consequence, the fundamental category $\overrightarrow{\pi}_1(D)$ of the cubical complex $D$ (cf Sect. 2.1.2) allows only a trivial system of weak isomorphisms (consisting solely of the constant paths).

### 1.3 Previous work

In order to obtain discrete invariants, previous work (Goubault and Haucourt 2007; Fajstrup et al. 2016) studies localizations and component categories (cf Sect. 2.3) of the fundamental category $\overrightarrow{\pi}_1(X)$ (cf Sect. 2.1.2) of a d-space without non-trivial loops. So-called weak isomorphisms consisting of inessential d-paths (inducing equivalences on all non-empty path spaces) form systems of morphisms that are used for localizations or quotients.

In Dubut’s example in the previous section, it turns out that each component consists of a single point only; the components do not give rise to any state space reduction at
all! Ziemiański (Ziemiański 2019) has recently suggested so-called stable components to overcome this problem, cf also Sect. 6.2.

A similar problem has been known for a long time for directed spaces with non-trivial directed loops. The simplest such space $X = S^1$, the directed circle with counterclockwise directed paths, does not allow any non-trivial paths giving rise to weak isomorphisms either, cf (Fajstrup et al. 2016, Section 6.4.1).
1.4 Contributions

The present paper takes a different approach resulting in reasonable finite component categories in both above mentioned cases (cf Sects. 4.4.1, 5.5); in particular, this is probably the first definition of a component category that can deal with directed spaces containing non-trivial directed loops.

The category of departure is no longer the fundamental category \( \pi_1^{-\to} (X) \) (with point as objects, cf Sect. 2.1.2) but its extension category \( \pi_1^{-\to} (X) \) that has \( \text{pairs} \) of reachable points within \( X^2 := \{(x, y) \in X \times X | \overrightarrow{P}(X)_X \not= \emptyset \} \) as objects; the morphisms are pairs of d-homotopy classes of d-paths, cf. Sect. 2.1.3. This category comes with a trace functor \( \pi_1^{-\to} (X)^\ast \rightarrow \pi_1^{-\to} (X) \rightarrow \text{Ho} \rightarrow \text{Top} \) (cf Sect. 2.3.2) associating to a pair \( (x, y) \in X^2 \) the trace space \( \pi_1^{-\to} (X)^y_x \). The aim is to identify, in a functorial way, pairs and d-homotopy classes in the extension category that give rise to the same data under \( \pi_1^{-\to} (X)^y_x \), up to (homotopy) equivalence.

The resulting component categories are results of a quotient formation that arises from an action of a submonoid of the monoid \( \overrightarrow{C}(X, X) \) consisting of all d-maps from \( X \) into itself. A d-map \( f : X \rightarrow X \) is called inessential if it is d-homotopic to the identity map \( id_X \) via a d-homotopy \( H \) (called a homotopy flow) that, moreover, is path space preserving (psp), ie it induces homotopy equivalences \( \pi_1^{-\to} (H_t) : \pi_1^{-\to} (X)^y_x \rightarrow \pi_1^{-\to} (X)^{H_t(y)}_{H_t(x)} \), \( t \in I, x, y \in X \), on non-empty trace spaces, cf Sect. 2.2.1, Definition 2.

These inessential d-maps act on the extension category \( \pi_1^{-\to} (X) \) by endo-functors. In particular, the trace functor \( \pi_1^{-\to} (X)^\ast \rightarrow \pi_1^{-\to} (X) \rightarrow \text{Ho} \rightarrow \text{Top} \) factors over the action of these inessential morphisms (up to isomorphisms). The arising components (objects in a component category) are the path components among the pairs of reachable points with respect to the effects of path space preserving homotopy flows on the end points: In which ways can a pair of source and target points be perturbed by a 1-parameter deformation of the entire d-space without changing the homotopy type (or another reasonable invariant) of the path space inbetween?

To construct the pair component category, we make use of a localization and quotient process (cf Sect. 2.3) on a category with objects \( X^2 \) and morphisms generated freely by those in \( \pi_1^{-\to} (X) \) and, additionally, morphisms arising from the endo-functors induced by inessential d-maps on \( X \)—modulo several natural relations; for details cf Sects. 2.1.5 and 2.3.1.

Several important properties of the arising pair component categories are collected in Sect. 3. In Sect. 4, they are used in the investigation of a number of basic examples illustrating scope and results of the chosen approach. In particular, the pair component category of the directed circle \( S^1 \) has two objects: the diagonal and its complement. Morphisms between them correspond either to the natural numbers \( \mathbb{N} \) or to the augmented natural numbers \( \mathbb{N}_{\geq 0} \), cf Sect. 4.4.1.

It is certainly out of scope to determine pair components of a general d-space and their category algorithmically. When the space in question is a cubical complex, ie the geometric realization of a pre-cubical set, (Sect. 3.3.1), it is possible to find an approximation in the form of a so-called order component category, cf Sect. 5; usually
much finer than the pair component category discussed previously: One considers only specific inessential d-maps (for details cf Sect. 5) that preserve each cell of the complex. We verify that, for a cubical complex with finitely many cells, the localization and the quotient process, as above, using only these specific d-maps, gives rise to a finite order component category. The pair component categories of cubical complexes are quotients of these order component categories.

Some of the constructions in this paper are borrowed from Raussen (2007) and developed to suit new purposes. The reader should also compare Ziemianski’s recent interesting paper (Ziemiański 2019) defining and investigating stable components. Comments can be found in Sect. 6.2. Pointers to future work, in particular investigating how far this approach can be made functorial, conclude this article in Sect. 6.3.

2 Categorical constructs. Towards components and their categories

2.1 A zoo of categories

2.1.1 Trace category

The trace category (Raussen 2007) $\vec{T}(X)$ of a d-space $X$ has as objects the elements of $X$. Morphisms from $x$ to $y$ are given by $\vec{T}(X)(x, y) := \vec{T}(X)_{x}^{y}$. Identities are given by constant traces, and composition by concatenation (up to reparametrization; hence associative). The trace category is enriched in Top.

A d-map $f : X \to Y$ between two d-spaces $X$ and $Y$ induces a functor (of topologically enriched categories) $\vec{T}(f) : \vec{T}(X) \to \vec{T}(Y)$.

2.1.2 Fundamental category

The fundamental category $\vec{π}_1(X)$ (Grandis 2003; Fajstrup et al. 2006; Grandis 2009; Fajstrup et al. 2016) of a d-space $X$ is an ordinary category. It arises from the trace category by identifying morphisms (ie traces) that are related by a directed homotopy (or a d-homotopy Grandis 2003, 2009; this is not always the same notion!). Morphisms are identified along the path-component functor $π_0 : \text{Top} \to \text{Set}$, giving rise to a quotient functor $\vec{π}_0 : \vec{T}(X) \to \vec{π}_1(X)$. A d-map $f : X \to Y$ induces a functor $\vec{π}_1(f) : \vec{π}_1(X) \to \vec{π}_1(Y)$.

2.1.3 Extension and factorization categories

Since we are interested in path spaces between given end points and their inter-relation, we need a category allowing for bookkeeping of both start and end points. The reachable pairs in a d-space $X$, ie those in $\vec{π}_2 := \{(x, y) \in X \times X| \vec{P}(X)(x, y) \neq \emptyset\}$, form the objects of the extension category $\vec{E}(X)$ (called preorder category $\vec{D}(X)$ in Raussen (2007)); cf. also Mitchell (1972), Dubut et al. (2015) and Dubut (2017) of the trace category $\vec{T}(X)$ (cf 2.1.1). It is considered as a full subcategory of $\vec{T}(X)^{op} \times \vec{T}(X)$; an (extension) morphism has the form $(\alpha*, *\beta) \in \vec{E}(\vec{T})(X)$:

$\square$ Springer
from the functor $\rightarrow$ of homotopy types (cf Sect. 2.3.2).

It was remarked by Fajstrup and Hess that it is important to consider these categories together with the subcategories which allow only right, resp. only left extensions in order to distinguish clearly different d-spaces (for example the one arising by reversing all arrows from the original one); for a careful analysis, consult (Calk et al. 2020).

The extension category comes equipped with a functor $\overrightarrow{T}(X)_*^* : \overrightarrow{T}(X) \rightarrow \text{Top}$ with $\overrightarrow{T}(X)_*^*(x, y) := \overrightarrow{T}(X)_x^y$ and $\overrightarrow{T}(X)_*^*(\alpha, \beta) = \alpha \gamma \beta$.

More useful in the future is the extension category $\overrightarrow{\pi}_1(X)^* : \overrightarrow{\pi}_1(X) \rightarrow \text{Ho - Top}$ into the category of homotopy types (cf Sect. 2.3.2).

A d-map $f : X \rightarrow Y$ between d-spaces induces a functor $\overrightarrow{\pi}_1(f) : \overrightarrow{\pi}_1(X) \rightarrow \overrightarrow{\pi}_1(Y)$ and a natural transformation $\overrightarrow{\pi}_1(f)^*\overrightarrow{T}(X)_*^* \rightarrow \overrightarrow{T}(Y)_*^* \circ \overrightarrow{\pi}_1(f)$ on $\overrightarrow{T}(X)$. Likewise a functor $\overrightarrow{\pi}_1(f) : \overrightarrow{\pi}_1(X) \rightarrow \overrightarrow{\pi}_1(Y)$ and a natural transformation $\overrightarrow{\pi}_1(f)^*\overrightarrow{T}(X)_*^* \rightarrow \overrightarrow{T}(Y)_*^* \circ \overrightarrow{\pi}_1(f)$ on $\overrightarrow{T}(X)$.

Homotopy groups (of path spaces) require a base point. To allow the necessary categorical bookkeeping, one may consider the factorization categories of the trace category, resp. the fundamental category, with traces, resp. d-homotopy classes of such as objects; cf (Raussen 2007; Dubut 2017; Calk et al. 2020). Although not essentially more difficult, we will not use factorization categories in the subsequent parts of this paper.

2.1.4 Endo-d-category

We will need further categories with the same objects (the set $\overrightarrow{\pi}_1(X)$ of reachable pairs) but with different morphisms:

**Definition 1** Let $X$ denote a topological space.

1. $C(X, X)$ denotes the topological monoid of all continuous self (or endo)-maps on $X$, equipped with the compact-open topology.
2. If $X$ is a d-space, a d-map $f \in C(X, X)$ is called an endo-d-map. Altogether, the endo-d-maps on $X$ form the topological submonoid $\overrightarrow{C}(X, X) \subset C(X, X)$ (under composition).
3. Endo-d-maps give rise to the morphisms of the category $d(X)$ with objects in $\overrightarrow{\pi}_1(X)$, i.e., $d(X)((x, y)), (x', y'))$ is the space of all d-maps $f \in \overrightarrow{C}(X, X)$ satisfying $fx = x'$ and $fy = y'$. Composition is given by composition of d-maps; the identity map $id_X$ gives rise to all identity morphisms.
The category $d(X)$ is topologically enriched.
Remark that also the endo-d-category comes with a functor $d(X)_*: d(X) \to \mathbf{Top}$; on the objects, it is defined as for the extension category; on morphisms, it associates to $f: (x, y) \to (fx, fy)$ the map $\overrightarrow{T}(f): \overrightarrow{T}(X)_X^y \to \overrightarrow{T}(X)_X^{fx}$, $[\sigma] \to [f \circ \sigma]$. In general, a d-map between d-spaces $X$ and $Y$ does not induce a functor from $d(X)$ into $d(Y)$.

2.1.5 d-extension category

Combining the morphisms from the categories $d(X)$ and $E \to \pi_1(X)^x$ yields the d-extension category of $X$: The set of objects is again the set of reachable pairs in $X^2$. The morphisms arise from a quotient of the category freely generated by the morphisms from $d(X)$ and from $E \to \pi_1(X)^x$ by composition modulo the congruence relation making diagrams (2) and (3) below commute:

$$\begin{align*}
(fx, fy) \xrightarrow{((f \circ \sigma)_*, *(f \circ \tau))} (fx', fy'), \\
(fx, fy) \xrightarrow{(\sigma_*, \tau)} (f, f)
\end{align*}$$

(2)

for any $f \in \overrightarrow{C}(X, X), (x, y) \in X^2, \sigma \in \overrightarrow{\pi_1}(X)^x_\sigma, \tau \in \overrightarrow{\pi_1}(X)^y_\tau$; and

$$\begin{align*}
(fx, fy) \xrightarrow{H(x)_*} (fx, gy), \\
(fx, fy) \xrightarrow{H(y)_*} (gx, gy)
\end{align*}$$

(3)

for any simple future d-homotopy (cf Definition 2) $H: X \times \overrightarrow{T} \to X$ from $H_0 = f$ to $H_1 = g$, and for all $(x, y) \in X^2$. Here $H(x)$ is the d-path arising by restricting $H$ to $x$.

Remark 1
1. Imposing (2) means that every endo-d-map $f \in \overrightarrow{C}(X, X)$ defines a functor from $E \overrightarrow{\pi_1}(X)$ into itself. Altogether they define a monoid action of the monoid $\overrightarrow{C}(X, X)$ on $E \overrightarrow{\pi_1}(X)$ by such endo-functors.
2. Diagram (2) encodes a coherent $lr$-extension property (compare Fajstrup et al. 2004; Goubault and Haucourt 2007) of the morphisms in the subcategory of endo-d-maps with respect to the subcategory of morphisms in the subcategory of extensions.
3. As a consequence of (2), every morphism in $dE \overrightarrow{\pi_1}(X)$ is a composition of just one endo-d-morphism and one extension morphism $(\sigma_*, \tau) \circ f: (x, y) \to (fx, fy) \to (x', y')$.
4. If there is a simple d-homotopy $H$ from $H_0 = f$ to $H_1 = g$ such that $f(x) = H_0(x) = H_1(x) = f(x)$ and $f(y) = H_0(y) = H_1(y) = g(y)$ and
g(y), \ t \in I, \text{ then, according to (3), } f, g \in \overrightarrow{C}(X, X) \text{ give rise to the same morphism } f = g : (x, y) \to (fx, fy) = (gx, gy) \text{ in } dE \overrightarrow{C}_1(X).

5. The functors from the previous paragraphs can be aggregated to define a functor $dE \overrightarrow{C}_1(X)_+ : dE \overrightarrow{C}_1(X) \to \text{Ho Top}$ (and this is why it makes sense to impose the commutativity of (2) and (3) above).

6. Note that, even if the d-space $X$ does not allow any non-trivial loops, the d-extension category may include non-identity endomorphisms arising from combinations of d-maps and of extensions.

7. Inclusion of morphism sets defines functors from $E \overrightarrow{C}_1(X)$, resp. from $d(X)$ into $dE \overrightarrow{C}_1(X)$—all categories have the same objects given by $X^2$. By Calk et al. (2020) above, the latter functor is not faithful in general.

### 2.2 Homotopy flows and inessential d-maps

#### 2.2.1 Homotopy flows

We start by recalling elementary definitions about homotopy notions in directed algebraic topology: We distinguish the directed unit interval $\overrightarrow{I}$ with $\overrightarrow{P}(\overrightarrow{I})$ consisting of all non-decreasing self maps (d-paths) and the undirected unit interval with $\overrightarrow{P}(I)$ consisting of all constant maps (paths).

**Definition 2** Let $X$ and $Y$ denote two d-spaces.

1. A d-map $H : X \times \overrightarrow{I} \to Y$ is called a simple d-homotopy from $f = H_0$ to $g = H_1$ (also: a future d-homotopy from $f$ to $g$, or a past d-homotopy from $g$ to $f$)
2. A d-map $H : X \times I \to Y$ is called a dihomotopy (or neutral d-homotopy).
3. Simple d-homotopies $H$ from $X$ to $X$ with $H_0 = \text{id}_X$ (resp. $H_1 = \text{id}_X$) are called future (resp. past) homotopy flows. Simple dihomotopies with $H_0 = \text{id}_X$ (resp. $H_1 = \text{id}_X$) are called neutral homotopy flows.

Both for a d-homotopy and for a dihomotopy, all level maps $H_t : X \to Y$, $0 \leq t \leq 1$, are d-maps. Only for d-homotopies, every path $H(x, -) : I \to Y, \ x \in X$, is a d-path in $Y$.

The notion of homotopy flow (Raussen 2007) is meant to capture some, but not all, of the properties of a flow for a dynamical system associated to a vector field. Note that it is not demanded that the level maps $H_t : X \to X, \ 0 \leq t \leq 1$, are invertible; they need neither be injective nor surjective. The map $H$ is not supposed to satisfy a group (or monoid) law either.

**Concatenations and compositions** Two simple d-homotopies between endo-d-maps on a d-space $X$, say from $h$ to $f$, resp. from $f$ to $g$, can be concatenated to yield a d-homotopy from $h$ to $g$. In particular, a homotopy flow $H$ from $id_X$ to $f$ can be concatenated with a simple d-homotopy from $f$ to $g$ on $X$ to yield a homotopy flow from $id_X$ to $g$.

Homotopy flows on a given d-space $X$ can be composed in various ways (cf Raussen 2007). Here we propose a generalized construction: For two simple future d-homotopies $G, H : X \times \overrightarrow{I} \to X$ let $[G, H] : X \times \overrightarrow{I}^2 \to X$
be given by $[G, H](s, t; x) = G_s(H_t(x))$. In particular, $[G, H](0, 0) = G_0 \circ H_0$, $[G, H](s, 0) = G_s \circ H_0$, $[G, H](0, t) = G_0 \circ H_t$, $[G, H](s, 1) = G_s \circ H_1$, $[G, H](1, t) = G_1 \circ H_t$ and $[G, H](1, 1) = G_1 \circ H_1$. Remark that this construction does not commute: in general, $[G, H] \neq [H, G]$.

Any d-path $p \in \overrightarrow{P} (\overrightarrow{T}^{2})_{(0,0)}^{(1,1)}$ provides a simple d-homotopy $[G, H] \circ p$ from $G_0 \circ H_0$ to $G_1 \circ H_1$. In particular, d-paths on the 1-skeleton of $\overrightarrow{T}^{2}$ joining $(0, 0)$ and $(1, 1)$ yield such simple d-homotopies “via” $G_1 \circ H_0$, resp. “via” $G_0 \circ H_1$. In the special case of homotopy flows $G, H$, their composition $[G, H]$ provides homotopy flows ending at $G_1 \circ H_1$ (via $G_1$, resp. via $H_1$).

Similarly for past d-homotopies on $X$. For neutral homotopy flows the path $p$ does not have to be directed. The construction above can be generalized to yield a composition $[H_1, \ldots, H_n] : X \times \overrightarrow{T}^n \rightarrow X$ of $n$ simple d-homotopies $H_i$.

### 2.2.2 Psp homotopy flows and inessential d-maps

Ziemiański (Ziemiański 2019, Definition 2.6) gives a list of very natural requirements to a family $\mathcal{F}$ of morphisms in the category $\textbf{Top}$ to be considered as an equivalence system. We will concentrate here on the following particular cases (also considered in Ziemiański (2019)):

- $\mathcal{F} = \mathcal{F}_\infty$ consists of all (weak) homotopy equivalences.
- $\mathcal{F} = \mathcal{F}_0$ consists of all maps inducing bijections on sets of path components ($\pi_0$).
- $\mathcal{F} = \mathcal{H}_{A,k}$ consists of all maps inducing isomorphisms on $H_n(-; A)$ for $n \leq k$; $A$ denotes an abelian group.

In the following, all families $\mathcal{F}$ are supposed to be sandwiched between $\mathcal{F}_0$ and $\mathcal{F}_\infty : \mathcal{F}_0 \subseteq \mathcal{F} \subseteq \mathcal{F}_\infty$. We are, first of all, interested in homotopy flows that preserve path spaces up to an $\mathcal{F}$-equivalence:

**Definition 3** 1. A d-map $f : X \rightarrow Y$ is called $\mathcal{F}$-path space preserving ($\mathcal{F}$-psp for short) if $\overrightarrow{T} (f) : \overrightarrow{T}(X)_{x_1}^{x_2} \rightarrow \overrightarrow{T}(Y)_{f(x_1)}^{f(x_2)}$ is an $\mathcal{F}$-equivalence for all reachable pairs $(x_1, x_2) \in X^2$.
2. A d-homotopy (in particular, a homotopy flow) is called $\mathcal{F}$-psp if every d-map $H_t : X \rightarrow X$, $t \in I$, is psp.
3. An endo d-map $f : X \rightarrow X$ is called future/past/neutral $\mathcal{F}$-inessential if there exists a future/past/neutral $\mathcal{F}$-psp homotopy flow with $H_0 = id_X$ and $H_1 = f$ (resp. $H_0 = f$ and $H_1 = id_X$).

In the following, we will write abbreviate the “flavours” future with $\alpha = +$, past with $\alpha = -$, and neutral with $\alpha = 0$. We may then talk about an $\alpha \mathcal{F}$ homotopy flow, resp. inessential map.

**Lemma 1** Let $X$ denote a d-space.

1. The concatenation of an $\alpha \mathcal{F}$ homotopy flow on $X$ ending at $f$ with an $\alpha \mathcal{F}$ homotopy from $f$ to $g$ (cf Sect. 2.2.1) yields an $\alpha \mathcal{F}$ homotopy flow ending at $g$.  

\[ \mathfrak{S} \text{ Springer} \]
2. The $\alpha\mathcal{F}$-inessential maps on a d-space $X$ are closed under composition; they form a submonoid $\Sigma_{\alpha\mathcal{F}}(X) \subset \overline{C}(X, X)$ of the monoid of all endo-d-maps on $X$.

3. Consider the morphisms denoted $f$ in (2) in the case where $f$ is $\mathcal{F}$-psp. Then the functor $dE\overrightarrow{\pi}_1(X)\ast$ (cf Sect. 2.1.5, Remark 1) sends all these morphisms into $\mathcal{F}$-equivalences.

4. If $f$ is $+\mathcal{F}$-inessential via a $+\mathcal{F}$ homotopy flow $H$ keeping $x_1$ fixed (i.e., $f(x_1) = x_1$), then all extensions $(c_{x_1}, \ast H(x_2)) : (x_1, x_2) \rightarrow (x_1, f(x_2))$ starting at $x_1$ induce $\mathcal{F}$-equivalences. Likewise, if $f$ is $-\mathcal{F}$ inessential via a $-\mathcal{F}$ homotopy flow $H$ from $f$ to $id_X$ fixing $x_2$, then extensions $(H(x_1)\ast, c_{x_2}) : (x_1, x_2) \rightarrow (f(x_1), x_2)$ ending at $x_2$ induce $\mathcal{F}$-equivalences.

**Proof** The statements follow from the construction of compositions of (psp) homotopy flows in Sect. 2.2.1, from Definition 3 and from (3) in the case where one of the maps is the identity.

**Remark 2** 1. In previous work (Fajstrup et al. 2004; Goubault and Haucourt 2007), attention was given to psp-properties of extension morphisms and, moreover, a pushout/pullback property encompassing that the psp property can be “matched“ (on an individual basis) at start and end points. Asking for a psp homotopy flow means that there has to be a global witness (the psp homotopy flow) for these psp properties. As the example in Sect. 1.2 shows, it may be necessary to perturb start and end point coherently together to obtain “constant” path spaces (up to $\mathcal{F}$-equivalence). Hence, we are not going to compress the effects of inessential extension morphisms but those of inessential $d$-maps.

2. The concepts “psp homotopy flow” and “inessential $d$-map” make also sense from a computer science applied perspective. A psp homotopy flow captures coherent perturbations of all executions regardless of end points on a Higher Dimensional Automaton (HDA) in concurrency theory (cf Pratt 1991; van Glabbeek 2006; Fajstrup et al. 2016).

### 2.3 Localization and component categories

#### 2.3.1 Inessential subcategories: definitions

According to Lemma 1, the $\mathcal{F}$-inessential $d$-maps on $X$ (cf Definition 3.3) form submonoids $\Sigma_{+\mathcal{F}}(X)$, $\Sigma_{-\mathcal{F}}(X)$, resp. $\Sigma_{0\mathcal{F}}(X)$ (the neutral ones) of the monoid of all endo-$d$-maps on $X$. As such, they give rise to wide subcategories of $\overrightarrow{dE\pi}_1(X)$ that we call $\Sigma_{\alpha\mathcal{F}}(X), \alpha = +, -, 0$. Objects are always the same sets $\rightarrow X_2$ of reachable points, regardless the decorations $\alpha$ and $\mathcal{F}$.

A fourth flavour $\pm$ comes up as follows: Let $\Sigma_{\pm\mathcal{F}}(X)((x, y), (x', y')) := \{ f \in \Sigma_{\pm\mathcal{F}}(X)((x, y), (x', y')) | \exists g \in \Sigma_{\mathcal{F}}(X)((x', y'), (x, y)) : \overrightarrow{T}(g \circ f) : \overrightarrow{T}(X)^x_{x'} \rightarrow \overrightarrow{T}(X)^y_{y'}$ is $\mathcal{F}$-homotopic to the identity map$\}$; i.e $\overrightarrow{T}(g \circ f)$ induces the identity map on all homotopy groups, on path components, resp. on a range of homology groups.
In the following (starting in Sect. 2.3.4), we will concentrate on (mixed) subcategories $\Sigma_\alpha^E \mathbb{P}_1(X) \subset dE \mathbb{P}_1(X)$, $\alpha = +, -, 0, \pm$, with

Objects: Pairs of points in $X^2$.
Morphisms: arise as finite compositions of inessential morphisms in $\Sigma_\alpha^E(X)$ with extension morphisms in $E \mathbb{P}_1(X)$ obeying to the relations (2) and (3); the latter for $f = id_X$.

As in Sect. 2.1.5, Remark 1, one should think of the monoid $\Sigma_\alpha^E(X)$ as “acting” on the extension category $E \mathbb{P}_1(X)$ by endo-functors, this time leaving moreover the homotopy types of associated trace spaces invariant.

2.3.2 Localization

Given a category $\mathcal{C}$ with subcategory $\Sigma$, the localization (Borceux 1994) of $\mathcal{C}$ with respect to $\Sigma$ consists of a category $\mathcal{C}[\Sigma^{-1}]$ together with a functor $L : \mathcal{C} \to \mathcal{C}[\Sigma^{-1}]$ turning $\Sigma$-morphisms into isomorphisms, and such that a functor $F : \mathcal{C} \to \mathcal{D}$ factors uniquely through $L$ if and only if it sends all $\Sigma$-morphisms into isomorphisms.

In practice, localization consists in adding formal inverses to the $\Sigma$-morphisms; the morphisms in the localized category are finite zig-zags consisting of morphisms in the category $\mathcal{C}$ and inverses of morphisms in the subcategory $\Sigma$. A prominent example defines the category $\text{Ho} \to \text{Top}$ as the result of localizing the subcategory whose morphisms $\Sigma = \mathcal{F}_\infty$ consists of all weak homotopy equivalences.

We will consider categories arising from a d-space $X$. Of particular interest are the localized categories $\Sigma_\alpha^E \mathbb{P}_1(X)[\Sigma_\alpha^E(X)^{-1}]$, $\alpha = +, -, 0, \pm$: all morphisms arising from inessential d-maps (and no extension morphisms) are inverted. In these cases, we can draw several conclusions from (2) and (3) in Sect. 2.1.5:

Lemma 2 1. The relations from (2) and (3) lead to reverse relations concerning morphisms $f^{-1} : (fx, fy) \to (x, y)$ for $f \in \Sigma_\alpha^E(X)$ and $\mathcal{F}$ psp homotopy flows $H$ on $X$:

(a) $(\sigma \ast, \ast \tau) \circ f^{-1} = f^{-1} \circ (f \sigma \ast, \ast f \tau)$.
(b) $H(y) \ast \circ f^{-1} = \ast H(x) : (fx, fy) \to (x, fy)$.

2. Let $g$ denote an inessential d-map on $X$. Then $\mathbb{T}(g)$ induces bijections between morphism sets $E \mathbb{P}_1(X)((x, y), (x', y')) \to E \mathbb{P}_1(X)((gx, gy), (gx', gy'))$.

Proof 1. follows directly from (2) and (3) in Sect. 2.1.5.

2. $E \mathbb{P}_1(X)((x, y), (x', y')) = \pi_0 \mathbb{T}(X)^x \times \pi_0 \mathbb{T}(X)^y \cong \pi_0 \mathbb{T}(X)^{gx} \times \pi_0 \mathbb{T}(X)^{gy} (X)^{gy} = E \mathbb{P}_1(X)((gx, gy), (gx', gy'))$.

By the universal property characterizing localization, for $\mathcal{F} = \mathcal{F}_\infty$, the functors $\mathbb{T}(X)^x$ into $\text{Top}$ and $\mathbb{P}_1(X)^x$ into $\text{Ho} \to \text{Top}$ (cf Sect. 2.1.3) extend to give rise to functors from the localized categories into $\text{Ho} \to \text{Top}$ for which we will use the same notation. Similarly, for a wider class of equivalence systems, for the functors with target category $\text{Ab}$ arising from composing with eg homology or $\text{Set}$ from taking connected components.
2.3.3 Component categories

Going one step further, one may form from a category $\mathcal{C}$ with a subcategory $\Sigma$ a quotient category $\mathcal{C}/\Sigma$ together with a quotient functor $Q: \mathcal{C} \rightarrow \mathcal{C}/\Sigma$ sending morphisms in $\Sigma$ to identities and such that a functor $F: \mathcal{C} \rightarrow \mathcal{D}$ factors uniquely through $Q$ if and only if it sends all $\Sigma$-morphisms to identities (Bednarczyk et al. 1999; Fajstrup et al. 2016). The quotient category has as objects the path components of $\mathcal{C}$-objects with respect to paths arising by composing morphism in $\Sigma$ and $\Sigma^{-1}$. Morphisms in the quotient category are represented by morphisms in the category $\mathcal{C}/\Sigma$, i.e., by concatenations of morphisms in the original category and inverses of $\Sigma$-morphisms. Representatives can be composed if just their target, resp. source are situated in the same component (plug in an arbitrary $\Sigma$-morphism to obtain a morphism representing the composition); cf. e.g. (Bednarczyk et al. 1999; Fajstrup et al. 2016) for details. In particular, every $\Sigma$-morphism in $\mathcal{C}$ represents an identity in the component category $\mathcal{C}/\Sigma$.

By the universal properties, the quotient functor factors over the localization functor giving rise to a functor $\hat{Q}: \mathcal{C}[\Sigma^{-1}] \rightarrow \mathcal{C}/\Sigma$. This functor is not always an equivalence of categories; it is so if $\mathcal{C}$ is loop-free, i.e., if it contains only identities as endomorphisms; cf. (Goubault and Haucourt 2007; Fajstrup et al. 2016).

2.3.4 Pair component categories

Since objects are interpreted as path components, we will use the notation $\mathcal{P}_0(\mathcal{C}; \Sigma) = \mathcal{C}/\Sigma$ for relevant categories of pairs in our context.

In the following, we describe a number of interesting pair component categories; in all of them, pairs $(x, y)$ and $(x', y')$ in $\mathcal{P}^2$ give rise to the same object (then called component) if and only if there exists a zig-zag $(x, y) \rightarrow (x_1, y_1) \leftarrow (x_2, y_2) \rightarrow \cdots \rightarrow (x_n, y_n) = (x', y')$ of $\Sigma$-morphisms. For $\Sigma = \Sigma_\mathcal{F}^\alpha$, $\alpha = +, -, 0, \pm$, those are induced by zig-zags of psp homotopies flows joining them. We will call the components in these categories future, past, neutral resp. total components.

By far the most important pair component categories arise as categories of components $\mathcal{C}/\Sigma$ with $\mathcal{C} = \Sigma_\mathcal{F}^\alpha E \mathcal{P}_1(X)$ and $\Sigma = \Sigma_\mathcal{F}^\alpha (X)$. As discussed above, objects (components) correspond to path components among reachable pairs along psp homotopy flows. Extension morphisms are identified if equivalent up to an inessential endo-d-map. The key relations go back to (2) and (3)—for $f = id_X$—in Sect. 2.1.5.

For an inessential endo-d-map $f$ on $X$ and d-homotopy classes $\sigma, \tau$, the morphisms $(\sigma_\ast, \ast\tau): (x, y) \rightarrow (x', y')$ and $((f \circ \sigma)_\ast, \ast(f \circ \tau)): (fx, fy) \rightarrow (fx', fy')$ represent the same morphism in the component category. Likewise, cf. Lemma 2.2, morphisms $(\sigma_\ast_\ast, \ast\tau_\ast): (fx, fy) \rightarrow (fx', fy')$ arise from morphisms $(\sigma_\ast, \ast\tau): (x, y) \rightarrow (x', y')$ under $f$.

In the remaining part of the paper, we will use the shorter notation $\mathcal{P}_0(X; \alpha, \mathcal{F})_\ast = \mathcal{P}_0(\Sigma_\mathcal{F}^\alpha E \mathcal{P}_1(X); \Sigma_\mathcal{F}^\alpha (X))$, $\alpha = +, -, 0, \pm$, for the future, past, neutral resp. total pair component categories. Inclusion induces functors.
\[
\pi_0(X; \pm, \mathcal{F})^* \to \pi_0(X; +, \mathcal{F})^*.
\]
\[
\pi_0(X; -, \mathcal{F})^* \to \pi_0(X; 0, \mathcal{F})^*.
\]

These are onto on objects and, since every morphism arises from an extension, full on morphisms.

For \( \mathcal{C} = \text{Top} \) and \( \Sigma \) consisting of isomorphisms, the quotient category \( \mathcal{C}/\Sigma \) is the naive category of homotopy types. By the universal property characterizing quotient categories, the functors \( \to \pi_0(X; \alpha, \mathcal{F})^* \) factors to give rise to functors to this category of homotopy types. Likewise for \( \mathcal{F}_0 \), \( \mathcal{C} = \text{Sets} \) and \( \Sigma \) consisting of bijections; or \( \mathcal{H}_{A; k}, \mathcal{C} = A - \text{mod} \) and \( \Sigma \) consisting of isomorphisms.

**Remark 3** There are several variations on this theme that we are not going to follow up:

1. The full category \( \mathcal{C} = dE \pi_1(X) \) with the same subcategories \( \Sigma = \Sigma^e_{\mathcal{F}}(X) \); resulting in a pair component with the same objects as above but with an additional “action” of essential endo-d-maps (the quotient of morphisms in \( dE(X) \) with respect to \( \Sigma^e_{\mathcal{F}}(X) \) and its inverses; see Dubut 2017 below).
2. In both cases: Pair component categories with departure the extension category \( E \to T(X) \) of the trace category instead of that of the fundamental category.
3. Forgetting extensions, and considering \( \mathcal{C} = d(X), \Sigma = \Sigma^e_{\mathcal{F}}(X) \), morphisms given by an endo d-map \( f \) and its compositions \( g \circ f \) and \( f \circ g \) with an inessential such map \( g \) are identified in the quotient category.

### 3 Properties of homotopy flows and components

#### 3.1 Components are path-connected

Any homotopy flow on a d-space \( X \) yields, when restricted to a point or a pair of points, a path connecting the ends. This elementary observation implies:

**Lemma 3** Any component \( C \subset \to X^2 \) is path-connected. For \( \alpha = +, -, \pm \), two elements of the same component can be connected by a zig-zag of (pairs of) d-paths.

#### 3.2 Future components are future connected

The following definition adapts similar ones from (Fajstrup et al. 2004; Ziemiański 2019) to the pair setting:

**Definition 4** A subset \( C \subset \to X^2 \subset X \times X \) is called future connected if, for any two pairs \((x_1, y_1), (x_2, y_2) \in C \), there exist \((x, y) \in C \) and d-paths \( \alpha_i, \beta_i \in \to P(X), i = 1, 2 \), such that \((\alpha_i(t), \beta_i(t)) \in C \) for all \( t \), \( \alpha_i(0) = x_i, \beta_i(0) = y_i, \alpha_i(1) = x, \beta_i(1) = y \).

Past connectivity is defined similarly. We omit the decoration \( \mathcal{F} \).
Proposition 1  Future components are future connected. Past components are past connected. Total components are both.

Proof  We give a proof of future connectivity; the other cases follow by considering the reverse directed space. There are essentially two zig/zag situations to consider (arrows indicate $+\mathcal{F}$-psp homotopy flows $G, H : X \times \overrightarrow{T} \to X$ by their restrictions to pairs of points):

In the case on the left, the d-paths joining $(x_i, y_i)$ with $(x, y)$ within $C$ can be chosen as restrictions of $G$ and $H$ to $(x_i, y_i)$.

In the case on the right, there is a psp homotopy flow $G : X \times \overrightarrow{T} \to X$ with $G_1(x_1) = x_1, G_1(y_1) = y_1$ and a psp d-homotopy flow $H : X \times \overrightarrow{T} \to X$ with $H_1(x_2) = x_2, H_2(y_2) = y_2$. In the notation from Sect. 2.2.1, let $x := [G, H][(1, 1); (x, y)] = G_1(H_1(x))$ and $y := [G, H][(1, 1); (x, y)] = G_1(H_1(y))$. The dipaths $(\alpha_1(t), \beta_1(t)) = [G, H][(1, 1); (x, y)]$ connect $(x_1, y_1)$ with $(x, y)$ within $C$. The dipaths $(\alpha_2(t), \beta_2(t)) = [G, H][(1, 1); (x, y)]$ connect $(x_2, y_2)$ with $(x, y)$ within $C$.

The general zig-zag situation follows by an inductive argument. □

3.3 Regions fixed by (psp) homotopy flows

3.3.1 Pre-cubical sets. Cubical complexes

Definition 5  1. A pre-cubical set $X$ (also called a $\Box$-Set) is a sequence of disjoint sets $X_n, n > 0$, equipped with face maps $d_i^\alpha : X_n \to X_{n-1}, \alpha \in \{+, -\}, 1 \leq i \leq n$, satisfying the pre-cubical relations: $d_i^\alpha d_j^\beta = d_{j-1}^\beta d_i^\alpha$ for $i < j$.

Elements of $K_n$ are called $n$-cubes, those of $K_0$ are called vertices.

2. The geometric realization of a pre-cubical set $X$ is the d-space

$$|X| = \bigcup_{n \geq 0} X_n \times \overrightarrow{T}^n / [d_i^\alpha(c), x] ~ [c, \delta_i^\alpha(x)]$$

with $\delta_i^\alpha(x_1, \ldots, x_{n-1}) = (x_1, \ldots, x_{i-1}, s_\alpha, x_i, \ldots, x_{n-1})$ and $s_\alpha = 0$ (resp. 1) for $\alpha = -$ (resp. $\alpha = +$).

3. A path $p \in \overrightarrow{P}(|X|)$ is directed if there are $0 = t_0 < t_1 < \cdots < t_k = 1$, cubes $c_i \in X_{n_i}$ and directed paths $p_i : [t_{i-1}, t_i] \to \overrightarrow{T}^{n_i}$ with $p(t) = [c_i, p_i(t)]$ for $t \in [t_{i-1}, t_i]$.

Pre-cubical sets are the underlying structure of a Higher-Dimensional Automaton (Pratt 1991; van Glabbeek 1991, 2006; Fajstrup et al. 2016); those have moreover a
coherent labelling of the 1-cubes. In this section, we consider homotopy flows on the geometric realization $|X|$ of a pre-cubical set $X$, also called a cubical complex. We will often just write $X$ for $|X|$.

3.3.2 Homotopy flows and components

Let $Y \subset X$ denote a subset of a d-space $X$. Its past $\downarrow Y := \{ x \in X | \exists y \in Y : \overrightarrow{P}(X)^y_x \neq \emptyset \}$ consists of all elements in $X$ that can reach an element in $Y$. Its future $\uparrow Y := \{ x \in X | \exists y \in |c| : \overrightarrow{P}(X)^y_x \neq \emptyset \}$ consists of all elements in $X$ that can be reached from an element in $Y$. Both contain $Y$.

A cube $c$ in a finite dimensional cubical complex $X$ is called a future branch cube, resp. a past branch cube (Raussen 2012) if there exist more than one maximal cube containing it as a bottom boundary cube (iterated $d^-$), resp. top boundary cube (iterated $d^+$).

**Proposition 2**

1. For every (neutral) homotopy flow on $X$ and every future branch cube $c$ there exists $T > 0$ such that $H(|c| \times [0, T]) \subseteq \downarrow |c|$.

2. For every (neutral) homotopy flow on $X$ and every past branch cube $c$ there exists $T > 0$ such that $H(|c| \times [0, T]) \subseteq \uparrow |c|$.

3. A future (resp. past) homotopy flow on $|X|$ preserves future (resp. past) branch cubes.

**Proof**

1. Let $C = \bigcup |d|$, the union of all cubes $d$ that have $c$ as a lower face. For every homotopy flow on $X$, since $|c|$ is compact, there exists $T > 0$ such that $H(|c| \times [0, T]) \subseteq \downarrow C$. Assume there exists $x = [c; (t_1, \ldots, t_k)] \in |c|$ and $0 < t \leq T$ such that $H_t(x) \in |d| \setminus |c|$ for $0 < t \leq T$ for a cube $d$ containing $c$ as a lower face. Let $e$ denote a maximal cube containing $c$ but not $d$ as a lower face. Let $y = [e, (t_1, \ldots, t_k, \varepsilon_1, \ldots, \varepsilon_{n-k})]$ be contained in $|e| \setminus |d|$, $\varepsilon_i > 0$; we assume without restriction that $c$ occupies the first $k$ coordinates. Observe that there exists a d-path $\sigma$ from $x$ to $y$. The d-path $H_t(\sigma)$ starts in $H_t(x) \in |d| \setminus |c|$ and ends in $H_t(y)$ which is contained in $|e| \setminus |d|$ for small $t$. Contradiction!

2. The same reasoning applied to the reverse d-structur on $X$ (d-paths replaced by reverse d-paths) yields the result for past branch cubes.

3. is an immediate consequence of 1. and 2. \hfill $\Box$

The following result is straightforward; it turns out to be very useful in Sect. 4:

**Lemma 4** Let $Y \subseteq X$ denote a subspace of a d-space $X$.

1. A d-map $f : X \to X$ (resp. a dihomotopy $H : X \times I \to X$) that keeps $Y$ invariant ($f(Y) \subseteq Y$, resp. $H(Y \times I) \subseteq Y$), keeps also invariant its closure $\overline{Y}$, its past $\downarrow Y$ and its future $\uparrow Y$.

2. A future (resp. past) homotopy flow $H : X \times \overrightarrow{I} \to X$ keeping $Y$ invariant keeps also invariant the complement $X \setminus \downarrow Y$ of its past (resp. the complement $(X \setminus \uparrow Y)$ of its future.

3. Intersections of invariant sets are invariant.
Corollary 1  1. Any future (resp. past) homotopy flow $H : X \times \hat{T} \to X$ fixes a future (resp. past) branch point (=0-cell) $b \in X_0$.
2. Any future homotopy flow preserves the past $\downarrow b = \{ x \in X | \hat{P}(X)_x^b \neq \emptyset \}$ of a future branch point $b$ and its complement $X \setminus \downarrow b$.
3. Any past homotopy flow preserves the future $\uparrow b = \{ x \in X | \hat{P}(X)_x^b \neq \emptyset \}$ of a past branch point $b$ and its complement $X \setminus \uparrow b$.
4. For any disjoint collections $B_1, B_2$ of future branch points, any future homotopy flow preserves subsets of the form $\bigcap_{b_i \in B_1} \downarrow b_i \cap \bigcap_{b_j \in B_2} (X \setminus \downarrow b_j)$.
5. Similarly for past homotopy flows and collections of past branch points.

For $x \in X$, divide the set $B(X) \subseteq X$ of all future branch points into the set $B_1(x)$ containing all those in $\uparrow x$ and into $B_2(x)$ containing the remaining ones. Let

$$E^+(x) := \bigcap_{b_i \in B_1(x)} b_i \cap \bigcap_{b_j \in B_2(x)} (X \setminus \downarrow b_j).$$

(4)

Obviously, $x \in E^+(x)$. Intersections over empty sets $B_i(x)$ are interpreted as the entire space $X$; in particular, $E^+(x) = X$ if $B_1(x) = B_2(x) = \emptyset$. Observe that the relation defined by $x \simeq y \iff E^+(x) = E^+(y)$ is an equivalence relation on $X$. If $B_1(x) \neq \emptyset$, then $E^+(x)$ is obviously path-connected.

As an immediate consequence of Corollary 1(4–5), we obtain:

Corollary 2  Let $C \subseteq X^2$ denote a future component, ie an object in $\pi_0(X; +, \mathcal{P})^*$. Let $p_i : X^2 \to X$, $i = 1, 2$, denote one of the two projections, and let $x \in X$.
If $x \in p_i(C)$, then $p_i(C) \subset E^+(x)$.

Similar statements apply to past components whose projections are contained in similarly defined sets $E^-(x)$ and to total components whose projections are contained in sets $E^+(x) \cap E^-(x)$.

Remark that for the result in Corollary 2 we did not need a psp-property (preservation of path spaces).

3.3.3 Psp homotopy flows and components

The following property is an immediate consequence of the definitions (for a general $d$-space $X$):

Lemma 5  If two pairs $(x_1, y_1)$ and $(x_2, y_2)$ belong to the same pair component in $\pi_0(X; \alpha, \mathcal{P})^*$, then

1. $\hat{T}(X)_x^{y_1}$ and $\hat{T}(X)_x^{y_2}$ are $\mathcal{P}$-equivalent (ie (weakly) homotopy equivalent, homology equivalent . . . ).
2. Furthermore, there exist paths $p$ and $q$ in $X$ connecting $x_1$ with $x_2$ resp. $y_1$ with $y_2$ such that $\hat{P}(X)_p^{q(t)}$ are all $\mathcal{P}$-equivalent. For $\alpha = +, -, \pm$, these paths can be chosen as zig-zags of $d$-paths.
The following easy observation is useful for many examples and replaces lr-
conditions on left/right extensions (Fajstrup et al. 2004; Goubault and Haucourt 2007),
also called Ore conditions in Dubut (2017):

**Lemma 6** Let $H$ denote a future $\mathcal{F}$-psp homotopy flow, $x_1 \in X, x_2 := H_1(x_1)$. For
every $y_1 \in X$ with $\overrightarrow{T}(X)_{x_1}^{y_1} \neq \emptyset$ there exists $y_2 \in X$ with $\overrightarrow{T}(X)_{x_2}^{y_2} \neq \emptyset \neq \overrightarrow{T}(X)_{y_1}^{y_2}$
such that $(x_1, y_1)$ and $(x_2, y_2)$ are contained in the same $+\mathcal{F}$-component.
Similarly for past $\mathcal{F}$-psp homotopy flows.

**Proof** The $\mathcal{F}$-psp property of $H$ makes sure that $\overrightarrow{T}(H_t) : \overrightarrow{T}(X)_{x_1}^{y_1} \to \overrightarrow{T}(X)_{H_t(x_1)}^{y_1}, t \in I$, and in particular, $\overrightarrow{T}(H_1) : \overrightarrow{T}(X)_{x_1}^{y_1} \to \overrightarrow{T}(X)_{x_2}^{y_2}$ is an $\mathcal{F}$-equivalence. □

### 3.4 Products

Let $X_1, X_2$ denote d-spaces; we will consider our constructs for their product, the d-
space $X = X_1 \times X_2$. There are natural homeomorphisms $\overrightarrow{T}(X) \cong \overrightarrow{T}(X_1) \times \overrightarrow{T}(X_2)$
fibered over $X \cong X_1 \times X_2$, giving rise to natural homeomorphisms $\overrightarrow{T}(X)^{y_1,y_2}_{(x_1,x_2)} \cong \overrightarrow{T}(X_1)^{y_1}_{x_1} \times \overrightarrow{T}(X_2)^{y_2}_{x_2}$ on all fibers, $(x_1, x_2), (y_1, y_2) \in X$. Hence the extension cate-
gory $E \overrightarrow{T}(X)$ is naturally isomorphic to $E \overrightarrow{T}(X_1) \times E \overrightarrow{T}(X_2)$; likewise $E \overrightarrow{\mathcal{F}}_1(X)$ to
$E \overrightarrow{\mathcal{F}}_1(X_1) \times E \overrightarrow{\mathcal{F}}_1(X_2)$.

A pair of endo-d-maps, $f_1$ on $X_1$ and $f_2$ on $X_2$, defines the endo-d-map $f_1 \times f_2$
on $X$. If the maps $f_i$ are $\mathcal{F}$-psp, then so is $f_1 \times f_2$. But not every (psp) d-map on
$X$ is a product. In general, the inclusion of product maps induces monomorphisms
$d(X_1) \times d(X_2) \hookrightarrow d(X)$ and likewise $\Sigma^a_\mathcal{F}(X_1) \times \Sigma^a_\mathcal{F}(X_2) \hookrightarrow \Sigma^a_\mathcal{F}(X)$. After
localization and quotient formation, one obtains from the isomorphism of categories
above:

**Proposition 3** The quotient functor

$$\overrightarrow{\mathcal{F}}_0(X_1; \alpha, \mathcal{F})^* \times \overrightarrow{\mathcal{F}}_0(X_2; \alpha, \mathcal{F})^* \to \overrightarrow{\mathcal{F}}_0(X; \alpha, \mathcal{F})^*$$

is onto on objects and full on morphisms.

### 4 Examples

In this section, we walk through a number of simple, but key examples for which it is
possible to determine pair component categories by elementary considerations.

#### 4.1 Intervals and hyperrectangles

##### 4.1.1 An interval

Let $J \subseteq \mathbb{R}$ denote an interval; it may be (half-)open or closed, bounded or unbounded.
All trace spaces $\overrightarrow{T}(J)^x_\alpha$, $(x, y) \in \overrightarrow{T}^2$, are contractible, and hence any endo-d-map

\[ \boxtimes \] Springer
on \( J \) is automatically psp. Moreover, any two endo-d-maps \( f, g : J \rightarrow J \) are psp-d-homotopic to \( \max(f, g) \) and to \( \min(f, g) \) – by convex combination. In particular, they are all inessential with respect to every choice of \( \alpha \) and \( \mathcal{F} \). In fact, the space of endo-d-maps on \( J \) is contractible.

For every two pairs \((x_1, y_1), (x_2, y_2) \in \overrightarrow{J}^2 \) with \( x_1 \neq y_1 \) there exists an endo-d-map \( f : J \rightarrow J \) with \( f(x_1) = x_2, f(y_1) = y_2 \), for example a piecewise linear map with \( f(t) = x_2, t \leq x_1, \) and \( f(t) = y_2, t \geq y_1 \). Hence, any two pairs \((x_1, x_2), (x_2, y_2) \) are contained in the same (unique) component, and the pair component category \( \overrightarrow{\pi}_0(J; \alpha, \mathcal{F}) \) is the trivial category with one object and one (identity) morphism – for every choice of \( \alpha \) and \( \mathcal{F} \).

### 4.1.2 Hyperrectangles and generalizations

A hyperrectangle is a finite product \( H = J_1 \times \cdots \times J_n \) of intervals. It follows from Proposition 3 that also the pair component category \( \overrightarrow{\pi}_0(H; \alpha, \mathcal{F}) \) is the trivial category with one object and one (identity) morphism.

Using the same reasoning as in Sect. 4.1.1, one can show that pair component categories are trivial, more generally, for subspaces \( K \subseteq \mathbb{R}^n \) satisfying the following property: For every pair \( x, y \in K \), the lines connecting \( x \) and \( y \) with \( \max(x, y) \), resp. with \( \min(x, y) \) are contained in \( K \).

### 4.2 Directed graphs

#### 4.2.1 A branching

A future branching graph is the pre-cubical set consisting of two 1-cubes \( a \) and \( b \) and three 0-cubes \( d_1^-(a) = d_1^-(b), d_1^+(a) \) and \( d_1^+(b) \). Its geometric realization is homeomorphic to the subspace \( B = \{((x, y) \in [0, 1]^2 ] xy = 0 \} \subset \mathbb{R}^2 \) with induced directed topology. All non-trivial path spaces are contractible. Any future homotopy flow \( H : B \times \overrightarrow{I} \rightarrow B \) has to fix the only future branch point, ie the origin \( O = (0, 0) \) (equal to its own past \( \downarrow O \)) as well as the path components of its complement (cf Corollary 1.4 and Lemma 3) \( B_x = \{(x, 0) \mid x \in ]0, 1]\} \) and \( B_y = \{(0, y) \mid y \in ]0, 1]\}; note that \( H \) is automatically psp. It is elementary to see that the future pair category \( \overrightarrow{\pi}_0(B; +, \mathcal{F})^* \) (suppressing identities, and regardless of \( \mathcal{F} \)) is of the form

\[
\begin{align*}
(O, B_x) & \xrightarrow{+} (B_x, B_x) \\
(O, O) & \xrightarrow{+} (B_x, B_x) \\
(O, B_y) & \xrightarrow{-} (B_y, B_y)
\end{align*}
\]

Each arrow represents a well-defined morphism (+ represented by an extension in the future, – by an extension in the past). This category is isomorphic to the exten-
sion category of the (poset) category with three objects $O, B_x, B_y$ and non-reversible relations given by $O < B_x$ and $O < B_y$.

For the past pair component category, note that every reachable pair of points can be connected with the pair $(O, O)$ by a past psp homotopy flow. Hence the past pair category $\mathcal{F}_0(B; -, \mathcal{F})^*$ is the trivial category with one object and one identity morphism.

The total pair category $\mathcal{F}_0(B; \pm, \mathcal{F})^*$ coincides with the future past category, the neutral pair category $\mathcal{F}_0(B; 0, \mathcal{F})^*$ is also trivial.

4.2.2 Particular directed graphs

We will consider a directed graph $G$ (a one-dimensional pre-cubical set), with the property that there is at most one directed path between two vertices. Morphisms are thus either empty or singletons, and this gives rise to a partial order $\leq$ on the vertices. Restrict this partial order to the (future) branch points (out-degree $> 1$). For every branch point $b_i$, consider the subgraph $G_i := \downarrow b_i \cup b_j < b_i \downarrow b_j$; moreover the path-components $G^{\text{top}}_k$ of $G^{\text{top}} := G \cup_j \downarrow b_j$; the latter correspond to top branches not including any branch point.

**Lemma 7** The future components (objects of the future pair component category $\mathcal{F}_0(G; +, \mathcal{F})^*$) are products of subgraphs of the form

- $G_i \times G_1$ for $b_i \leq b_i$
- $G_i \times G^{\text{top}}_k$ if $G^{\text{top}}_k$ is reachable from $b_i$, or
- $G^{\text{top}}_k \times G^{\text{top}}_k$.

Morphisms are inherited from the partial order on the branch points.

**Proof** It follows from Corollary 2 that a component must be contained in one of the products of subgraphs described above. On the other hand, any pair of points $(x_i, x_j) \in G_i \times G_1$ can be connected by a future homotopy flow (which is automatically psp) with $(b_i, b_i)$ fixing the complement of $G_i \cup G_1$. Likewise any pair of points $(x_i, x_k) \in G_i \times G^{\text{top}}_k$ can be connected by a zig-zag of future homotopy flows with any other pair in $G_i \times G^{\text{top}}_k$. \[\square\]

A similar result identifies past pair components (objects in $\mathcal{F}_0(G; -, \mathcal{F})^*$) with products of subgraphs between past branch points or of bottom branches. For total pair components (objects in $\mathcal{F}_0(G; \pm, \mathcal{F})^*$), both future and past branch points, top branches and bottom branches have to be taken into account. For the neutral pair components (objects in $\mathcal{F}_0(G; 0, \mathcal{F})^*$), Proposition 2 tells us: Factors of components arise as subgraphs arising as zig-zags of d-paths between branch-points and connecting a past branch point with a future branch point (no intermediate future branch point) or connecting a future branch point with a past branch point (no intermediate past branch point) by a reverse d-path. Top branches and bottom branches are identified with a branch point and do not give rise to components.

**Example 1** The directed graph representing the letter $M$ has one future branch vertex and two past ones. $M^{\text{top}}$ has two path components, and $\mathcal{F}_0(M; +, \mathcal{F})^*$ has five pair
Pair component categories for directed spaces

components. $M^{bot}$ has three path components; taking reachable pairs among the two branch vertices and these components leads to nine components in $\bar{\pi}_0(M; -, \mathcal{F})_*$. For the total pair component category, $\bar{\pi}_0(M; \pm, \mathcal{F})_*$, the three branch points and the four components of the complement stay invariant; this results in 15 pair components. The neutral pair component category $\bar{\pi}_0(M; 0, \mathcal{F})_*$ is trivial.

It is more complicated to determine components for graphs with several directed paths between certain pairs of vertices (thus including non-directed loops). For a simple example, consult Sect. 4.3.1 below.

4.3 Simple cubical complexes without directed loops

4.3.1 Boundary of a square

We consider the boundary $\partial \Box^2$ of the 2-cube $\Box^2$. Its geometric realization $X = \partial[0, 1]^2$ decomposes into $A = \{(0, 0)\}$, $C = \{(1, 1)\}$, $B_1 = \{(x, 0)| x > 0\} \cup \{(1, y)| y < 1\}$ and $B_2 = \{(0, y)| y > 0\} \cup \{(x, 1)| x < 1\}$; we wish to show that its component category $\pi_0(X; \alpha, \mathcal{F})_*$ is given by

\[
\begin{array}{ccc}
A & B_1 & B_1 C \\
+ & + & + \\
\downarrow & \downarrow & \downarrow \\
A B_1 & B_1 C & + \\
\uparrow & \uparrow & \uparrow \\
A B_2 & + & - \\
\downarrow & \downarrow & \downarrow \\
A C & C C & - \\
\uparrow & \uparrow & \uparrow \\
B_2 B_2 & - & + \\
\end{array}
\]

The path space $\bar{P}(\partial \Box^2)_A^C$ consists of two contractible components; all other non-empty path spaces are contractible. In particular, every psp-homotopy flow preserves both $A$ and $C$ and their complement $B_1 \cup B_2$. The sets $B_1$ and $B_2$ are not connected to each other. By Lemma 3.2, no component can contain sources, resp. targets from more than one $B_i$—since projections of connected spaces are connected.

As a consequence, there are three one element components $(A, C)$, $(A, A)$ and $(C, C)$. All other components are contained in $(A, B_i)$, $(B_i, C)$, $(B_i, B_i)$, $i = 1, 2$. It is easy to find a (one-zig one-zag) psp homotopy flow connecting pairs within the given regions; for a formal justification, cf Sect. 5.

Morphisms that can be represented by future (resp. past) extensions are marked with $+$ (resp. $-$). A mark is in red if the extension (with target $AC$) does not cover a homotopy equivalence of path spaces. The left square marked with $+$ and the right square marked with $-$ do not commute; the mixed top and bottom squares do. Not surprisingly, this category is (isomorphic to) the extension category of the graph category on a directed graph with vertices $A$, $B_1$, $B_2$, $C$ and directed arrows from $A$ to $B_i$ and from $B_i$ to $C$. 

\[\text{Springer}\]
For \( X = \partial \square^2 \), the past pair component category and also the total pair component category are isomorphic to the future pair component category: \( X \) is \( d \)-homeomorphic to the space with the reverse \( d \)-path structure. Finally, also the neutral pair category yields the same result: A neutral psp-homotopy flow has to preserve the pair \((A, C)\) and hence \( A \) and \( C \); the rest of the argument is as above.

The \( d \)-space \( Y = I^2 \setminus J^2 \) with \( J = ]j_0, j_1[ \subset I = [0, 1] \) directed intervals (i.e., a square from which a minor square has been deleted, arising as model of a very simple HDA modeling mutual exclusion) yields the same results for the pair component categories. For the neutral category \((\alpha = 0)\), one may use the following argument by comparison: Consider a piecewise linear \( d \)-map \( f : I \to I \) with \( f(0) = f(j_0) = j_0, f(t) = t, j_0 \leq t \leq j_1, f(j_1) = f(1) = j_1 \). Then \( f^2 \) is a psp map from \( Y \) into \( X' := \partial[j_0, j_1]^2 \) leaving \( X' \) pointwise fix, and \( X' \) is \( d \)-homeomorphic to \( X \). Convex combination of \( id_Y \) and \( f^2 \) defines a neutral psp \( d \)-homotopy between these two maps, fixing \( X' \) pointwise, and thus exhibits \( X' \) as a directed deformation retract of \( Y \) with isomorphic neutral pair component category.

The deformation retraction above is not given by a future nor by a past \( d \)-homotopy. But it is not difficult to check that the pair component categories \( \pi_0(Y; \alpha, \mathcal{F})^* \) are all mutually isomorphic.

### 4.3.2 Swiss flag

The “Swiss flag” is an HDA that arises as a model for two processes only interacting via capacity one semaphores (Fajstrup et al. 2006, 2016). It can be described by a Euclidean cubical complex (cf Sect. 5.4), a pre-cubical set whose geometric realization can be embedded into a “cubical plane”, including a deadlock \( D \) – only constant paths with that source, a “doomed region” \( d \) - every \( d \)-path starting in \( d \) cannot leave \( \downarrow D \) – and an unreachable region \( u \). It has a directed deformation retract (Dubut 2017) given by the directed graph

![Diagram](image)

with two additional 2-cubes \( d \) and \( u \) glued in – with vertices at \( A, X_1, X_2, D, \) resp. \( U, Y_1, Y_2, C \). The geometric realization of this 2-complex will be called \( S \).

\( X_1 \) and \( X_2 \) represent the only future branch points in \( S \). The intersection \( \downarrow X_1 \cap \downarrow X_2 \) of their pasts is given by the vertex \( A \). The intersection \( \downarrow X_i \cap (S \setminus \downarrow X_j) \) of the past of
one of them with the complement of the other’s are the half-open 1-cells $x_i$ (including $X_i$, excluding $A$). The intersection $(S \setminus X_1) \cap (S \setminus X_2)$ of their complements has two connected components: one of them is the complement of the entire 2-cell $d$; the other consists of $d$ apart from the entire two lower 1-cells $x_i$ (corresponding to the doomed region). All of these subspaces are preserved by any future d-homotopy flow by Corollary 1.

The pair $(A, C)$ is the only one representing a non-trivial path space. Hence, as in 4.3.1, none of the other areas can be moved into $C$ by a psp future homotopy flow. As a consequence, no point in $u \setminus y_1$ can be connected to a point on $y_1$ by a psp-future homotopy flow, since such a d-homotopy would move points on $y_2$ into $C$; and similarly when exchanging $y_1$ and $y_2$. Somewhat surprisingly, a psp future homotopy flow can “discover” the unreachable region, i.e. $u$ apart from its upper 1-cells. The resulting future pair component category $\vec{\pi}_0(S; +, \mathcal{F})^*$ of the “Swiss flag” $S$ does not give rise to further compression; it is the extension category of

$$
\begin{array}{ccc}
& b_1 \cup y_1 & \rightarrow C \\
& & \\
u & & \\
b_2 \cup y_2 & \rightarrow \\
& x_1 & \rightarrow d \\
A & \rightarrow & x_2
\end{array}
$$

where $x_i, y_i, b_i$ are half-open 1-cells, $d$ and $u$ contain only upper, resp. lower boundaries, and the lower und upper squares commute.

A similar procedure applies for the past pair component category $\vec{\pi}_0(S; -, \mathcal{F})^*$: just align $b_i$ with $x_i$ instead of $y_i$. For the total pair component category $\vec{\pi}_0(S; \pm, \mathcal{F})^*$, the (interiors of) the 1-cells $b_i$ give rise to separate components. For the neutral pair component category $\vec{\pi}_0(S; 0, \mathcal{F})^*$, the areas $x_i \cup b_i \cup y_i$ form one component.

### 4.3.3 Matchbox

The matchbox was discussed in Fahrenberg (2004) and has been a test case for various constructs concerning homological constructions. It can be represented as the boundary $\partial \square^3$ of a 3-box from which the interior of a lower face $\square^2$ has been removed. An equivalent description is given as the product of $\partial \square^2 \times I$ with an additional 2-cell $D$ glued in at the top. We will use the latter representation and we will reuse notation from Sect. 4.3.1 concerning $\partial \square^2$ in the following sense: Components from that case are replaced by their products with the half-open interval $[0, 1]$ – and path spaces have the same homotopy types as for $\partial \square^2$. In particular, only the pair $AC$ represents homotopy type $S^0$; all other pairs in the component category correspond to contractible path spaces. Nevertheless, compared to $\partial \square^2$, the (entire) cell $D$ gives rise
to additional components: There is no psp homotopy flow connecting a point from the complement of $D$ with $D$ itself: such a homotopy flow would push a path from $A$ to $C$ (corresponding to a non-contratible path space) to a path with target in $D$ – with a contractible path space.

As a consequence, additional components $AD, B_1D, B_2D, CD$ and $DD$ need to be added to the component categories of $\partial \square^2$ from Sect. 4.3.1, with obvious extension morphisms relating them to the other components and to each other.

### 4.3.4 Cubical “spheres” in higher dimensions

A cube in the cubical decomposition of the boundary of an $n$-box $\partial \square^n$ (the “cubical $(n - 1)$-sphere”) corresponds to an $n$-tuple $e := (e_1, \ldots, e_n)$ with $e_i \in \{0, 1, *)$, and $e \neq (*, \ldots, *)$. These $n$-tuples are partially ordered by the product order arising from $0 \leq * \leq 1$ apart from $(*, \ldots, *, 0_i, *, \ldots, *) \not\leq (*, \ldots, *, 1_i, *, \ldots, *)$. Let $\mathcal{P}_n$ denote the category representing that partial order (with $3^n - 1$ objects). Remark that $\partial \square^n$ can be obtained as a directed deformation retract of the Euclidean complex $[-1, 1]^n \cup \{0, 1\}^n$. Hence, as will be shown in Sect. 5.4, products of (reachable) open subcubes will be contained in the same component.

The homotopy types of trace spaces in $\partial \square^n$ were determined by Ziemiański (Ziemiański 2019): For $n$-tuples $e \leq f$, let $d_i = f_i - e_i$ (where we replace $*$ with 0.5). Let $n(e, f)$ denote the cardinality of the set $\{i|d_i = 1\}$.

**Lemma 8** (Ziemiański 2019) Let $e \leq f$. Then trace space $\overrightarrow{\mathcal{T}}(\partial \square^n)^e_f$ is contractible if there exists $i$ with $d_i = 0.5$, and homotopy equivalent to a sphere of dimension $n(e, f) - 2$ otherwise.

**Proposition 4** For $n > 2$, the component categories $\overrightarrow{T}_0(\partial \square^n; \alpha, \mathcal{F}_\infty)^*\alpha$, $\alpha \neq 0$, all agree with the extension category of the partial order category $\mathcal{P}_n$.

**Proof** The proof relies entirely on properties of (psp) homotopy flows established in Sect. 3.

1. For $k > 1$, a (neutral) psp homotopy flow leaves cells of the form $e_k = 0^k \cdot *^{n-k}$, resp. $f_k = 1^k \cdot *^{n-k}$ (regardless of the order of the coordinates) invariant; moreover, also their closures and complements. In fact, Lemma 8 shows that leaving one or both of the cells to the future (or the past) changes the homotopy type of $\overrightarrow{T}(\partial \square^n)^e_k$. Apply Lemma 3 and Lemma 5.

2. Now consider $k = 1$ and a cell $e_1$ of type $0^k *^{n-1}$: From 1. above and Corollary 1, we conclude that every psp future homotopy flow leaves the set $\bigcap \downarrow f^i_{n-1}$ invariant (with $f^i_{n-1} = (1, \ldots, 1, *_i, 1, \ldots, 1)$). This intersection is equal to the union of all cubes $e$ with no 1-coordinate at all (here we use $n > 2$!). But each cell of type $e_1$ is a maximal cube in that set with respect to the partial order. All cubes below $e_1$ are of type $e_k$, $k > 1$, and are thus invariant; cf 1. above. Hence $e_1$ is so, as well.

A cell of type $f_1 = 1^* *^{n-1}$ cannot be connected by a future psp flow with any of the (invariant) cubes in its future. Assume there is a psp future homotopy flow $H$ connecting one of the lower boundary cubes $10^i *^{n-i-1}$, $i > 0$, with $f_1$. Then,
using Lemma 6, $H$ would connect a cell of type $1^20^*n^{-3}$ with one of the invariant cells $f_k = 1^k\ast n^{-k}$, $k > 1$. Contradiction!

3. Now consider cubes of type $e = 0^i \ast j^1$, $i, j, k \geq 1$. Then $e$ is contained in the closure of a cube of type $0^i \ast n^{-i}$ (invariant by 1. and 2. above). We conclude from Lemma 4 that a psp future homotopy flow $H$ departing $e$ will end in a cube of type $0^i \ast j^1 n^{-i}$, $l \geq 0$. If $l > 0$, then Lemma 6 tells us that $H$ would connect a cube of type $\ast j^1 i^{-i}$ (invariant by 1. and 2. above) with a different cube. Contradiction! Likewise, a vertex $e$ of type $0^i \ast j^1 k$ with $i, j, k > 1$. Contradiction!

4. Since all cubes of the types considered in 3. above are invariant under a psp homotopy flow, none of them can be reached from another cube under a psp homotopy flow $H$ departing from a different cube in its past.

For past pair components, one may apply similar arguments - or consider the reverse d-space that is d-homeomorphic to the original one: Just exchange 0 s and 1s! □

Remark that the components in this case correspond to products of reachable components of the fundamental category considered in Fajstrup et al. (2004) (for $n = 3$) and for Ziemiański’s stable components (Ziemiański 2019).

### 4.4 Spaces with directed loops

#### 4.4.1 Directed circle

The directed circle $\overrightarrow{S^1}$ is the pre-cubical set with one 0-cell and one 1-cell. Its geometric realization $|\overrightarrow{S^1}|$ is a circle on which directed paths proceed counterclockwise, i.e., they are images of non-decreasing paths under the universal covering $\exp : \mathbb{R} \to |\overrightarrow{S^1}|$. All trace spaces $\overrightarrow{T}(\overrightarrow{S^1})^x_y$, $x, y \in S^1$, are homotopy equivalent to the discrete space indexed by the non-negative integers $\mathbb{N}_0$.

A directed degree one map $f : S^1 \to S^1$ homotopic to the identity induces a homotopy equivalence $\overrightarrow{T}(f) : \overrightarrow{T}(\overrightarrow{S^1})^x_y \to \overrightarrow{T}(\overrightarrow{S^1})^{fx}_{fy}$ on all trace spaces if and only if it is a directed homeomorphism: Since $f \simeq id$, it is onto. Assume $fx = fy = z$ for $x \neq y$. One of the counter-clockwise arcs from $x$ to $y$, resp. from $y$ to $x$ maps to a constant path, the other (without restriction the one from $y$ to $x$), to a d-path from $z$ to itself with winding number one. But then $\overrightarrow{T}(f) : \overrightarrow{T}(\overrightarrow{S^1})^x_y \to \overrightarrow{T}(\overrightarrow{S^1})^z_z$ misses the component given by constant maps!

For every two elements $x, y \in S^1$, there is a future psp homotopy flow $H$ of counterclockwise rotations (hence directed homeomorphisms) with $H_1(x) = y$. As a result, all pairs $(x, x)$ on the diagonal $\Delta$ are contained in the same component. The diagonal is of course invariant under any map. On the other hand, we have just seen that no pair $(x, y)$ in the complement $\Gamma = (S^1 \times S^1) \setminus \Delta$ can be connected to an element on the diagonal by a psp d-map (a homeomorphism)!
Let \((x, y), (x', y')\) denote two pairs in the complement \(\Gamma\) of the diagonal. After a rotation, we may assume that \(x = x'\). There is a directed homeomorphism (image of a piecewise linear map on \(\mathbb{R}\) under the exponential map) that fixes \(x\) and maps \(y\) into \(y'\) or \(y'\) into \(y\).

As a result, the future pair category of \(\pi_0(\widetilde{S^1}; +, \mathcal{F})_*\) has two objects given by the diagonal \(\Delta\) and its complement \(\Gamma := (S^1 \times S^1) \setminus \Delta\). Endomorphisms on both objects correspond to the non-negative integers \(\mathbb{N}_{\geq 0}\). The morphisms \(\text{Mor}(\Delta, \Gamma)\) correspond to \(\mathbb{N}_{\leq 0}\), as well, whereas \(\text{Mor}(\Gamma, \Delta)\) corresponds to the positive integers \(\mathbb{N}\); composition corresponds to addition. Note that \(\Delta\) and \(\Gamma\) are not isomorphic!

All other pair component categories \(\pi_0(\widetilde{S^1}; \alpha, \mathcal{F})_*\) are isomorphic among each other.

**Remark 4** 1. The result for the directed circle is slightly different from the one obtained in Raussen (2007) where we departed from the extension category of the fundamental category and localized weakly invertible extensions instead of \(d\)-maps.

2. Remark, that the pair component category does distinguish between a directed interval \(J \subset \mathbb{R}\) (Sect. 4.1.1) and the directed circle \(\widetilde{S^1}\).

### 4.4.2 Directed torus

Now consider the directed \(n\)-torus \(\mathbb{T}^n = (\tilde{S^1})^n, n \in \mathbb{N}\). All trace spaces \(\mathbb{T} (\mathbb{T}^n)\) are homotopy equivalent to a discrete space indexed by \(\mathbb{N}_{\geq 0}^n\). Let us again verify that a psp-\(d\)-map \(f\) homotopic to the identity is necessarily a homeomorphism. It must be onto since it preserves the fundamental homology class. Assume \(f(x) = f(y) = z\) for \(x, y \in \mathbb{T}^n, x \neq y\). Consider a \(d\)-path in \(\mathbb{T}^n\) from \(x\) via \(y\) to \(x\) of \(i\)-degree \(d_i = 0\) if \(x_i = y_i\) and \(d_i = 1\) if \(x_i \neq y_i\). The two pieces map under \(f\) to paths of multidegree \(\delta = (\delta_1, \ldots, \delta_n), \varepsilon = (\varepsilon_1, \ldots, \varepsilon_n)\) each; note that \(\delta_i + \varepsilon_i = (d_1, \ldots, d_n)\). The maps \(\mathbb{T} (f) : \mathbb{T} (\mathbb{T}^n)_x \rightarrow \mathbb{T} (\mathbb{T}^n)_{x'}\) and \(\mathbb{T} (f) : \mathbb{T} (\mathbb{T}^n)_y \rightarrow \mathbb{T} (\mathbb{T}^n)_{y'}\) have as image subsets whose homotopy types correspond to \(\delta + \mathbb{N}_{\geq 0}^n\), resp. \(\varepsilon + \mathbb{N}_{\geq 0}^n\). They cannot both be surjective, ie have image all homotopy types corresponding to \(\mathbb{N}_{\geq 0}^n\).

**Proposition 5** The pair component category \(\pi_0(\mathbb{T}^n; \alpha, \mathcal{F})_*\) is isomorphic to the product \(\prod_{i=1}^n \pi_0(\widetilde{S^1}; \alpha, \mathcal{F})_*\). This is a category with \(2^n\) objects in the set \(\{\Delta, \Gamma\}^n\). If one lets \(\Delta\) correspond to 0 and \(\Gamma\) to 1, and hence an object to a bit vector \(d \in \{0, 1\}^n\), then \(\text{Mor}(d, d')\) is a product of factors \(\mathbb{N}_{\geq 0}^n\) and \(\mathbb{N}\). A factor corresponds to \(\mathbb{N}\) exactly for pairs \((d_i, d'_i) = (1, 0)\). Composition corresponds to coordinatewise addition.

**Proof** According to Proposition 3, we need only show that the quotient functor from the product \(\prod_{i=1}^n \pi_0(\widetilde{S^1}; \alpha, \mathcal{F})_* \rightarrow \pi_0(\mathbb{T}^n; \alpha, \mathcal{F})_*\) is injective on objects, as well. To achieve this, we will show that every inessential \(d\)-map \(F : \mathbb{T}^n \rightarrow \mathbb{T}^n\) is a product of \(d\)-homeomorphisms \(f_i : \widetilde{S^1} \rightarrow \widetilde{S^1}, 1 \leq i \leq n\), ie \(F = f_1 \times \cdots \times f_n\).

Let \(F : \mathbb{T}^n \rightarrow \mathbb{T}^n\) denote an inessential \(d\)-map with \(F(x_1, x_2) = (y_1, y_2)\) and \(F(x_1, x_2) = (y'_1, y'_2), x_1, y_1, y'_1 \in S^1, x_2, y_2, y'_2 \in T^{n-1}\) and \(y_1 \neq y'_1\). (If we had an inessential map \(G : \mathbb{T}^n \rightarrow \mathbb{T}^n\) relating these pairs in the reverse direction, ...
we may consider $F = G^{-1}$ since $G$ has to be a directed homeomorphism). After a coordinatewise rotation, we may assume that $(y_1, y_2) = (x_1, x_2)$ – and $y'_1 \neq x_1$. Let $\sigma = (c_{x_1}, \sigma_2)$ denote a $d$-path from $(x_1, x'_2)$ to $(x_1, x_2)$, constant in the first variable. Consider the induced diagram of path spaces

$$
\begin{align*}
\overrightarrow{P}(\overrightarrow{T}^n; (x_1, x_2)) & \xrightarrow{\ast F(\sigma)} \overrightarrow{P}(\overrightarrow{T}^n; (x_1, x_2)) \\
\overrightarrow{T}(F) & \xleftarrow{\ast \sigma} \overrightarrow{T}(F) \\
\overrightarrow{P}(\overrightarrow{T}^n; (x_1, x_2)) & \xrightarrow{\ast \sigma} \overrightarrow{P}(\overrightarrow{T}^n; (x_1, x_2)) \\
\Omega(T^n; (x_1, x_2)) & \xrightarrow{\Omega(F)} \Omega(T^n; (x_1, x_2))
\end{align*}
$$

The image of the lower extension map $\ast \sigma$ contains loops of multidegree $(0, d)$. The image of the upper extension map $\ast F(\sigma)$ map can only contain loops of multidegree $(d_1, d)$ with $d_1 > 0$. This contradicts the fact that an endo map on $T^n$ that is homotopic to the identity has to preserve multidegrees. □

**Remark 5** In contrast to what happens to previously considered component categories of the fundamental category (Fajstrup et al. 2004; Goubault and Haucourt 2007), this example shows that localized and component categories constructed from pair categories by localizing the effects of psp-d-maps make sense also for $d$-spaces with non-trivial directed loops.

We postpone the investigation of the pair component categories for the $d$-space corresponding to Dubut’s example to Sect. 5.5.

## 5 Pre-cubical sets and order pair components

In general, it seems to be hard to determine the pair component categories introduced in Sect. 2.3.4 algorithmically. For pre-cubical sets, cf Sect. 3.3.1, we will now define and describe a related finer component category that arises by inverting fewer morphisms and that is easier to comprehend and to determine.

### 5.1 Interval induced maps on a pre-cubical set

The following construction is essentially contained in Zmiański (2019): Let $h : [0,1] \to [0,1]$ denote a reparametrization of the unit interval $I$, i.e., a non-decreasing and surjective continuous map. All such reparametrizations form a convex and hence contractible space (in the topology inherited from the compact-open topology). The homeomorphisms within the reparametrizations (the strictly increasing ones) form likewise a convex and hence contractible subspace. Particular reparametrizations are of future type if $h(t) \geq t$ for all $t \in I$, resp. of past type if $h(t) \leq t$, $t \in I$. Algebraically, interval reparametrizations form a monoid under composition (with those of future, resp. past type as submonoid) and homeomorphisms form a group (with subgroups of future, resp. past type).
Consider a pre-cubical set $X$. Every interval reparametrization $h$ can be used to construct an endo-d-map $h_X$ on the geometric realization $|X|$ defined by $[c, (t_1, \ldots, t_n)] \mapsto [c; (ht_1, \ldots, ht_n)]$. By definition, $h_X$ is a cube-preserving map. It is well-defined with respect to the boundary relations on $X$; for this to be true, in general, it is necessary to use the same reparametrization $h$ on each coordinate.

An endo-d-map $h$ in $X$ will be called interval induced if it can be described as $h_X$ for a suitable interval reparametrization $h$.

**Remark 6**

1. For a Euclidean complex, cf Sect. 5.4, one may be less careful and select different reparametrizations for each of the $n$ coordinates.
2. If $h$ is a homeomorphic d-map with inverse $h^{-1}$, then $h_X$ and $(h^{-1})_X = h_X^{-1}$ are inverse homeomorphic endo-d-maps.
3. It is clear that the interval induced endo-d-maps on $X$ form a submonoid of the monoid $d(X)$ of all endo-d-maps; the interval induced endo-d-homeomorphisms on $X$ form a subgroup $\Sigma_\alpha^d(X)$ of the group of all endo-d-homeomorphisms.

**Lemma 9**

An interval induced endo-d-map $h_X$ induced by an interval homeomorphism $h$ is neutrally inessential. If it is of future type (resp. past type), it is future (resp. past) inessential: $\Sigma_\alpha^d(X) \subset \Sigma_\alpha^d(X)$.

**Proof**

A linear reparametrization homotopy $H : \widehat{T} \times I \rightarrow \widehat{T}$ arises by convex combination of the identity map $id_I$ and the chosen reparametrization $h$. It consists of d-maps $H_t$, and it is an increasing/decreasing homotopy (in the $I$-variable) if $h$ is of future, resp. of past type. The homotopy $H$ induces the homotopy flow $H_X : X \times I \rightarrow X$ given by $H_X([c, e], t) = ([c, H(e(t))])$ on $X$ ending at $h_X$.

If $h$ is a homeomorphism (i.e. injective), it induces a neutral, future, resp. a past homotopy flow $H_X : X \times I \rightarrow X$, $H_X(-, t) = (H_t)_X(-)$ that consists of d-homeomorphisms; in particular, of homotopy equivalences. Each induced map $(H_t)_X : X \rightarrow X$ induces thus homeomorphisms on path and trace spaces (with the map induced by the inverse homeomorphism as inverse). Hence it is $\mathcal{F}$-inessential. \hfill $\Box$

**Question**

Is the statement in Lemma 9 true for general interval induced endo-d-maps?

Like in Sect. 2.3.4, the monoid $\Sigma_{\alpha}^d(X)$ of $\alpha$-interval induced d-maps on $X$, $\alpha = +, -, 0, \pm$, gives rise to wide subcategories (same pair objects) $\Sigma_{\alpha}^d(X) \subset \Sigma_{\alpha}^d(X) \subset d(X)$ resp. $\Sigma_{\alpha}^dE\overline{\mathcal{P}}_1(X) \subset \Sigma_{\alpha}^dE\overline{\mathcal{P}}_1(X) \subset dE\overline{\mathcal{P}}_1(X)$. In the remaining part of the paper, we will focus on the localized category $\Sigma_{\alpha}^dE\overline{\mathcal{P}}_1(X)[\Sigma_{\alpha}^d(X)^{-1}]$ and the (pair) component category, denoted $\overline{\mathcal{P}}_0(X; \alpha, \mathcal{F})^*_\ast$.

The inclusion of inverted subcategories $\Sigma_{\alpha}^d(X) \subset \Sigma_{\alpha}^d(X)$ gives rise to quotient functors $\Sigma_{\alpha}^dE\overline{\mathcal{P}}_1(X)[\Sigma_{\alpha}^d(X)^{-1}] \rightarrow \Sigma_{\alpha}^dE\overline{\mathcal{P}}_1(X)[\Sigma_{\alpha}^d(X)^{-1}]$ between localized categories resp. $\overline{\mathcal{P}}_0(X; \alpha, \mathcal{F})^*_\ast \rightarrow \overline{\mathcal{P}}_0(X; \alpha, \mathcal{F})^*_\ast$ between quotient categories. In the following, we will show that, for a finite pre-cubical set $X$, the “finer” category $\overline{\mathcal{P}}_0(X; \alpha, \mathcal{F})^*_\ast$ has finitely many objects and conclude that this also holds for the pair component categories $\overline{\mathcal{P}}_0(X; \alpha, \mathcal{F})^*_\ast$. 

Springer
5.2 Order equivalence and order pair components

Definition 6 1. Two vectors \( z = [z_i], z' = [z'_i] \in \mathbb{R}^k \) are called order equivalent if and only if \( z_i R z_j \iff z'_i R z'_j \) for all \( 1 \leq i, j \leq k \) and \( R \in \{<, =, >\} \).
2. Let \( x, x' \in \mathbb{R}^n \), \( y, y' \in \mathbb{R}^m \). The pairs \((x, y)\) and \((x', y')\) are called order equivalent if and only if the vectors \([x, y]\) and \([x', y']\) \(\in \mathbb{R}^{n+m}\) are order equivalent.

Lemma 10 1. Two vectors \( z = [z_i], z' = [z'_i] \in \mathbb{R}^k \) are order equivalent if and only if there exists a \(d\)-homeomorphism \( h : I \to I \) with \( h(z_i) = z'_i \).
2. Let \( X \) denote a pre-cubical set with an \(n\)-cell \(c\) and an \(m\)-cell \(d\). Let \( x, x' \in I^n, y, y' \in I^m \) such that \((x, y)\) and \((x', y')\) are order equivalent. Then there exists an interval induced \(d\)-homeomorphism \( h_X \) with \( h_X([c, x]) = ([c, x']) \) and \( h_X([d, y]) = [d, y'] \).

Proof A \(d\)-homeomorphism \( h \) produces clearly order equivalent vectors \( z = [z_i] \) and \( z' = [hz_i] \). Given order equivalent vectors \( z, z' \), one may choose a piecewise linear \(d\)-homeomorphism with \( h(z_i) = z'_i \). (2) follows from (1).

The following lemma concerning least upper bounds \( x \lor x' \) resp. greatest lower bounds \( x \land x' \) is straightforward:

Lemma 11 If two pairs \((x, y)\) and \((x', y')\) are order equivalent, then they are both order equivalent to their least upper bounds \((x \lor x', y \lor y')\) and greatest lower bounds \((x \land x', y \land y')\), as well. As a consequence

1. There exists a \((\Sigma^+_{\alpha})\)-zig-zag morphism \((x, y) \to (x \lor x', y \lor y') \leftarrow (x', y')\).
2. There exists a \((\Sigma^-_{\alpha})\)-zig-zag-morphism \((x, y) \leftarrow (x \land x', y \land y') \to (x', y')\).

Proposition 6 Let \( X \) denote a pre-cubical set with an \(n\)-cell \(c\) and an \(m\)-cell \(d\). Let \( x, x' \in I^n \) and \( y, y' \in I^m \).

1. If the pairs \((x, y)\) and \((x', y')\) are order equivalent, then the pairs \([[c, x], [d, y]]\) and \([[c, x'], [d, y']]\) are situated in the same component in \( \overline{\pi}_0(X; \alpha, \mathcal{S})^* \) for all \( \alpha \) and hence also in \( \overline{\pi}_0(X; \alpha, \mathcal{F})^* \), for all \( \alpha \) and \( \mathcal{F} \). In particular, \( \overline{T}(X)_{[c,x]}^{[d,y]} \) and \( \overline{T}(X)_{[c,x']}^{[d,y']} \) are homeomorphic and thus homotopy equivalent.
2. If the pairs \([[c, x], [d, y]]\) and \([[c, x'], [d, y']]\) are contained in the same component object in the component category \( \overline{\pi}_0(X; \alpha, \mathcal{S})^* \), then \((x, y)\) and \((x', y')\) are order equivalent.
3. The order pair categories \( \overline{\pi}_0(X; \alpha, \mathcal{S})^*, \alpha \in \{+, -, \pm, 0\} \), agree and will be denoted just by \( \overline{\pi}_0(X; \mathcal{S})^* \).

Proof This follows immediately from Lemmas 10 and 11.

5.3 Order subdivisions and the order pair component category

Proposition 6 allows to give fairly explicit descriptions of the order pair category \( \overline{\pi}_0(X; \mathcal{S})^* \) of a pre-cubical set \( X \): A cube \( I^k \) subdivides into \( k \)-simplices given
by inequalities $0 \leq x_{ij} \leq x_{i2} \leq \cdots \leq x_{ik} \leq 1$; there are $k!$ such simplices. All possible order relations between coordinates arise by replacing $\leq$ by either $=$ or by $<$; each replacement (ie each ordered partition) gives rise to interiors $\Delta$ of sub simplices $\Delta$ of this subdivision. If $k = n + m$, inclusions $[1 : n] \hookrightarrow [1 : n + m]$, resp. $[1 : m] \hookrightarrow [1 : n + m]$ induce simplicial projections $I^{n+m} \to I^n$ resp. $I^{n+m} \to I^m$ (by restriction of a partition to $n$, resp. $m$ coordinates).

To get hold on an object in the order pair category $\overrightarrow{\pi}_0(X; \mathcal{F})^\ast_n$ of $X$, you need to fix a pair of cubes $c \in X_n, d \in X_m$ and the interior of a subsimplex $\Delta^d_c$ of the simplicial subdivision of $|c| \times |d| \cong I^{n+m}$ just described. Furthermore, you need to make sure that there exist $(s, t) \in \Delta^d_c$ such that $\overrightarrow{\pi}(X)_{[c,s]} \neq \emptyset$. By Proposition 6, this condition is independent of the choice of base points $s, t$ in $\Delta^d_c$; for example, one may choose the barycenters of each subsimplex $\Delta^d_c$. But beware: These do, in general, not agree with the pair of barycentres of its projections within $I^n$, resp. $I^m$.

**Future (extension) morphisms** from $\Delta^d_c$ to $\Delta^d_{c'}$ are determined by $\overrightarrow{\pi}_1(X)_{[d,t]}^\prime$ for $(t, t') \in \Delta^d_c$ and $\overrightarrow{\pi}(X)_{[d,t]} \neq \emptyset$; well-determined up to natural homeomorphisms by Lemma 11. Composition of future morphisms arises from composition in the fundamental category between matching representatives; you may have to change base point pairs by an element of $\Sigma_{\mathcal{F}}(X)$ before representatives match! Similarly for past morphisms.

**Remark 7** The path space between two points in the same cube is contractible or empty; this is in particular true for path spaces between barycenters of a subdivision simplex and a boundary simplex. Hence, there is at most one morphism between neighbouring cells given by an extension morphism contained in these two cells.

By construction, the functor $\overrightarrow{\pi}_1(X)^\ast_n : dE \overrightarrow{\pi}_1(X) \to \text{Ho} - \text{Top}$ from Sect. 2.1.3 extends to $dE \overrightarrow{\pi}_1(X)[\Sigma_{\mathcal{F}}(X)^{-1}]$; its restriction to $\Sigma_{\mathcal{F}} E \overrightarrow{\pi}_1(X)[\Sigma_{\mathcal{F}}(X)^{-1}]$ (analogous to the construction in Sect. 2.3.1) factors over the quotient category $\overrightarrow{\pi}_0(X; \mathcal{F})^\ast_n$. The quotient functors $\overrightarrow{\pi}_0(X; \mathcal{F})^\ast_n \to \overrightarrow{\pi}_0(X; \alpha, \mathcal{F})^\ast_n$, $\alpha = +, -, 0, \pm$, from Sect. 5.1 are all surjective on objects and full; but rarely faithful.

For a finite-dimensional pre-cubical set $X$, the order pair component can be “over-approximated” by a discrete full subcategory of $E \overrightarrow{\pi}_1(X)$. For an $n$-dimensional complex $X$, we choose as objects all pairs $[c, s], [d, t]$ such that all coordinates $s_i$ of $s$ and $t_j$ of $t$ are fractions $\frac{l}{2n+1}$, $0 \leq l \leq 2n + 1$. This choice ensures that every subsimplex $\Delta^d_c$ contains at least one such pair. The projection functor from the arising subcategory of $E \overrightarrow{\pi}_1(X)$ into $\overrightarrow{\pi}_0(X; \mathcal{F})^\ast_n$ is onto on objects and fully faithful, hence an equivalence of categories. Using Remark 7 for 2. below, we conclude:

**Corollary 3** Let $X$ denote a finite pre-cubical set.

1. $\overrightarrow{\pi}_0(X; \mathcal{F})^\ast_n$ and thus all pair component categories $\overrightarrow{\pi}_0(X; \alpha, \mathcal{F})^\ast_n$ have finitely many objects.
2. If $X$ does not admit any non-trivial directed loops, then all the above mentioned categories have finite sets of morphisms.
5.4 Euclidean cubical complexes

With the lattice of integer vectors \( \mathbb{Z}^n \subset \mathbb{R}^n \) as vertices, one forms an infinite pre-cubical set whose geometric realization is \( \mathbb{R}^n \). Every subcomplex \( X \) of that complex is called a Euclidean cubical complex. By definition, such a Euclidean complex admits only trivial directed loops.

**Definition 7**

1. Two elements \((x, x') \in X\) will be called *cube-equivalent* if there exists a cube \( c \subset X \) such that \( x, x' \) are both contained in the interior of \( c \).
2. A d-map \( h = (h_1, \ldots, h_n) : \mathbb{R}^n \to \mathbb{R}^n \) with \( h_i(x_1, \ldots, x_i, \ldots, x_n) = x_i \) for every \( x_i \in \mathbb{Z}, 1 \leq i \leq n \), is called *cube-preserving*.
3. For \( h(x) \geq x \) (resp. \( h(x) \leq x \)), \( h \) is said of future type, resp. of past type.
4. A cube-preserving d-map \( h \) restricts to a cellular endo-d-map \( h : X \to X \) from every subcomplex \( X \) into itself. These cube-preserving maps form, when restricted to \( X \), a (contractible!) monoid. Those of future (resp. past) type form contractible submonoids \( H^\alpha_n(X) \).

**Proposition 7**

Let \( X \) denote a Euclidean cubical complex. Any cube preserving d-map \( h : X \to X \) of future type (resp. of past type) is \(+F_\infty\) (resp. \(-F_\infty\)) inessential.

**Proof**

Cellwise convex combination between \( id_X \) and \( h \) defines a homotopy flow \( H \) such that every d-map \( H_t : X \to X \) is cube-preserving, as well. It is a future (resp. past) homotopy flow if \( h \) is of future (resp. past) type. It is therefore enough to show that an \( \alpha \) cube-preserving map \( h : X \to X \) is \( F\text{-psp}; \) we do that for \( \alpha = + \):

According to Remark 1.5 [cf also (Raussen 2007, (5.3))], the diagram

\[
\begin{array}{ccc}
T(X)^y_x & \xrightarrow{T(h)} & T(X)^{h(y)}_{h(x)} \\
*H(y) & & H(x)* \\
\downarrow & & \downarrow \\
T(X)^{h(y)}_{h(x)} & \xrightarrow{T(h)} & T(X)^y_x
\end{array}
\]

is homotopy commutative for \((x, y) \in X^2\). Hence it is enough to show that for every \((x, y) \in X^2\) and every d-path

1. \( \sigma \) from \( y \) to \( y' \) between cube-related elements, the map \( *\sigma : \overline{P}(X)^y_x \to \overline{P}(X)^{y'}_x \)
2. \( \tau \) from \( x' \) to \( x \) between cube-related elements, the map \( \tau* : \overline{P}(X)^y_x \to \overline{P}(X)^{y'}_x \)

are homotopy equivalences. (The construction makes uses of paths instead of traces, but the naturalization map between traces and d-paths in Euclidean complexes from Raussen (2009) is a homotopy equivalence.) We prove 1. above; the proof of 2. is similar.

A map \( M^y : \overline{P}(X)^y_x \to \overline{P}(X)^y_x \) is constructed by assigning to \( \alpha \in \overline{P}(X)^y_x \) the d-path \( \alpha^y \in \overline{P}(X)^y_x \), \( \alpha^y(t) = \alpha(t) \land y \), i.e. \( \alpha_i^y(t) = \min(\alpha_i(t), y_i) \). Since \( y \) and \( y' \) are cube-related, \( \alpha(t) \) and \( \alpha^y(t) \) are, for every \( t \in I \), contained in the same subcube of \( \mathbb{R}^n \), and hence \( \alpha^y \) is a d-path in \( X \).
The composition $\overrightarrow{P}(X)^y \xrightarrow{\alpha \sigma} \overrightarrow{P}(X)^y \xrightarrow{M} \overrightarrow{P}(X)^y$ assigns to $\alpha \in \overrightarrow{P}(X)^y$ the path $\alpha \ast c_y$, which is homotopic to the identity map.

For $s \in I$, let $\sigma^s$ denote the d-path $\sigma^s(t) := (s + (1 - s)t)$ from $\sigma(s)$ to $\sigma(1) = y'$. We consider the homotopy $\overrightarrow{P}(X)^y \times I \xrightarrow{M \sigma^s} \overrightarrow{P}(X)^y$ (with parameter $s$); it deforms the map $\ast \sigma \circ M^y$ — for $s = 0$ — into $\ast c_y'$ — for $s = 1$. The latter map sends $\alpha \in \overrightarrow{P}(X)^y$ into $\alpha \ast c_y'$, and it is homotopic to the identity map on $\overrightarrow{P}(X)^y$.

Proceeding as in Sect. 5.1, the monoids from Definition 7 give rise to wide subcategories $\Sigma^e_{\mathscr{H}_0}(X) \subset d(X \subset dE \overrightarrow{\mathfrak{P}}_1(X), \alpha = +, -, 0, \pm$. We can form the localized categories $\Sigma^e_{\mathscr{H}_0} E \overrightarrow{\mathfrak{P}}_1(X)[\Sigma^e_{\mathscr{H}_0}(X)^{-1}]$, their quotient categories $\overrightarrow{\mathfrak{P}}_0(X; \alpha, \mathscr{H}_0)^*$ and, using Proposition 7, quotient functors into $\overrightarrow{\mathfrak{P}}_0(X; \alpha, \mathscr{P})^*$, at least for $\alpha \neq 0$.

Proposition 6 has the following (far simpler) analogue for Euclidean cubical complexes:

**Proposition 8** Let $X$ denote a Euclidean complex and let $(x, y)$, $(x', y') \in X^2$.

1. If $(x, x')$ and $(y, y')$ are cube equivalent, then $(x, y)$ and $(x', y')$ are situated in the same component object in $\overrightarrow{\mathfrak{P}}_0(X; \alpha, \mathscr{H}_0)^*$. In particular, $\overrightarrow{T}(X)^y$ and $\overrightarrow{T}(X)^{y'}$ are homotopy equivalent.
2. If the pairs $(x, y)$ and $(x', y')$ are situated in the same component object in the component category $\overrightarrow{\mathfrak{P}}_0(X; \alpha, \mathscr{H}_0)^*$, then $(x, x')$ and $(y, y')$ are cube equivalent.
3. The pair categories $\overrightarrow{\mathfrak{P}}_0(X; \alpha, \mathscr{H}_0)^*$, $\alpha \in \{+, -, \pm, 0\}$, agree and will be denoted just by $\overrightarrow{\mathfrak{P}}_0(X, \mathscr{H}_0)^*$. There are quotient functors $\overrightarrow{\mathfrak{P}}_0(X; \alpha, \mathscr{P})^* \rightarrow \overrightarrow{\mathfrak{P}}_0(X; \alpha, \mathscr{P})^*$ for all $\alpha$.

For the proof of Proposition 8, we need the following lemma. We will write $(x, y) \sim_{\mathscr{H}} (x', y')$ if they are contained in the same component; here for $\alpha = +$. We shall write $x \prec \prec x'$ if $x_i < x_i'$ for all $i$.

**Lemma 12** 1. Let $x, x''$ be cube-related and $x'' \prec \prec x$. Let $(x, y) \in X^2$.

Then $(x'', y) \sim_{\mathscr{H}} (x, y)$.

2. Let $y, y''$ be cube-related, $(x'', y) \in X^2$, $y'' \prec \prec y$. Then $(x'', y) \sim_{\mathscr{H}} (x'', y'')$.

**Proof of Lemma 12** To show 1., we construct a cube-preserving d-map $h = h_{1} \times \ldots \times h_{n} : \mathbb{R}^n \rightarrow \mathbb{R}^n$ (of future type) with $h(x'') = x$ and $h(y) = y$ as product of piecewise linear d-maps $h_i$, $1 \leq i \leq n$, given by

$$h_i(t) = \begin{cases} t & t \leq [x_i] \text{ or } t \geq \max \{y_i, [x_i] + 1\} \\ x_i' & t = x_i'' \end{cases}$$

by assumption $x_i'' < y_i$. To show 2., a similarly constructed cube-preserving d-map fixes $x''$ and sends $y$ into $y''$. \qed
**Proof of Proposition 8** 1. Choose $x'' << x, x'$ in the interior of the same cell as $x$ and $y, y' << y''$ in the same cell as $y$. According to Lemma 12, we obtain the following chain of equivalences:

$(x, y) \sim_{H} (x'', y) \sim_{H} (x'', y'') \sim_{H} (x', y')$.

A similar construction works for $\alpha = -$.

2. It is obvious, since d-maps in $\mathcal{H}_n$ preserve (interiors of) cubes.

3. follows from 1. and 2. \hfill \Box

**Corollary 4** Let $X \subset \mathbb{R}^n$ denote a Euclidean cubical complex.

1. Components in $\overrightarrow{\pi}_0(X, \mathcal{H}_n)^*_\alpha$ can be indexed by reachable pairs of cubes $(c, d)$.
2. The category $\overrightarrow{\pi}_0(X, \mathcal{H}_n)^*_\alpha$ is isomorphic to the full subcategory of $E \overrightarrow{\pi}_1(X)$ the objects of which are the pairs of barycenters of reachable cubes.
3. Components in each of the categories $\overrightarrow{\pi}_0(X, \mathcal{H}_n)^*_\alpha$ and hence $\overrightarrow{\pi}_0(X; \alpha, \mathcal{F})^*_\alpha$ have finitely many objects and morphisms.

**Remark 8** Contrary to what happens for general cubical complexes, for Euclidean cubical complexes we can, as in the proof of Proposition 8, construct inessential endo-d-maps fixing just one of the end points and leading to inessential extension morphisms; compare Lemma 1.4. This is the reason why, for these complexes, it may be unnecessary to distinguish between effects of inessential d-maps and of inessential extensions, as they were used in previous work on component categories (Fajstrup et al. 2004; Goubault and Haucourt 2007).

### 5.5 Dubut’s example revisited

Finally, we analyze component categories in the case of the cubical complex $D$ from Sect. 1.2, which is not a Euclidean complex. Nevertheless, some of the tools from the preceding sections come in helpful. It turns out that in this case, the $\alpha, \mathcal{F}$-inessential d-maps fixing just one of the end points and leading to inessential extension morphisms; compare Lemma 1.4. This is the reason why, for these complexes, it may be unnecessary to distinguish between effects of inessential d-maps and of inessential extensions, as they were used in previous work on component categories (Fajstrup et al. 2004; Goubault and Haucourt 2007).

**Proposition 9** A $+ \mathcal{F}$-inessential d-map $f : D \rightarrow D$ has the following properties:

1. $f$ preserves $a_i$, $i = 1, 2, a^+$, $D \backslash A, C, B_1 \cup b_1 \cup C, B_2 \cup b_2 \cup C$.
2. The restrictions of $f$ to $A$ and to $C$ agree, ie $f([A; (x_1, x_2)]) = f([C; (x_1, x_2)]), x_1, x_2 \in I$. 

\[ Springer \]
3. On $A$, resp. on $C$, $f = f|_A = f|_C$ is a product map $f = f_1 \times f_2$ for suitable $d$-maps $f_i : \mathcal{T} \to \mathcal{T}$ that satisfy $t \leq f_i(t), t \in I$.

4. These $d$-maps $f_i$ are $d$-homeomorphisms $f_i : [0, 1] \to [d_i, 1]$ for some $0 \leq d_i < 1$.

5. There are $d$-maps $g_i : I^2 \to [0, 1 + d_i], i = 1, 2$, with $g_1(0, t) = 0 = g_2(t, 0), g_1(1, t) = d_1, g_2(t, 1) = d_2$ and $(s, t) \leq g_i(s, t), i = 1, 2$, such that $f([B_1; (x_1, x_2)]) = [B_1 \cup C; (g_1(x_1, x_2), f_2(x_2))]$ and $f([B_2; (x_1, x_2)]) = [B_2 \cup C; (f_1(x_1), g_2(x_1, x_2))]$ with $f_1, f_2$ as in (3) above.

6. $f$ preserves $\cup A, c^+, b_1 \cup c_2, b_2 \cup c_1, \cup B_1 \cup \cup C, \cup B_2 \cup \cup C$.

**Proof**

1. The vertex $a^+$ is a future branch point. By Corollary 1.1, both that point, its past $\downarrow a^+ = A$ and the complement of $A$ are preserved. Moreover, $f$ preserves $\uparrow a \cap \downarrow a^+ = a_i$ and $C = \uparrow C$. Also the subsets $\cup B_1 \cup B_1 \cup C$ and $\cup B_2 \cup B_2 \cup C$ are equal to their own future.

2. For a chosen point $[C; (y_1, y_2)]$, we consider the set of all points $[A; (x_1, x_2)]$ in its past $\downarrow [C; (y_1, y_2)]$ and decompose it according to whether $(x_1, x_2)$ belongs to $Q_0(y_1, y_2) = [0, y_1] \times [0, y_2]$. For $(x_1, x_2) \in Q_0(y_1, y_2)$, trace space $\mathcal{T}(D)_{[A;x_1, x_2]}$ has two path components.

$Q_1(y_1, y_2) = [y_1, 1] \times [0, y_2]$. For $(x_1, x_2) \in Q_1(y_1, y_2)$, trace space $\mathcal{T}(D)_{[A;x_1, x_2]}$ is path-connected; all paths in it intersect $B_1 \setminus a^+$, but not $B_2 \setminus a^+$. Let $f([C; (x_1, x_2)]) = [C; (y_1, y_2)]$. Since $f$ is a psp $d$-map, its restriction $f_A$ to $A$ must map $Q_j(x_1, x_2)$ into $Q_j(y_1, y_2), j = 1, 2, 3$. By continuity, it maps the one point set $\{(x_1, x_2)\}$ to $\mathcal{T}(D)_{[A;x_1, x_2]}$.

3. The horizontal $d$-path from $[A; (0, x_2)]$ to $[C; (0, x_2)]$ through $B_1$ maps under $f$ to the horizontal $d$-path from $[A; f(0, x_2)]$ to $[C; f(0, x_2)]$ through $B_1$; in particular, $f_2(t, x_2) = f_2(0, x_2)$ for $t \in I$. Likewise for $f_1$ using vertical $d$-paths through $B_2$. The existence of a future $d$-homotopy from $id_D$ to $f$ requires $t \leq f_i(t), t \in I$. 

\[ \square \]
4. By (1) above, \( f_i(1) = 1, \ i = 1, 2 \). Let \( d_i := f_i(0) \geq 0 \). Assume there exists \( 0 \leq x_1 < x'_1 \leq 1 \) with \( f_1(x_1) = f_1(x'_1) \). Then, for every \( x_2 \in I \), the space \( \overrightarrow{T}(D_{[A; (x_1, x_2)]}^{[C; (f_1(x_1), f_2(x_2))]} \) has one component whereas \( \overrightarrow{T}(D_{[A; (x'_1, x_2)]}^{[C; (f_1(x'_1), f_2(x_2))]} \) has two. Hence \( f \) cannot be psp.

Similarly for \( f_2 \).

5. The second component of \( f|_{B_1} \) does not depend on \( x_1 \) and is equal to \( f_2 \) since 
\[
  f_2(x_2) = f_2([A; (x_1, x_2)]) = f_2([B_1; (x_1, x_2)]) = f_2([C; (x_1, x_2)]) = f_2(x_2), \ x_1 \in I.
\]

6. Since \( f_i \) is a homeomorphism, it preserves the upper boundary \( 1 \) and its complement.

Like in Sect. 5.1, but now with a coherent prescribed order on the first and second coordinate, we may compare coordinates of start and end points by the relations \( =, <, > \). For example, a decoration \((=,<)\) indicates that the first coordinates of start and end point agree whereas the second coordinate of the start point is less than the second coordinate of the end point.

**Proposition 10** The pair component category \( \mathcal{B}_0(D; +, \mathcal{F}) \) has – independently of \( \mathcal{F} \) – objects of the form: Reachable pairs in

1. \((A, \cup A)\) with decorations \((\Rightarrow), (=<), (<=)\) and \((<<)\);
2. \((A, a_i), \ i = 1, 2\); with decorations \(=\) and \(<\) in one coordinate;
3. \((A, a^+)\);
4. \((a_i, a_i), \ i = 1, 2\); with decorations \(<\) and \(=\);
5. \((a_i, a^+), \ i = 1, 2\);
6. \((a^+, a^+)\);
7. \((A, \cup C)\) with decorations \((<<), (<=), (=<), (\Rightarrow)\);
8. \((A, B_1 \cup C)\) with decorations \((<>), (>\Rightarrow)\);
9. \((A, B_2 \cup C)\) with decorations \((<<), (>\Rightarrow)\);
10. \((A, (b_1 \cup c_2))\) and \((A, (b_2 \cup c_1))\);
11. \((A, c^+)\);
12. \((a_i, B_1 \cup C), \ i = 1, 2\); with decorations \(=\) and \(<\);
13. \((a_i, b_1 \cup c_2), (a_i, b_2 \cup c_1), (a_i, c^+), \ i = 1, 2\);
14. \((a^+, b_1 \cup c_2), (a^+, b_2 \cup c_1), (a^+, c^+)\);
15. \((B_1 \cup B_2 \cup C), B_1 \cup B_2 \cup \cup C)\) – no decorations;
16. \((B_1 \cup C, b_1 \cup c_2), B_2 \cup C, b_2 \cup c_1)\);
17. \((B_1 \cup C, c^+)\), \(B_2 \cup \cup C, c^+)\);
18. \((b_1 \cup c_2, b_1 \cup c_2), (b_2 \cup c_1, b_2 \cup c_1)\);
19. \((b_1 \cup c_2, c^+), (b_2 \cup c_1, c^+)\);
20. \((c^+, c^+)\)

and the inherited extension morphisms.

**Proof** Most of the distinctions follow from the fact that \( f|_{A} = f|_{C} = f_1 \times f_2 \) is a product of homeomorphisms, hence points with non-equal coordinates cannot be identified with points with equal coordinates (unlike what may happen for a homotopy equivalence). To construct a psp-d-map \( f : D \rightarrow D \) establishing equivalence of pairs
of points in one of the equivalence classes, one may choose 0 ≤ d_i < 1 and d-homeomorphisms f_i : [0, 1] → [d_i, 1], i = 1, 2, with t ≤ f_i(t), t ∈ I and use them to define the map f on A ∪ C according to Proposition 9.2–4. To extend that map to the remaining cells, choose d-maps g_i : I^2 → [0, 1 + d_i] as in Proposition 9.5. and define f on B_1 ∪ B_2 accordingly. A linear future d-homotopy connects id_D with the resulting endo map f on D. In general, a zig-zag of such d-homotopies is needed.

It may be a bit surprising that decorations do not turn up in case 15. One may extend a map f_i : [0, 1] → [d_i, 1] from Proposition 9.4 to d-maps g_i : [−1, 1] → [−1, 1] (for the first coordinate on B_1, resp. the second on B_2); this map needs only be injective on [0, 1]. Using such maps, we establish that two pairs [C; (c_1, c_2), (c_1, c_2)] and [C; (c_1, c_2), (c_1', c_2')] are F-equivalent as follows:

[C; (c_1, c_2), (c_1, c_2)] ∼ [B_1; (b_1, c_2), (b_1', c_2)] ∼ [C; (c_1, c_2), (c_1', c_2)]

∼ [B_2; (c_1, b_2), (c_1, b_2')] ∼ [C; (c_1, c_2), (c_1', c_2')].

This implies that all pairs in C^2 are equivalent to each other, and hence all pairs in case 15.

Remark that inessential + F maps do not preserve all cells; hence π_0(D; +, F) has fewer component objects than π_0(D, H^2)*, cf Sect. 5.4.

For α = −, a similar case-by-case examination exhibits components of type (C, C) with decorations; this time, start points in A ∪ B_i can be fused. For α = ±, the subsets B_i cannot be fused with neither A nor C.

6 Conclusion and future work

6.1 Summary

Inessential homotopy flows and inessential d-maps yield a coherent framework for comparing path spaces with variable end points within a given directed space. Localizing their contribution to categories with pairs of points as objects transforms them into isomorphisms; this is justified since the trace space functor lets them correspond to isomorphisms in the homotopy category. The resulting quotient categories were shown to have finitely many (though often a huge number of) objects when the underlying directed space is a finite cubical complex, even if the space admits directed loops. In many examples, in particular for the example from Sect. 1.2 motivating this paper in the first place, the quotient categories retain essential information about dependence of the path/trace spaces on their end points in a compressed way.

6.2 Future work: relations to other constructions

As the motivating example (Sect. 1.2) shows, previously studied component categories (Fajstrup et al. 2004; Goubault and Haucourt 2007; Fajstrup et al. 2016) do not deliver categories with a countable number of objects, even when the directed space has the nice structure of a finite cubical complex. This paper advises a way to overcome this
default - and making the constructions of so-called “Natural homology” (Dubut et al. 2015) (and its precursor in Raussen (2007)) applicable in this more general setting. In contrast to other approaches, at least in principle, the definitions are suitable also in cases where the space admits directed loops. This option has only been investigated in detail only in a few concrete cases in Sect. 4.4; further development is desirable.

Ziemiański found a different way to overcome the shortcomings of previous work on components by defining and investigating stable components (Ziemiański 2019) that partition the directed space itself (instead of the space of reachable pairs). Path spaces between pairs of points within two components are, in general, not invariant up to -equivalence, but they become so after a stabilization process based on a number of well-motivated axioms. Path spaces between points in a given pair of components may vary but they stabilize when allowing large enough targets (resp. small enough sources). The resulting stable components are easier to determine than ours. It would be interesting to find out whether the components in this paper can be produced by partitioning reachable pairs of Ziemiański’s stable components into smaller pieces.

In a different direction, it is a challenge to develop a directed version of Michael Farber’s topological complexity (Farber 2008). The definitions can easily be modified by requiring directed paths, but one needs a better understanding of the end point map \( e : \vec{P}(X) \to X^2 \) and its partial sections. In the directed case, this map is, in general far from being a fibration, and the (Schwarz genus) methods from the classical theory are not available. First steps have been taken in Goubault et al. (2019); relations to methods from this paper might be helpful in future developments.

6.3 Future work: functoriality. Towards directed homotopy equivalences?

This section is only a first sketch.

A d-map \( F : X \to Y \) between two d-spaces does not give rise to any relation between the spaces of endo-d-maps \( \vec{C}(X, X) \) and \( \vec{C}(Y, Y) \); cf Sect. 2.1.4 for the notation. Instead, one needs a pair \( F : X \to Y \) and \( G : Y \to X \) of d-maps giving rise to the maps \( (G, F)_\# : \vec{C}(X, X) \to \vec{C}(X, X), \ f \mapsto F \circ f \circ G \) and \( (F, G)_\# : \vec{C}(Y, Y) \to \vec{C}(Y, Y), \ g \mapsto G \circ g \circ F \). We need further properties allowing us to relate the “homotopy dynamics” on the two d-spaces:

**Definition 8** A pair of d-maps \( F : X \to Y, \ G : Y \to X \) is called an \( \alpha\vec{F}\)-equivalence if there exist \( \alpha\vec{F} \) psp homotopy flows \( \mathcal{H}_1 : X \times I \to X \) connecting \( id_X \) with \( G \circ F \) and \( \mathcal{H}_2 : Y \times I \to Y \) connecting \( id_Y \) with \( F \circ G \).

In particular, for \( \vec{F} = \vec{F}_\infty \), the map \( F \) is an ordinary weak homotopy equivalence.

**Lemma 13** An \( \alpha\vec{F} \)-equivalence \( (F, G) \) induces \( \vec{F} \)-equivalences \( \vec{T}(G \circ F) : \vec{T}(X)^{X_{x_1}}_{G \circ F_{x_1}} \to \vec{T}(X)^{X_{x_1}}_{X_{x_1}}, \vec{T}(F \circ G) : \vec{T}(Y)^{Y_{y_1}}_{y_1} \to \vec{T}(Y)^{Y_{y_1}}_{F \circ G_{y_1}}, \vec{T}(F) : \vec{T}(X)^{X_{x_1}}_{x_1} \to \vec{T}(Y)^{X_{x_1}}_{F_{x_1}} \) and \( \vec{T}(G) : \vec{T}(Y)^{Y_{y_1}}_{y_1} \to \vec{T}(X)^{Y_{y_1}}_{G_{y_1}}, \ x_i \in X, \ y_i \in Y \).

**Proof** The first two properties follow from the definitions. For the last claims, apply the 2-out-of-6 property for (our) \( \vec{F} \)-equivalences. \( \square \)
It is tempting to call a d-map $F : X \to Y$ satisfying the requirements in Definition 8 a directed $\alpha \mathcal{F}$ equivalence; and for $\mathcal{F} = \mathcal{F}_\infty$—the (weak) homotopy equivalences—a directed (weak) $\alpha$ homotopy equivalence. But this definition is still not quite satisfactory. It is not clear that this notion

– satisfies a 2-out-of-3-properties
– leaves directed topological complexity (Goubault et al. 2019) invariant, and
– that it behaves well with respect to components.

The follow-up paper (Raussen 2019) responds to these challenges with an adjustment of Definition 8 as point of departure.
