(Dated: December 21, 2013)

Using the thermodynamic Bethe ansatz equations we study the quantum phase diagram, thermodynamics and criticality of one-dimensional spin-1 bosons with strongly repulsive density-density and antiferromagnetic spin-exchange interactions. We analytically derive a high precision equation of state from which the Tomonaga-Luttinger liquid physics and quantum critical behavior of the system are computed. We obtain explicit forms for the scaling functions near the critical points yielding the dynamical exponent $z = 2$ and correlation length exponent $\nu = 1/2$ for the quantum phase transitions driven by either the chemical potential or the magnetic field. Consequently, we further demonstrate that quantum criticality of the system can be mapped out from the finite temperature density and magnetization profiles of the 1D trapped gas. Our results provide the physical origin of quantum criticality in a 1D many-body system beyond the Tomonaga-Luttinger liquid description.

I. INTRODUCTION

The study of spinor Bose gases is an active area of research in the field of cold atoms \cite{1,2}. In an optical trap, the laser-atom interaction is determined by the induced electric dipole moment, thus the atoms are confined independently of their spin orientations. This has provided exciting opportunities of simulating quantum dynamics of spinor Bose-Einstein condensates in which the “vector” property of spinor atoms can be preserved. Several experimental groups have successfully demonstrated spinor BECs of \textsuperscript{23}Na \cite{3,4} and \textsuperscript{87}Rb \cite{5-7} atoms in optical traps. In particular, the exquisite tunability with ultracold atoms confined to low dimensions has provided unprecedented opportunities for testing the theory of one-dimensional (1D) exactly solvable many-body systems \cite{8-17}. These experimental developments have stimulated an extensive study of related exactly solvable models with $\delta$-function interactions, see recent reviews \cite{18,19}.

Quantum spinor gases with multi-spin states exhibit richer quantum effects than their single component counterparts. Spinor Bose gases with spin-independent short range interaction have a ferromagnetic ground state, i.e. the ground state is always fully polarized \cite{20,21}. In contrast to the two-component Fermi gases \cite{22}, the two-component spinor Bose gas with spin-independent $s$-wave scattering \cite{23,24} has a ferromagnetic ground state as long as the interaction is fully spin independent. However, 1D spinor Bose gas with short-range density-density and spin-exchange interactions \cite{25,26} can display a different ground state, i.e., either a ferromagnetic or an antiferromagnetic ground state solely depending on the spin-exchange interaction. In this context, the spin-1 spinor Bose gas with short-range delta-function interaction and antiferromagnetic spin-spin interaction is particularly interesting due to the existence of various phases of quantum liquids associated with the Bethe Ansatz (BA)
solutions \[26, 28, 30\]. At zero temperature, this model exhibits three phases in the chemical potential – magnetic field plane. These are (i) a spin-singlet phase of pairs of bosons with hyperfine states \(|F = 1, m_F = \pm 1\) or two \(|F = 1, m_F = 0\) bosons, (ii) a ferromagnetic phase of fully-polarized atoms in the hyperfine state \(|F = 1, m_F = 1\) and (iii) a mixed phase of spin-singlet pairs and unpaired single atoms.

Spinor Bose gases exhibit various phases of strongly correlated quantum criticality and universal scaling behaviour have been experimentally investigated in low-dimensional cold atom matter \[33, 34\]. In this framework, exactly solvable models of cold atoms, exhibiting quantum phase transitions, provide a rigorous way to treat quantum criticality in archetypical quantum many-body systems, such as the Gaudin-Yang Fermi gas \[38\], the Lieb-Liniger Bose gas \[39\] and a mixture of bosons and fermions \[40\].

Despite much work on the 1D spin-1 bosons with strongly repulsive density-density and antiferromagnetic spin-exchange interactions \[26, 28, 29\], there has been no study of the quantum criticality of the model by using the exact solution. Contrary to the impression one might have, exact solvability does not guarantee that physical quantities of interest can be actually calculated by the BA solutions. The thermodynamic Bethe ansatz (TBA) equations for this model \[26\] involve an infinite number of coupled nonlinear integral equations that impose a number of challenges to access the physics of the model.

In the present paper, building on the method proposed in the study of quantum criticality of the Gaudin-Yang Fermi gas \[38\] and the Lieb-Liniger Bose gas \[39\], we analytically study the quantum phase diagram, universal thermodynamics and criticality of spin-1 bosons with strongly repulsive density-density and antiferromagnetic spin-exchange interactions. We derive a high precision equation of state of the system in experimental accessible conditions, i.e., in the strong coupling regime and low temperatures. We also analytically derive the Tomonaga-Luttinger liquid (TLL) thermodynamics, quantum critical exponents and universal scaling functions near the critical points associated with quantum phase transitions driven by the chemical potential and magnetic field. These scaling forms for the thermodynamic properties across the phase boundaries illustrate the physical origin of quantum criticality in this system, where the singular part of the thermodynamic properties involves a sudden change of density of state for either pairs or unpaired single atoms.

The paper is organized as follows. In Sec II we present the model and its corresponding TBA equations. In Sec III we analytically determine the phase diagram of the model at zero temperature. In Sec IV we derive the equation of state and universal TLL thermodynamics in the physical regime, i.e., for strong coupling and low temperatures. In Sec V we investigate quantum critical behaviour driven by the chemical potential and magnetic field. The scaling functions near the critical points are obtained analytically. See VI is the conclusion.

II. THE MODEL

We consider \(N\) particles of mass \(m\) confined in 1D to a length \(L\) with \(\delta\)-interacting type density-density and spin-exchange interactions between two atoms. The Hamiltonian is given by \[1, 26\]

\[
H = -\sum_{i=1}^{N} \frac{\partial^2}{\partial x_i^2} + \sum_{i<j} \left[c_0 + c_2 S_i \cdot S_j \right] \delta(x_i - x_j) + E_z, \tag{1}
\]

where \(S_i\) is the spin-1 operator with \(z\)-component \((s = 1, 0, -1)\). The interaction parameters \(c_0 = (g_0 + 2g_2)/3\) and \(c_2 = (g_2 - g_0)/3\) where \(g_s = 4\pi\hbar^2 a_s/m\). Here \(m\) is the particle mass and \(a_S\) represents the \(s\)-wave scattering length in the total spin \(S = 0, 2\) channels. \(E_z = -HS^z\) stands for the Zeeman energy, where \(H\) is the external field and \(S^z\) the total spin in the \(z\)-component. In the above equation, we have set \(\hbar = 2m = 1\).

Using the BA hypothesis, Cao et al. \[26\] solved the model \(1\) with antiferromagnetic spin-exchange interaction for \(c = c_0 = c_2 > 0\). The energy eigenspectrum is given in terms of the quasi-momenta \(\{k_j\}\) of the particles through \(E = \sum_{j=1}^{N} k_j^2\), obeying the following set of coupled BA equations \[26\]

\[
\exp(ik_j L) = \prod_{\ell=1}^{N} k_j - k_\ell + 4c_1^j \prod_{\alpha=1}^{M} k_j - \Lambda_\alpha + 2c_1^j, \\
\prod_{\ell=1}^{N} \frac{\Lambda_\alpha - k_\ell + 2c_1^j}{\Lambda_\alpha - k_\ell - 2c_1^j} = -\prod_{\beta=1}^{M} \frac{\Lambda_\beta - k_\ell + 2c_1^j}{\Lambda_\beta - k_\ell - 2c_1^j}. \tag{2}
\]

Here \(c_1^j = c/4, j = 1, ..., N, \alpha = 1, ..., M\) and \(\{\Lambda_\alpha\}\) are the rapidities for the internal spin degrees of freedom. The quantum number \(M\) is a conserved quantity obeying the relation \(M = N - S^z\). In this model, the antiferromagnetic interaction leads to an effective attraction in the spin-singlet channel so that the singlet bosonic pairs comprise a spin singlet ground state. In the thermodynamic limit \(N, L \to \infty\), the sets of solutions \(\{k_j\}\) and \(\{\Lambda_\alpha\}\) of the BA equations \[2\] take a certain form, where the \(k_j\)'s and \(\Lambda_\alpha\)'s can form complex pairs \(k_j = \lambda_j + i\epsilon\) and \(\Lambda_\alpha = \lambda_j + i\epsilon\) where \(\lambda_j\) is real. Notice that each pair of \(k_j\)'s share the same real part as a corresponding pair of \(\Lambda_\alpha\)'s. The bound states are associated with a pair
of $|F = 1, m_F = \pm 1|$ bosons or two $|F = 1, m_F = 0|$ bosons. In addition to that, we also have real $k_j$’s and $\Lambda$ strings of the form $\Lambda^{k,j}_n = \Lambda^{k,j}_n + i(n+1-2j)c^j$, $j = 1, \ldots, n$ describing spin wave bound states.

At finite temperatures, the physical states become degenerate. The equilibrium state can be obtained by the condition of minimizing the Gibbs free energy $G = E + E_Z - \mu N - TS$, where $\mu$ is the chemical potential and $S$ the entropy, see Yang and Yang’s grand canonical description [41] of the BA equations for the integrable Bose gas. The Zeeman energy $E_Z = -HS_z$ and entropy $S$ are given in terms of the densities of charge bound states and spin-strings described above which are subject to the BA equations [2]. Minimizing the Gibbs free energy leads to a set of coupled non-linear integral equations, i.e., the TBA equations (see [29] for details)

$$
\varepsilon_1(k) = k^2 - \mu - H - T[a_4 \ast \ln(1 + e^{-\varepsilon_1(k)})] + T[a_1 - a_5] \ast \ln(1 + e^{-\varepsilon_1(k)})
\varepsilon_2(k) = 2(k^2 - c^2 - \mu) + T[a_1 - a_5] \ast \ln(1 + e^{-\varepsilon_1(k)}) - H[a_2 - a_4 - a_6] \ast \ln(1 + e^{-\varepsilon_2(k) + \frac{5}{2}}),
\phi_n(k) = n + T[a_{n+1} - a_{n+1}] \ast \ln(1 + e^{-\varepsilon_2(k)}) + T \sum_{n=1}^{\infty} T_{nm} \ast \ln(1 + e^{-\varepsilon_2(k)})).
\varepsilon_1(k) = k^2 - \mu - H + a_4 \ast \varepsilon_1(k) + [a_5 - a_1] \ast \varepsilon_2(k),
\varepsilon_2(k) = 2(k^2 - c^2 - \mu) + [a_5 - a_1] \ast \varepsilon_1(k) + [a_6 + a_4 - a_2] \ast \varepsilon_2(k)
$$

which are obtained from the TBA equations [3] in the limit $T \to 0$. The negative part of the dressed energies $\varepsilon_\alpha(k)$, $a = 1, 2$ for $k \leq Q_a$ corresponds to occupied states, while the positive part of $\varepsilon_\alpha$ corresponds to unoccupied states. The integration boundaries $Q_a$ characterize the “Fermi surfaces” defined by $\varepsilon_\alpha(Q_a) = 0$. In a canonical ensemble the bosonic pairs form a spin singlet ground state when the external field is less than a lower critical field.

III. PHASE DIAGRAM IN THE $\mu - H$ PLANE

The ground state properties and phase diagram at zero temperature can be determined by the dressed energy equations

$$
\varepsilon_1(k) = k^2 - \mu - H + a_4 \ast \varepsilon_1(k) + [a_5 - a_1] \ast \varepsilon_2(k),
\varepsilon_2(k) = 2(k^2 - c^2 - \mu) + [a_5 - a_1] \ast \varepsilon_1(k) + [a_6 + a_4 - a_2] \ast \varepsilon_2(k)
$$

$$
\tilde{\varepsilon}_1(x) = 8x^2 - \tilde{\mu}_{c1} - h + \frac{1}{\pi} \int_{-Q_1}^{Q_1} \frac{\tilde{\varepsilon}_1(x')}{1 + (x - x')^2} dx',
\tilde{Q}_1^2 = \frac{\tilde{\mu}_{c1}}{8} + \frac{h}{8\pi} - \frac{1}{8\pi} \int_{-Q_1}^{Q_1} \frac{\tilde{\varepsilon}_1(x')}{1 + (Q_1 - x')^2} dx',
$$

which give the critical field for the phase transition from a ferromagnetic phase of spin-aligned bosons into a mixed
phase of the pairs and unpaired bosons,

\[
\tilde{\mu}_{c3} = -\frac{1}{2} + \frac{2}{5\pi} \int_{-\tilde{Q}_1}^{\tilde{Q}_1} \frac{\tilde{\varepsilon}_1(x)}{1 + 16x^2/25} dx,
\]

\[
- \frac{2}{\pi} \int_{-\tilde{Q}_1}^{\tilde{Q}_1} \frac{\tilde{\varepsilon}_1(x)}{1 + 16x^2} dx.
\]  

(8)

where \(\tilde{Q}_1 = Q_1/c\) and \(\tilde{\varepsilon}_1(x)\) is given by (4).

The \(S-M\) phase boundary is determined by the conditions \(\varepsilon_1(k) \leq 0\) and \(\varepsilon_2(\pm Q_2) = 0\), from which we obtain the set of equations,

\[
\tilde{\varepsilon}_2(x) = 2 \left( 8x^2 - \frac{1}{2} - \tilde{\mu}_{c4} \right) + \frac{1}{\pi} \int_{-\tilde{Q}_2}^{\tilde{Q}_2} \frac{\tilde{\varepsilon}_2(x')}{{(x-x')^2}} dx' + \frac{2}{3\pi} \int_{-\tilde{Q}_2}^{\tilde{Q}_2} \frac{\tilde{\varepsilon}_2(x')}{{(x-x')^2}+9} dx' - \frac{2}{\pi} \int_{-\tilde{Q}_2}^{\tilde{Q}_2} \frac{\tilde{\varepsilon}_2(x')}{{1+4(x-x')^2}} dx'.
\]

\[
\tilde{Q}_2^2 = \frac{1}{16} + \frac{\tilde{\mu}_{c4}}{8} - \frac{1}{24\pi} \int_{-\tilde{Q}_2}^{\tilde{Q}_2} \frac{\tilde{\varepsilon}_2(x')}{1+4(Q_2-x')^2} dx' - \frac{1}{16\pi} \int_{-\tilde{Q}_2}^{\tilde{Q}_2} \frac{\tilde{\varepsilon}_2(x')}{1+(Q_2-x')^2} dx' + \frac{1}{8\pi} \int_{-\tilde{Q}_2}^{\tilde{Q}_2} \frac{\tilde{\varepsilon}_2(x')}{1+4(Q_2-x')^2} dx'.
\]  

(9)

that provide the critical fields for a phase transition from the spin-singlet phase of paired bosons into a mixed phase of pairs and unpaired bosons,

\[
\tilde{\mu}_{c4} = -h + \frac{4}{5\pi} \int_{-\tilde{Q}_2}^{\tilde{Q}_2} \frac{\tilde{\varepsilon}_2(x)}{1+16x^2/25} dx - \frac{4}{\pi} \int_{-\tilde{Q}_2}^{\tilde{Q}_2} \frac{\tilde{\varepsilon}_2(x)}{1+16x^2} dx.
\]  

(10)

Here \(\tilde{Q}_2 = Q_2/c\) and \(\tilde{\varepsilon}_2(x)\) is given by (4).

In order to investigate quantum criticality of the system in the strong coupling regime, we need closed form expressions for the critical fields. By Taylor expansion of Eqs. (8) and (10), we obtain the critical field values

\[
\tilde{\mu}_{c3} = -\frac{1}{2} + \frac{8\sqrt{7}}{15\pi} \left( h - \frac{1}{2} \right)^2 + \frac{104}{75\pi^2} \left( h - \frac{1}{2} \right)^2
\]

\[
\tilde{\mu}_{c4} = -h + \frac{32\sqrt{3}}{15\pi} \left( \frac{1}{2} - h \right)^2 + \frac{2912}{225\pi^2} \left( \frac{1}{2} - h \right)^2
\]  

(11)

(12)

which are in good agreement with the numerical results obtained from (8) and (10) in the strong coupling regime. These asymptotic results (Eqs. (11) and (12)) can also be obtained by converting the critical fields obtained in the \(H-n\) plane [29] into the \(\mu-H\) plane, where the effective chemical potentials \(\mu_1 = \mu + H\), \(\mu_2 = \mu + \epsilon_b/2\) for unpaired and paired bosons are presented explicitly in [29].

In the next section we will derive analytical expressions for the equation of state and universal TLL thermodynamics in the physical regime where \(t = T/\epsilon_b \ll 1\), i.e., for the strong coupling and low temperature regimes.

IV. EQUATION OF STATE AND TLL THERMODYNAMICS

The thermodynamics and the high precision of the equation of state of a system are the key informations that can be used to map out quantum critical phenomena and to make comparisons between theory and experiment. Recently, the equation of state of a two-component ultra-cold Fermi gas has been measured [42, 43] using theoretical schemes [44]. Such experimental advances provide exciting opportunities to test universal TLL and quantum critical phenomena in low dimensional many-body systems.

A. Equation of state

The lack of analytic solutions of the TBA equations limits the ability to make physical predictions of the model at finite temperatures. In fact, the thermodynamic properties of the model at finite temperature are notoriously difficult to extract due to the presence of the bosonic nature and the spin-spin exchange interaction. Building on the method presented in [38] and considering the physical region (strong coupling \(|c| \gg 1\) and low temperatures), we find that spin fluctuations are strongly suppressed by a strong field, i.e., \(H \gg T\). Therefore we can analytically extract the spin wave bound state contributions to the unpaired dressed energy, see the third equation in [4]. Moreover, we notice that the convolution terms converge rapidly once \(\varepsilon_{1,2}(k) > 0\) in the TBA equations. Therefore, we are allowed to carry out a Taylor expansion with respect to \(c\) in the kernel functions \(a_n^{S,S}\) in the TBA equations at low temperatures. Then, integrating by parts, we may obtain the dressed energies in
terms of polylogarithm functions up to order $1/|c|^3$,
\[
\varepsilon_1(k) \approx \frac{\hbar^2 k^2}{2m} - \mu - H - \frac{2|c|p_1}{c^2 + k^2} + \frac{4|c|p_2}{c^2 + 16k^2} - \frac{20|c|p_2}{25c^2 + 16k^2} - \frac{T^2}{2\sqrt{\pi} |c|^3 \left( \frac{\hbar^2}{2m} \right)^{\frac{3}{2}}} \text{Li}_{\frac{3}{2}} \left( -\frac{4^9}{c^2} \right) + \frac{1984T^2}{125\sqrt{2\pi} |c|^3 \left( \frac{\hbar^2}{2m} \right)^{\frac{3}{2}}} \text{Li}_{\frac{3}{2}} \left( -\frac{4^9}{c^2} \right) - Te^{-\frac{4}{c^2}} \left[ \left( 1 - \frac{2k^2}{c^2} \right) I_0 \left( \frac{K}{4} \right) + \frac{2k^2}{c^2} I_1 \left( \frac{K}{4} \right) \right],
\]
\[
\varepsilon_2(k) \approx \frac{2\hbar^2 k^2}{2m} - \frac{\hbar^2 c^2}{2m} - 2\mu + \frac{8|c|p_1}{c^2 + 16k^2} - \frac{40|c|p_1}{25c^2 + 16k^2} + \frac{3968T^2}{125\sqrt{2\pi} |c|^3 \left( \frac{\hbar^2}{2m} \right)^{\frac{3}{2}}} \text{Li}_{\frac{3}{2}} \left( -\frac{4^9}{c^2} \right) + \frac{2|c|p_2}{c^2 + 4k^2} - \frac{|c|p_2}{c^2 + k^2} - \frac{6|c|p_2}{9c^2 + 4k^2} + \frac{181T^2}{108\sqrt{2\pi} |c|^3 \left( \frac{\hbar^2}{2m} \right)^{\frac{3}{2}}} \text{Li}_{\frac{3}{2}} \left( -\frac{4^9}{c^2} \right). \tag{14}
\]

Here $\text{Li}_s(z) = \sum_{k=-1}^{\infty} z^k/k^s$ is the polylogarithm function. The terms $\tilde{K} = 8p_1/T|c|$ and $\tilde{I}_n(z) = \sum_{\gamma=0}^{\infty} (z/2)^{n+2\gamma}$ are obtained from the so-called “string” or spin wave contributions.

Using the above dressed energies and integrating by parts, we may calculate the pressure (4) in a straightforward way, with result

\[
p_1 \approx -\frac{T^2}{4\pi \hbar^2} f_1 \left( \frac{2m}{c^2 + \hbar^2/2m} \right) \left[ 1 - \frac{p_1}{|c|^3} \frac{2m}{\hbar^2} + \frac{3968p_2}{125|c|^3} \frac{2m}{\hbar^2} \right], \tag{15}
\]
\[
p_2 \approx -\frac{T^2}{4\pi \hbar^2} f_2 \left( \frac{2m}{c^2 + \hbar^2/2m} \right) \left[ 1 + \frac{3968p_1}{125|c|^3} \frac{2m}{\hbar^2} + \frac{181p_2}{108|c|^3} \frac{2m}{\hbar^2} \right], \tag{16}
\]

where we have denoted $f_i = \text{Li}_s \left( -\frac{4^9}{c^2} \right)$ with $i = 1, 2$ and

\[
A_1 = \mu + H + \frac{2p_1}{|c|} - \frac{16p_2}{5|c|} + Te^{-\frac{4}{c^2}} e^{-\frac{4}{c^2}} I_0 \left( \frac{K}{4} \right) + \frac{T^2}{|c|^3 \left( \frac{\hbar^2}{2m} \right)^{\frac{3}{2}}} \left[ \frac{1}{2\sqrt{\pi}} f_1^2 - \frac{1984}{125\sqrt{2\pi}} f_2^2 \right]. \tag{17}
\]
\[
A_2 = \frac{\hbar^2 c^2}{2m} + 2\mu - \frac{32p_1}{5|c|} - \frac{p_2}{3|c|} - \frac{T^2}{|c|^3 \left( \frac{\hbar^2}{2m} \right)^{\frac{3}{2}}} \left[ \frac{3968}{125\sqrt{\pi}} f_1^2 + \frac{181}{108\sqrt{2\pi}} f_2^2 \right]. \tag{18}
\]

Thus an infinite number of TBA equations have been simplified to two coupled equations, making the thermodynamics of the model analytically accessible.

The above expressions for the pressures (15) and (16) provide the precise equation of state of the system from which universal TLL thermodynamics and scaling functions near critical points can be further derived analytically. We present a high precision equation of state in the later discussions of the singularities of thermodynamic properties near the quantum critical point as the temperature tends to zero. To evaluate physical properties we substitute Eqs. (17) and (18) into Eq. (15) and (16). This provides two coupled equations for $p_1$ and $p_2$, which can be solved by iteration. We discuss the quantum criticality of the system using these pressures in the next Section.

### B. Universal TLL thermodynamics

In general, the free energy of a 1D many-body system at low temperatures can be naturally attributed to low-lying excitations near the Fermi points. From calculations of the finite temperature corrections to the free energy, one can extract universal TLL thermodynamics. This low energy physics can also be obtained from conformal field theory (CFT). Here we further develop an efficient way to obtain the universal TLL thermodynamics in the mixed phase of the pairs and unpaired bosons from the TBA equations (3). For temperatures $T \ll 1$ and the strong coupling regime $|c| \gg 1$, the gapless phase is in the region $H \sim c^2 \gg T$. Therefore, we can ignore the spin wave bound state contributions in this phase. The first few terms coming from an asymptotic expansion in the TBA equations (3) are given in terms of $1/|c|$: correc-
From Eq. (4) we obtain the pressures for spin-aligned single bosons and spin-singlet pairs

\[ p_1 = \left( \frac{\hbar^2}{2m} \right)^{-1/2} \frac{1}{\pi} \int_0^\infty \frac{\sqrt{2}}{1 + e^{(\varepsilon_1 - A_1^0)/T}} \, \, d\varepsilon_1, \tag{21} \]

\[ p_2 = \left( \frac{\hbar^2}{2m} \right)^{-1/2} \frac{\sqrt{2}}{\pi} \int_0^\infty \frac{\sqrt{2}}{1 + e^{(\varepsilon_2 - A_2^0)/T}} \, \, d\varepsilon_2, \tag{22} \]

where

\[ A_1^0 \approx \mu + H + \frac{2p_1}{|c|} \frac{16p_2}{5|c|}, \tag{23} \]

\[ A_2^0 \approx 2\mu + \frac{\hbar^2 c^2}{2m} - \frac{32p_1}{5|c|} - \frac{p_2}{3|c|}. \tag{24} \]

The integrals in (21) and (22) can be calculated explicitly via the Sommerfeld expansion. We assume that there are two “Fermi seas”, i.e., a Fermi sea of bound pairs with an effective chemical potential \( A_2^0 \) and a Fermi sea of unpaired bosons with an effective chemical potential \( A_1^0 \). From equations (19-24) and the relations \( n_1 = \frac{\partial f}{\partial \mu} \), \( n = n_1 + 2n_2 = \frac{\partial f}{\partial \mu} \), by a cumbersome iteration we can obtain closed forms for the pressures

\[ p_1 = \frac{2\pi^2 n_1^3}{3} \left( 1 - \frac{6n_1}{|c|} + \frac{96n_2}{5|c|} \right) + \frac{T^2}{6n_1} \left( 1 + \frac{2n_1}{|c|} + \frac{32n_2}{5|c|} \right), \tag{25} \]

\[ p_2 = \frac{\pi^2 n_2^3}{3} \left( 1 + \frac{48n_1}{5|c|} + \frac{n_2}{|c|} \right) + \frac{T^2}{3n_2} \left( 1 - \frac{16n_1}{5|c|} - \frac{n_2}{3|c|} \right). \tag{26} \]

The Helmholtz free energy per unit length is given by \( f = n\mu - p \). After a lengthy iteration, we obtain a universal leading temperature corrections to the free energy of the form

\[ f = f_0 - \frac{\pi T^2}{6} \left( \frac{1}{v_1} + \frac{1}{v_2} \right), \tag{27} \]

with \( f_0 \) the ground state already obtained in (24). Here

\[ v_1 = 2\pi n_1 \left( 1 + \frac{2(32n_2 - 10n_1)}{5|c|} \right) \tag{28} \]

and

\[ v_2 = \pi n_2 \left( 1 + \frac{2(48n_1 + 5n_2)}{15|c|} \right) \tag{29} \]

are the charge velocities for unpaired and paired bosons. The entropy per unit length is given by \( s = \frac{\partial f}{\partial T} \) where

\[ s = \frac{\pi T}{3} \left( \frac{1}{v_1} + \frac{1}{v_2} \right). \tag{30} \]

We observe that in this gapless phase, spin wave bound state fluctuations are suppressed due to a strong external field. The suppression of spin fluctuations leads to a
universality class of a two-component TLL in the mixed phase of pairs and unpaired bosons, which we denote by $T_{LM}$. At low temperatures, the spin singlet phase persists as a single component TLL (denoted by $T_{LLS}$) below a crossover temperature. The fully polarised singlet phase of pairs and unpaired bosons, which we denote persists as a single component TLL (denoted by $T_{LLP}$) below another crossover temperature. However, the TLL is not appropriate to describe quantum criticality, since it does not include proper thermal fluctuations for the quantum critical regime. In general the TLL persists below the crossover temperature at which the relation of the linear temperature-dependent entropy (or specific heat) breaks down.

In Figure 2 we present the entropy as a function of the temperature using these two different approaches – the polylogarithm function result \[ (31) \] and the Sommerfeld expansion \[ (30) \]. The crossover temperature $t^*$ determines the boundaries between the TLL regime and the quantum critical regime, see the contour plots of entropy in the $t - \mu$ plane for two different values of the external field in Figure 3. The crossover boundaries are established by the points at which the TLL entropy \[ (30) \] breaks down, i.e., the entropy is no longer linear temperature-dependent. At finite temperatures, the system exhibits the characteristic V-shaped behaviour of quantum criticality.

V. QUANTUM CRITICALITY

Quantum criticality describes the critical behavior near a quantum phase transition, i.e., it describes collective behavior of a large number of interacting particles at temperatures sufficiently low, such that quantum mechanics plays a crucial role in determining the distinguishing characteristics. \[ (31) \]. The quantum phase transition occurs at absolute zero temperature as the parameters of the system are varied. In the critical regime, a universal and scale-invariant description of the system is expected through the power-law scaling of thermodynamic properties. From the phase diagram of spin-1 bosons, see Figure 1 we observe that the quantum phase transition occurs as the driving parameters $\tilde{\mu}$ and $\tilde{h}$ cross the phase boundaries at zero temperature. Although there is no true finite temperature quantum phase transition in a 1D model, quantum criticality of a 1D many-body system is associated with a universal crossover $T^*$ that separates the excitation spectrum from relativistic to non-relativistic dispersion \[ (46, 47) \]. In the present spin-1 model of bosons, we can interpret the spin singlet phase as a TG gas of hard-core bosons with mass $2m$ and the spin-aligned ferromagnetic phase as a TG gas of single atoms with mass $m$. The mixed phase of two coupled TG gases is made of particles with mass $m$ and $2m$.

A. Criticality driven by a chemical potential

Quantum critical behaviour is uniquely characterized by the critical exponents depending only on the dimensionality and the symmetry of the excitation spectrum. This is reflected by singularities in the thermodynamic quantities, such as density $n$, compressibility $\kappa = \partial n / \partial \mu$ and magnetization $M$. They can be obtained from the derivatives of the pressure $p$ with respect to $\mu$ and $H$. In order to identify universal scaling of the thermodynamic properties in the quantum critical regime, we will only take into account the first few terms in the equation of state \[ (15) \] and \[ (16) \]. To this end, the total pressure is simplified as

$$\tilde{p} = -\frac{t^2}{2\sqrt{2\pi}} \left( \frac{1}{2} f_1^1 + \frac{1}{\sqrt{2}} f_2^1 \right),$$

(31)

where we have defined a dimensionless pressure $\tilde{p} = p/|c|e_0$ with the potentials

$$\tilde{A}_1 = \tilde{\mu} + \tilde{h} + 2\tilde{\mu}_1 - \frac{16\tilde{\rho}_2}{5},$$

(32)

$$\tilde{A}_2 = 1 + 2\tilde{\mu} - \frac{32\tilde{\rho}_2}{5} - \frac{\tilde{p}_2}{3},$$

(33)

and we have denoted the function $f_s^i = \tilde{L}_i \left( -\frac{\Lambda}{\tilde{\mu}} \right)$.

By iterating equations \[ (31) \], \[ (32) \] and \[ (33) \], we obtain the dimensionless density $\tilde{n} = n/|c|$, where

$$\tilde{n} = -\frac{\sqrt{7}}{2\sqrt{2\pi}} \left( \frac{1}{2} f_1^1 \Delta_1 + \sqrt{2} f_1^2 \Delta_2 \right),$$

(34)

with

$$\Delta_1 = 1 - \frac{t^{1/2}}{2\sqrt{2\pi}} f_1^1 + \frac{t}{8\pi} \left( f_1^1 \right)^2 + \frac{8t^{1/2}}{5\sqrt{2\pi}} f_1^2 + \frac{2t}{15\pi} \left( f_1^2 \right)^2 + \frac{12t}{25\pi \sqrt{2}} f_1^2 f_2^1,$$

$$\Delta_2 = 1 + \frac{4t^{1/2}}{5\sqrt{2\pi}} f_1^1 - \frac{t}{3\pi} \left( f_1^1 \right)^2 + \frac{t^{1/2}}{12\sqrt{2\pi}} f_1^2 + \frac{t}{144\pi} \left( f_1^2 \right)^2 + \frac{101t^{1/2}}{75\pi \sqrt{2}} f_1^2 f_2^1.$$

The total density \[ (31) \] depends on the density of single atoms and the density of paired atoms. Furthermore, using the standard thermodynamic relations, we obtain the magnetization $\tilde{M} = M/|c|$, 

$$\tilde{M} = -\frac{\sqrt{7}}{2\sqrt{2\pi}} \left\{ \frac{1}{2} f_1^1 \left( 1 - \frac{t^{1/2}}{2\sqrt{2\pi}} f_1^1 + \frac{t}{8\pi} \left( f_1^1 \right)^2 \right) + \frac{32t}{25\pi \sqrt{2}} f_1^2 f_1^2 \right\}$$

$$+ \sqrt{2} f_1^2 \left( \frac{4t^{1/2}}{5\sqrt{2\pi}} f_1^2 + \frac{t}{15\pi \sqrt{2}} f_1^2 f_1^2 \right) - \frac{t}{5\pi} \left( f_1^1 \right)^2 + \frac{t}{15\pi \sqrt{2}} f_1^2 f_1^2 \right\}$$

(35)
and the susceptibility $\tilde{\chi} \equiv \chi \epsilon_b / |c|$, 

$$
\tilde{\chi} = -\frac{1}{2\sqrt{2\pi f_1}} \left\{ \frac{1}{2} f_1^{-1/2} \left[ \frac{1}{2} f_1^{-1/2} \left( 1 - \frac{3t^{1/2}}{2\sqrt{2\pi f_1}} + \frac{3t}{4\pi} \left( f_1^{1/2} \right)^2 \right) + \frac{8t^{1/2}}{5\sqrt{2}} f_1^{-1/2} \left( f_1^{1/2} \right)^2 + \frac{2t}{15\pi} \left( f_1^{1/2} \right)^2 + \frac{36t}{25\pi\sqrt{2}} f_1^{-1/2} f_1^{1/2} \right] \right\}.
$$

(36)

By a lengthy calculation, the compressibility $\tilde{\kappa} \equiv \kappa \epsilon_b / |c|$ is given by 

$$
\tilde{\kappa} = -\frac{1}{2\sqrt{2\pi f_1}} \left\{ \frac{1}{2} f_1^{-1/2} \left[ (\Delta_1)^2 - \frac{t^{1/2}}{2\sqrt{2\pi f_1}} \left( 1 - \frac{3t^{1/2}}{2\sqrt{2\pi f_1}} + \frac{2t^{1/2}}{5\sqrt{2}} f_1^{-1/2} \right) \right] \right\}.
$$

(37)

These thermodynamic properties pave a way to extract universal scaling functions in the vicinity of the critical points $\tilde{\mu}_c$. Following the procedure discussed in Ref. 38, quantum criticality of these thermodynamic quantities can be obtained in the limit $T \to 0$ and $T > |\tilde{\mu} - \tilde{\mu}_c|$ across each of the phase boundaries, with the results

$$(V - F) \begin{cases} 
\tilde{n} \sim -\frac{2^{1/2}}{3\sqrt{2\pi}} \tilde{L}_i \left( -e^{\frac{\tilde{\mu} - \tilde{\mu}_c}{\tilde{\epsilon}} \tilde{t}} \right), \\
\tilde{M} \sim -\frac{2^{1/2}}{3\sqrt{2\pi}} \tilde{L}_i \left( -e^{\frac{2(\tilde{\mu} - \tilde{\mu}_c)}{\tilde{\epsilon}} \tilde{t}} \right) \sim 0,
\end{cases}
$$

(38)

$$(V - S) \begin{cases} 
\tilde{n} \sim -\frac{2^{1/2}}{3\sqrt{2\pi}} \tilde{L}_i \left( -e^{\frac{2(\tilde{\mu} - \tilde{\mu}_c)}{\tilde{\epsilon}} \tilde{t}} \right), \\
\tilde{M} \sim \frac{2^{1/2}}{5\sqrt{2\pi}} \tilde{L}_i \left( -e^{\frac{2(\tilde{\mu} - \tilde{\mu}_c)}{\tilde{\epsilon}} \tilde{t}} \right) \sim 0,
\end{cases}
$$

(39)

$$(F - M) \begin{cases} 
\tilde{n} \sim \tilde{n}_03 - \lambda_1 \sqrt{\tilde{L}_i} \left( -e^{\frac{2i(\tilde{\mu} - \tilde{\mu}_c)}{\tilde{\epsilon}} \tilde{t}} \right), \\
\tilde{M} \sim \tilde{M}_03 + \lambda_2 \sqrt{\tilde{L}_i} \left( -e^{\frac{2i(\tilde{\mu} - \tilde{\mu}_c)}{\tilde{\epsilon}} \tilde{t}} \right),
\end{cases}
$$

(40)

$$(S - M) \begin{cases} 
\tilde{n} \sim \tilde{n}_04 - \lambda_3 \sqrt{\tilde{L}_i} \left( -e^{\frac{2i(\tilde{\mu} - \tilde{\mu}_c)}{\tilde{\epsilon}} \tilde{t}} \right), \\
\tilde{M} \sim -\lambda_4 \sqrt{\tilde{L}_i} \left( -e^{\frac{2i(\tilde{\mu} - \tilde{\mu}_c)}{\tilde{\epsilon}} \tilde{t}} \right).
\end{cases}
$$

(41)

Here $\tilde{M}_03 = \tilde{n}_03$, $\tilde{n}_04$, $\lambda_i$, with $i = 1 \ldots 4$, $\rho$ and $\tilde{t}$ are constants, independent of $\tilde{\mu}$ and $t$. They are given explicitly by

$$
\tilde{n}_{03} = \frac{\sqrt{a}}{2\pi\sqrt{2}} \left( 1 + \frac{\sqrt{a}}{\pi\sqrt{2}} + \frac{a}{2\pi} \right),
$$

$$
\tilde{n}_{04} = \frac{\sqrt{b}}{\pi} \left( 1 - \frac{\sqrt{b}}{6\pi} + \frac{b}{36\pi^2} \right),
$$

$$
\lambda_1 = \frac{1}{2\sqrt{2\pi}} \left( 1 - \frac{16\sqrt{a}}{5\pi\sqrt{2} - 25\pi^2} \right),
$$

$$
\lambda_2 = \frac{4\sqrt{a}}{5\sqrt{2\pi}t^{1/2}} \left( 1 - \frac{3a}{5\pi^2} \right),
$$

$$
\lambda_3 = \frac{1}{4\sqrt{2\pi}} \left( 1 - \frac{3\sqrt{a}}{5\pi^2} + \frac{848b}{75\pi^2} \right),
$$

$$
\lambda_4 = \frac{1}{4\sqrt{2\pi}} \left( 1 - \frac{16\sqrt{b}}{5\pi^2} + \frac{8b}{15\pi^2} \right),
$$

(42)

with

$$
a = \left( h - \frac{1}{2} \right) \left( 1 + \frac{13\sqrt{2}}{15\pi} \sqrt{h - \frac{1}{2}} \right),
$$

$$
b = \left( \frac{1}{2} - h \right) \left( 1 + \frac{91\sqrt{2}}{45\pi} \left( \frac{1}{2} - h \right) \right).
$$

In the above equations $\tilde{n}_{03}$ and $\tilde{n}_{04}$ are the background densities near the critical points $\mu_3$ and $\mu_4$, respectively. At quantum criticality, the above densities can be cast into a universal scaling form (see Ref. 31, 32, 36), e.g.,

$$
n(\mu, T) = n_0 + T^{\frac{d}{2} + 1 - \frac{\Delta}{d}} G \left( \frac{\mu - \mu_c}{T^{\frac{\Delta}{d}}} \right).
$$

(43)

Here the dimensionality $d = 1$ and the scaling function $G(x) = \lambda \tilde{L}_i(x)$ with a constant $\lambda$. Consequently the dynamical critical exponent $z = 2$ and the correlation length exponent $\nu = 1/2$ can be read off from the universal scaling form (43). We observe that the spin-1 Bose gas belongs to the same universality class as spin-1/2 attractive fermions (38) due to the hard-core nature of the two coupled Tonks-Girardeau gases.

In Figures 4 and 5 we plot the “scaled density” $T^{-\left(\frac{d}{2} + \frac{1}{2} - \frac{\Delta}{d}\right)} n(\mu, T) - n_0$ versus $\tilde{\mu}$ for different values of the temperature near the critical points $\mu_{c1}, \mu_{c2}, \mu_{c3}$ and $\mu_{c4}$. We observe that after an appropriate subtraction of the background density all curves at different temperatures intersect at the critical points, which is the hallmark of criticality. In the regime of low polarization, i.e., $P < P_c$, the true phase transitions from the vacuum into the spin-singlet paired phase and from the pure paired phase into the mixture of spin-singlet pairs and spin-aligned bosons occur as the chemical potential passes the lower critical point $\tilde{\mu}_{c1}$ (63) and the upper critical point $\tilde{\mu}_{c4}$ (122), respectively, see Figure 4.

For large polarization, i.e., $P > P_c$, the phase transitions from vacuum into the ferromagnetic spin-aligned boson phase and from the spin-aligned boson phase into
the mixture of spin-singlet pairs and spin-aligned bosons occur as the chemical potential varies across the lower critical point \( \mu_{c1} \) (6) and the upper critical point \( \mu_{c3} \) (11), respectively, see Figure 4. The universal scaling behaviour and the zero temperature phase diagram can be identified from the finite temperature density profiles of the trapped gas where the local chemical potentials are replaced by the harmonic trapping potential.

Furthermore, we mention that similar calculations of the scaling function can be constructed for the compressibility across all phase boundaries,

\[
\begin{align*}
(V - F) & \quad \tilde{\kappa} \approx -\frac{1}{4\sqrt{2\pi}t} \text{Li}_{-\frac{1}{2}} \left(-e^{\frac{\mu - \mu_{c1}}{t}}\right) , \\
(V - S) & \quad \tilde{\kappa} \approx -\frac{1}{\sqrt{\pi}t} \text{Li}_{-\frac{3}{2}} \left(-e^{2\frac{\mu - \mu_{c1}}{t}}\right) , \\
(F - M) & \quad \tilde{\kappa} \approx \tilde{\kappa}_{03} - \frac{\lambda_5}{\sqrt{t}} \text{Li}_{-\frac{1}{2}} \left(-e^{\frac{\mu - \mu_{c3}}{t}}\right) , \\
(S - M) & \quad \tilde{\kappa} \approx \tilde{\kappa}_{04} - \frac{\lambda_6}{\sqrt{t}} \text{Li}_{-\frac{1}{2}} \left(-e^{\frac{\mu - \mu_{c3}}{t}}\right) .
\end{align*}
\]

(44)

Here \( \tilde{\kappa}_{03} \) and \( \tilde{\kappa}_{04} \) are the background compressibility in the vicinities of the critical points \( \mu_{c3} \) (Eq. (11)) and \( \mu_{c4} \) (Eq. (12)), whereas \( \lambda_5 \) and \( \lambda_6 \) are temperature-independent.
constants

\[
\kappa_{03} = \frac{1}{4\pi\sqrt{2a}} \left(1 + \frac{3\sqrt{a}}{\pi\sqrt{2}} + \frac{3a}{\pi^2}\right), \quad (45)
\]

\[
\kappa_{04} = \frac{1}{\pi\sqrt{b}} \left(1 - \frac{\sqrt{b}}{2\pi} + \frac{b}{6\pi^2}\right), \quad (46)
\]

\[
\lambda_5 = \frac{1}{\sqrt{\pi}} \left(1 - \frac{24\sqrt{a}}{5\pi\sqrt{2}} + \frac{36a}{25\pi^2}\right), \quad (47)
\]

\[
\lambda_6 = \frac{1}{4\sqrt{2\pi}} \left(1 - \frac{36\sqrt{b}}{5\pi} + \frac{44b}{25\pi^2}\right). \quad (48)
\]

Again, the critical exponents \(z = 2\) and \(\nu = 1/2\) can be read off the universal scaling function \(F(x) = \lambda Li_{-\frac{x}{\lambda}}\) in the universal form

\[
\kappa(\mu, T) = \kappa_0 + T^{\frac{4}{5} + 1 - \frac{z}{2}} F\left(\frac{\mu - \mu_c}{T^{\frac{4}{5}}\pi}\right). \quad (49)
\]

B. Criticality driven by a magnetic field

The quantum phase transitions driven by a magnetic field are particularly interesting. In the phase diagram Figure 11 for fixed chemical potential we can vary the external field \(H\) to pass the phase boundaries \((S - M)\) and \((M - F)\). At finite temperatures, the three zero temperature quantum phases, i.e., the phase of singlet pairs, ferromagnetic phase of spin-aligned atoms and the mixed phase of pairs and single atoms, become the relativistic TLL of bound pair (TLL\(_b\)), TLL of single atoms (TLL\(_F\)) and a two-component TLL (TLL\(_M\)) of paired and single atoms, respectively. We obtain the critical fields by converting the critical fields Eq. (12) and Eq. (13)

\[
h_{c1} = -\mu + \frac{32\sqrt{\pi}}{15\pi} \left(\mu + \frac{1}{2}\right)^{\frac{5}{2}} - \frac{32}{45\pi^2} \left(\mu + \frac{1}{2}\right)^2, \quad (50)
\]

\[
h_{c2} = -\mu + \frac{1}{2} \left(15\pi\right)^{\frac{5}{4}} \left(\mu + \frac{1}{2}\right)^{\frac{5}{2}} - \frac{5}{8} \left(\mu + \frac{1}{2}\right), \quad (51)
\]

These critical fields and the crossover temperatures can be observed in the contour plot of the entropy in the \(T - H\) plane, see Figure 6. The low energy TLL physics breaks down at the crossover temperature (dashed lines) where the dispersion of either bound pairs or unpaired single atoms becomes nonrelativistic. In particular, in the vicinity of the quantum critical points \(h_{c1}\) and \(h_{c2}\), the system exhibits two different quantum critical regimes. From equations (34), (35) and (37), we find the scaling function in the critical regime near the critical point (50)

\[
\begin{align*}
(S - M) & \quad \left\{ \begin{array}{l}
\tilde{n} \simeq \tilde{n}_{05} - \lambda_7 \sqrt{\pi} Li_{\frac{1}{2}} \left( -e^{-\frac{h-b/m}{h/b}} \right), \\
\tilde{M} \simeq -\lambda_8 \sqrt{\pi} Li_{\frac{1}{2}} \left( -e^{-\frac{h-b/m}{h/b}} \right), \\
\tilde{\kappa} \simeq \tilde{\kappa}_{05} - \lambda_9 \sqrt{\pi} Li_{\frac{1}{2}} \left( -e^{-\frac{h-b/m}{h/b}} \right),
\end{array} \right.
\end{align*} \quad (52)
\]

\[
(F - M) \quad \left\{ \begin{array}{l}
\tilde{n} \simeq \tilde{n}_{06} - \lambda_{10} \sqrt{\pi} Li_{\frac{1}{2}} \left( -e^{-\alpha(h-b/m)} \right), \\
\tilde{M} \simeq -\lambda_{11} \sqrt{\pi} Li_{\frac{1}{2}} \left( -e^{-\alpha(h-b/m)} \right), \\
\tilde{\kappa} \simeq \tilde{\kappa}_{06} - \lambda_{12} \sqrt{\pi} Li_{\frac{1}{2}} \left( -e^{-\alpha(h-b/m)} \right),
\end{array} \right. \quad (53)
\]

where the constants are given by

\[
\tilde{n}_{05} = \frac{\sqrt{d}}{\pi} \left(1 - \frac{\sqrt{d}}{6\pi} + \frac{d}{36\pi^2}\right),
\]

\[
\tilde{n}_{06} = \frac{\sqrt{d}}{\pi} \left(1 - \frac{\sqrt{d}}{2\pi} + \frac{d}{6\pi^2}\right),
\]

\[
\lambda_7 = \frac{1}{4\sqrt{2\pi}} \left(1 - \frac{32\sqrt{d}}{5\pi} + \frac{84d}{75\pi^2}\right),
\]

\[
\lambda_8 = \frac{1}{4\sqrt{2\pi}} \left(1 - \frac{16\sqrt{d}}{5\pi} + \frac{8d}{15\pi^2}\right),
\]

\[
\lambda_9 = \frac{1}{4\sqrt{2\pi}} \left(1 - \frac{36\sqrt{d}}{5\pi} + \frac{44d}{25\pi^2}\right),
\]

with

\[
d = 2 \left(\tilde{\mu} + \frac{1}{2}\right) \left(1 - \frac{\sqrt{2}}{9\pi} \sqrt{\tilde{\mu} + \frac{1}{2}}\right),
\]

\[
e = \frac{1}{2} \left(\frac{15\pi}{4}\right)^{\frac{5}{4}} \left(\tilde{\mu} + \frac{1}{2}\right)^{\frac{5}{2}}.
\]

In the vicinity of the quantum critical points \(h_{c2}\), we obtain the scaling forms
densities near the critical points. We can obtain similar scaling behaviour for the appropriate subtraction of the background magnetization. Let us denote the critical exponent by $\nu$ and the correlation length exponent by $\lambda$. The density (or magnetization) driven by the chemical potential, i.e. the dynamical critical exponent $z = 2$ and the correlation length exponent $\lambda = 1/2$. The density (magnetization) at the critical point is $\tilde{\nu}_{06} = \tilde{n}_{06}$.

In this case, the background density $\tilde{M}_{06} = \tilde{\nu}_{06}$ is equal to the total density at the critical point. The density (magnetization) and compressibility can be recast into the universal scaling forms

$$M(h, T) = n_0 + T^{\frac{d}{2}+1-\frac{1}{z}} G \left( \frac{\alpha(h-h_c)}{T^{\frac{1}{z}}} \right),$$

$$\kappa(\mu, T) = \kappa_0 + T^{\frac{d}{2}+1-\frac{2}{z}} F \left( \frac{\alpha(\mu-\mu_c)}{T^{\frac{1}{z}}} \right),$$

with the same critical exponents as that for quantum criticality driven by the chemical potential, i.e. the dynamical critical exponent $z = 2$ and the correlation length exponent $\nu = 1/2$.

In Figure 7 we show the magnetization as a function of the external field for different temperatures for a fixed chemical potential. All curves intersect at the critical point $h_{c1}$ without background magnetization. However, these curves intersect at the upper critical point $h_{c2}$ with appropriate subtraction of the background magnetization. We can obtain similar scaling behaviour for the densities near the critical points $h_{c1}$ and $h_{c2}$ like that presented in Figures 4 and 5. It turns out that magnetization can be used to map out the bulk phase diagram through the 1D trapped gas at finite temperatures.

**VI. CONCLUSION**

Using the TBA equations, we have studied the quantum phase diagram, thermodynamics and quantum critical behaviour of one-dimensional spin-1 bosons with strongly repulsive density-density and antiferromagnetic spin-exchange interactions. We have determined with high precision the equation of state from which the TLL thermodynamics, universal scaling functions and critical exponents have been obtained. The universality class of quantum criticality has also been discussed.
paired single atoms. The phase diagram, the TLL thermodynamics and critical properties of the bulk system can be mapped out from the density and magnetization profiles of the trapped spinor gas at finite temperatures. Our results open the way to further study such universal features of 1D many-body physics in experiments with ultracold atoms.
