(Received June 19, 2007)

Summary The aim of this study was to investigate the effect of the changes of taurine levels in the hearts of old rats on endogenous malondialdehyde (MDA) and diene conjugate (DC) levels and ascorbic acid (AA)- and NADPH-induced lipid peroxidation as well as non-enzymatic (glutathione, vitamin E and vitamin C) and enzymatic antioxidants (superoxide dismutase, glutathione peroxidase and glutathione transferase). Two groups of old (22 mo) rats were treated with β-alanine (3%, w/v; in drinking water), a taurine depleting agent, or taurine (2% w/v; in drinking water) for 6 wk. Significant decreases were observed in taurine contents of hearts in old rats as compared to young (5 mo) rats. We found that MDA and DC levels and AA- and NADPH-induced lipid peroxidation increased, but non-enzymatic and enzymatic antioxidants did not alter in heart homogenates of aged rats. β-Alanine administration resulted in significant decreases in heart taurine levels of old rats. This treatment did not cause further increases in MDA or DC levels or changes in antioxidants. However, AA- and NADPH-induced lipid peroxidation was higher than that of old rats. Taurine treatment caused significant increases in heart taurine levels of old rats. This treatment was found to decrease endogenous MDA and DC levels without affecting the antioxidant system in the heart homogenates of aged rats. AA- and NADPH-induced lipid peroxidation was also reduced in old rats when given taurine, although not statistically significantly. Our results indicate that the changes in heart taurine levels may influence the susceptibility of heart tissue to lipid peroxidation in aged rats and that taurine supplementation has protective effects on age-dependent oxidative stress in heart tissue.

Key Words taurine, aging, oxidative stress, heart, rat

Aging is associated with a decline in cardiovascular function and high cardiovascular mortality (1). Several reports have shown that oxidative stress plays an important role in the development of cardiac aging (2–4). Oxidative stress parameters such as malondialdehyde (MDA) (3, 5, 6), and 8-iso-prostaglandin F2α (3), protein carbonyl levels (7) and DNA damage (2–4) have been reported to be increased in the hearts of old rats, although some conflicting results are available (8, 9). Results related to non-enzymatic (2, 5, 7, 10) and enzymatic (6–9, 11) antioxidants in the heart of aged rats are conflicting.

Taurine (2-aminoethanesulfonic acid) is the major intracellular free β-amino acid, which is normally present in most mammalian tissues (12). It has various important biological and physiological roles such as antioxidation, osmoregulation, membrane stabilization, and regulation of intracellular calcium homeostasis (12). Taurine accounts for more than 50% of the total amino acid pool in the heart (13). Clinical and experimental studies have shown that taurine deficiency is associated with structural and functional disorders in the heart and that taurine treatment ameliorated cardiovascular disorders (1, 13, 14).

On the other hand, it has been reported that taurine levels decreased in plasma and tissues with aging (15–17). Since taurine is an important intracellular antioxidant, severe decreases in taurine levels of tissues may influence their antioxidant power and susceptibility to oxidative damage (15, 18, 19). Therefore, taurine deficiency in heart tissue may contribute to cardiac oxidative damage that occurs during the aging process (16, 17).

In this study, endogenous, ascorbic acid (AA)- and NADPH-induced lipid peroxidation and non-enzymatic and enzymatic antioxidants together with taurine levels were measured in heart homogenates of young and old rats. These measurements were also done in old rats treated with β-alanine, a taurine-depleting agent, or with taurine. Thus, we wanted to investigate how the changes in taurine levels affect endogenous and lipid peroxidation potential and antioxidant system in hearts of aged rats.

MATERIALS AND METHODS

Materials. Taurine, β-alanine and other chemicals were purchased from Sigma Chemical.
Animals and treatments. Young (5 mo) and old (22 mo) male Wistar rats were obtained from the Center for Experimental Medical Research Institute of Istanbul University. The animals were allowed free access to food and water and were kept in wire-bottomed stainless steel cages. The experimental procedure used in this study met the guidelines of the Animal Care and Use Committee of the University of Istanbul.

Old rats were divided into three subgroups as untreated, β-alanine- and taurine-treated old rats. β-Alanine was applied in drinking water (3%, w/v) for 6 wk to decrease taurine levels. Taurine (2%, w/v) was given also in drinking water for 6 wk. At the end of this period, young, old, β-alanine- and taurine-treated old rats were fasted overnight and the hearts of the rats were quickly removed and washed in 0.9% NaCl and kept in ice.

The determinations of taurine levels. Heart tissues were homogenized in ten volumes of 3% sulfosalisilic acid. After centrifugation, the supernatant was filtered through a 0.45 μm filter and taurine levels were determined with a Hewlett Packard amino acid analyzer (20).

The determinations of lipid peroxide levels. Tissues were homogenized in ice-cold 0.15 M KCl (10%, w/v). Lipid peroxidation was assessed by two different methods in the heart homogenates. First, the levels of malondialdehyde (MDA) were determined by the thiobarbituric acid test (21). The breakdown product of 1,1,3,3-tetraethoxypropane was used as a standard. Second, diene conjugate (DC) levels were measured in heart lipid extracts at 233 nm spectrophotometrically and calculated using a molar extinction coefficient of 2.52×10^4 M^−1 cm^−1 (22).

To determine induced lipid peroxide levels, two different media were prepared (23). The incubation mixture (1 mL) for the estimation of AA-induced lipid peroxidation contained 50 μM FeSO_4, 1 mM KH_2PO_4, 0.15 M Tris-HCl buffer (pH 7.4), 0.4 mM ascorbic acid and 0.1 mL tissue homogenate. For the NADPH-induced system, 50 μM FeCl_3 instead of FeSO_4, and 4 mM ADP were included and 0.4 mM NADPH was added instead of ascorbic acid. After incubation at 37°C in a shaking water bath for 30 min, the amount of MDA formed was estimated according to Buege and Aust (22).

The determinations of non-enzymatic and enzymatic antioxidants. Heart glutathione (GSH) levels were measured with 5,5-dithiobis-(2-nitrobenzoate) at 412 nm (24). Vitamin E and vitamin C levels were measured in heart homogenates by the method of Desai (25) and Omaye et al. (26), respectively. Superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) and glutathione transferase (GST) activities were determined in the postmitochondrial fraction of the heart, which was obtained by sequential centrifugation. In brief, heart homogenates were centrifuged at 600 × g for 10 min at 4°C to remove crude fractions. Then, supernatants were centrifuged at 10,000 × g for 20 min to obtain the postmitochondrial fraction. SOD activities were assayed by its ability to increase the effect of riboflavin-sensitized photooxidation of o-dianisidine (27). GSH-Px (28) and GST (29) activities were measured using cumene hydroperoxide and 1-chloro-2,4-dinitrobenzene as substrates, respectively. Protein levels were determined using bicinchoninic acid (30).

Statistical analysis. The results were expressed as mean±SD. Experimental groups were compared using the Kruskal-Wallis variance analysis test. Where significant effects were found, post-hoc analysis using the Mann-Whitney U test was performed, and p<0.05 was considered to be statistically significant.

RESULTS

a) Significant decreases (16.6%) were observed in taurine contents of the heart in old rats as compared to young rats (Fig. 1). Heart MDA (33.3%) and DC
Effects of β-Alanine and Taurine on Cardiac Oxidative Stress

(30.5%) levels and AA-(113.8%) and NADPH (66.0%)-induced lipid peroxidation increased (Figs. 2 and 3), but there were no changes in GSH, vitamin E or vitamin C levels, nor in SOD, GSH-Px or GST activities in heart homogenates of aged rats (Tables 1 and 2).

b) Heart taurine contents were found to be decreased (22.7%) in old rats following β-alanine treatment. MDA and DC levels as well as the antioxidant system did not further change in the heart of β-alanine-treated old rats. However, AA- and NADPH-induced lipid peroxidation was found to be increased (48.0% and 51.8%, respectively) in the heart homogenates of aged rats following β-alanine treatment.

c) Taurine levels were increased (32.4%) in heart homogenates in taurine-treated old rats. This treatment decreased MDA (24.2%) and DC (29.2%) levels without affecting non-enzymatic or enzymatic antioxidants. AA- (11.3%) and NADPH (14.4%)-induced lipid peroxidation was also reduced in old rats, although not statistically significantly.

**DISCUSSION**

Oxygen and nitrogen species generation (2, 7, 31) as well as oxidative stress parameters (2, 3, 6, 7, 32) were reported to be significantly increased in the hearts of old rats. In our study, MDA and DC levels were also found increased, although no alteration was observed in non-enzymatic or enzymatic antioxidant systems, which was in accordance with other studies (2, 7–9).

As it is known, AA-induced lipid peroxidation is a non-enzymatic reaction involving ferro iron and ascorbate, but enzymatic NADPH-induced lipid peroxidation is known to be mediated by the enzyme NADPH cytochrome c reductase and requires ferric iron chelated with ADP (23, 33). Both types of lipid peroxidation show peroxidation potential of tissues and are con-

trolled by several factors such as availability of substrates in the form of unsaturated fatty acids, the presence/absence of peroxidation inducers and inhibitors of free radical reactions (32). The heart is known to have a low total reactive antioxidant potential (34) and an ability to upregulate antioxidant defences and to repair accumulated peroxidative damage (7, 35). Therefore, the heart may have high susceptibility to prooxidant stimuli. However, unchanged (32) and decreased (11) AA-induced lipid peroxidation has been reported in heart homogenates of old rats. In the current study, we found that both AA- and NADPH-induced lipid peroxidation as well as endogenous lipid peroxidation increased in heart homogenates of old rats as compared to young rats.

On the other hand, some investigators have reported that taurine levels decreased in plasma and some tissues such as liver, brain and kidney with aging (15–17). However, no significant changes in taurine levels were detected in the heart or skeletal muscles of old rats (15). In the current study, we observed that taurine levels were decreased in heart homogenates of aged rats. If taurine plays a role in the normal antioxidant defence system, decreases in taurine levels in heart tissue may contribute to shift the balance toward a prooxidant environment.

β-Alanine is a well known antagonist of taurine transport which produces depletion of tissue taurine levels, since both amino acids share a common transport system, selective for β-amino acids (36, 37). Although some investigators have reported that taurine-deficient diets did not cause further decreases in taurine levels in tissues of old rats due to adaptive reactions (15, 16), there is not sufficient knowledge in the literature about the effect of β-alanine treatment on taurine levels in tissues of old rats.

In this study, we wanted to investigate whether β-alanine treatment affected taurine levels and the susceptibility of heart to lipid peroxidation in aged rats. In these rats, heart taurine levels were found further decreased and AA- and NADPH-induced lipid peroxidation further increased following β-alanine treatment, although there was no change in endogenous MDA or DC levels or antioxidant system parameters. Therefore, taurine depletion in the heart is observed to provoke peroxidation potential, but not endogenous lipid peroxidation probably due to the unchanged endogenous antioxidant system in old rats. According to this, the balance between prooxidant and antioxidant systems seems to be highly sensitive to taurine depletion in the heart tissue of old rats. On the contrary, in our recent study, although the administration of 3% β-alanine in the drinking water of young rats decreased taurine levels in the heart (15%), this treatment was found not to alter endogenous, AA- or NADPH-induced lipid peroxidation in heart homogenates (38).

On the other hand, high levels of MDA and DC in the hearts of old rats were found reduced with taurine treatment, without any change in antioxidant system parameters. Therefore, the supplemented amount of taurine appears to be sufficient to decrease high endogenous lipid peroxide levels in the heart of old rats. In addition, since lipid peroxidation induction in the heart tissue is lower in taurine-treated old rats than in β-alanine treated old rats, it can be considered that taurine may play a preventive role in the induction of lipid peroxidation arising due to prooxidant stimuli in aging.

In conclusion, our results indicate that the changes in taurine levels may influence the susceptibility of heart tissue to lipid peroxidation in aged rats and that taurine supplementation may have protective effects on age-dependent oxidative stress in heart tissue.
