Review Article

Psychosocial and Mental Health Issues of the Migrants Amidst COVID-19 Pandemic in India: A Narrative Review

Gurvinder Pal Singh

ABSTRACT

Background: The objective of this review was to identify and synthesize the findings of the existing literature that highlighted the psychosocial and mental health issues of the migrants during the COVID-19 pandemic in India.

Materials and Methods: An exploration of the PubMed, Google Scholar, Web of Science, ScienceDirect, Google search, and some other manual searches was undertaken so that no relevant study was missed. A search on Indian scientific literature and cross-references retrieved was also conducted to get further information. The period of the search has been one year from March 1, 2020, to March 31, 2021. The database was searched with the terms “migrants,” “migrant workers,” “COVID-19 pandemic,” “lockdown,” “migrant population,” “mental health issues,” “psychosocial issues” to retrieve the published literature.

Results: Initially, 48 research articles were retrieved and 10 of them were excluded as they had no sufficient information about mental and psychosocial challenges faced by the migrants. In the remaining 38 articles, 9 articles were original research work (n = 9) published from India related to the impact of COVID-19 on migrants. The second category consisted of editorials or commentary or letters to the editor or policy paper on psychosocial and mental health aspects of migrants during the COVID-19 pandemic (n = 17). The third category was 11 articles on perspectives or opinions or viewpoints (n = 11) related to various psychosocial and mental health issues among migrants in India during the COVID-19 pandemic. Predominantly psychosocial issues found among migrants were living conditions, basic needs, family concerns, and joblessness. The mental health issues found among migrants during the COVID-19 pandemic included psychological distress, depressive disorders, anxiety disorders, substance use disorders.

Conclusion: Existing literature from India has shown that the COVID-19 pandemic severely impacted the psychosocial and mental health status of the migrants in India. This review suggests the need for more research work from the affected states of India and the development of psychosocial and mental health intervention strategies to minimize the impact of the COVID-19 pandemic on migrants.

Keywords: COVID-19 pandemic, India, literature reviews, mental health issues, migrants, psychosocial issues

The COVID-19 pandemic has highlighted the vulnerability of the migrants in India as they were found at a higher risk than the local population for active disease. Lockdown, announced in the country on the evening of March 24, 2020, struck a blow on their mental state, and they faced psychosocial and mental health crises during the pandemic. This pandemic has caused an increase in psychological stress, severe psychiatric disorders, substance dependence, and suicidal tendencies among the migrants. The pandemic has uncovered a mental health crisis for the migrants, which was described with a novel phrase, “pandemonium of the pandemic.”

Psychological support was provided to them in many states, as their mental health issues became prominent during the first wave of the pandemic. Subsequently, alleviating the harmful effects...
Singh

of COVID-19 on the mental health of migrants has become a priority for public health authorities in India. Lack of work, starvation, insanitary conditions, lack of housing and transport facilities, insecurity, unemployment, lack of social protection, and the uncertainty in life were the various crises they faced. Literature has originated from some of the affected states of India, while their experiences living in other parts of India have remained an unresearched area. Thus, there is a need for further research and understanding of this health problem in the affected states of India. The objective of the review was to determine the psychosocial and mental health issues among the migrants in India in the literature published during the COVID-19 pandemic.

Methods

Search Strategy

An exploration of PubMed, Google Scholar, Web of Science, ScienceDirect, and Google was done. Some other manual searches too were undertaken to cover maximum relevant studies. A search on Indian scientific literature and cross-references retrieved was also conducted to get further information. An initial search exercise revealed that the migrant research literature in India was too heterogeneous to permit a systematic review. The literature retrieved was sufficient only for conducting a narrative review. The database searches were conducted with the terms “migrants,” “migrant workers,” “COVID-19 pandemic,” “lockdown,” “migrant population,” “mental health issues,” and “psychosocial issues” to retrieve the research published literature. The period of the search was from March 1, 2020, to March 31, 2021. The review focused on this period because it was during this period that the migrants faced multiple health challenges during the first wave of the pandemic.

Study Selection and Data Extraction

Initially, 48 research articles were retrieved. Ten were excluded as they had no sufficient information about mental and psychosocial issues faced by the migrants. A careful review of the remaining 38 articles identified research literature relevant to the objective of this review. Most of the research work was conducted online or through telephone.

The literature from various resources were summarized and categorized into three subtypes. The first category was of nine articles that were original research work published from India. The second category consisted of editorials, reviews, commentaries, letters to the editors, and policy papers (n = 17). The remaining 11 articles were perspectives, opinions, or viewpoints (see Figure 1).

Results

Broadly, there were two themes (psychosocial and mental health issues) in the 38 selected articles. Only nine articles were original research work. They included seven cross-sectional studies and two qualitative studies, and an experiential report. Four studies were multicentric from various states and cities of India and were conducted with strong methodology and assessments. The findings pertaining to the migrants in the four multicentric studies have been highlighted in Table 1. The number of participants in various research studies ranged from 25 to 35,000.

The large population-based observational study of a sample of 35,000 was reported from the states of Bihar, Jharkhand, Uttar Pradesh, and Karnataka. The authors collected data from helpline records established to address the various psychosocial issues of the migrants. Eighty percent of migrants from these four states received no government aid. Similarly, in an online survey, the authors examined the impact of joblessness following the pandemic on income and remittances of 451 migrants in the northeast region. Some studies examined psychosocial and mental health issues of migrants staying in shelter homes established at various places by the Government of India.

Literature on Psychosocial Issues

Living conditions, basic needs, housing, transport facility, family concern, risk of infection, issues of children and women, poverty, future insecurity, and inadequate social support were the predominant psychosocial issues reported. The research work was from 13 states and one union territory, including...
A population-based large-scale study of 25,371 migrants reported that 40% of them faced food scarcity.25 Similar finding was also revealed in another study: 40% experienced psychosocial issues related to the lack of access to food, housing, and living conditions.14

Some studies discussed the mode of transport used by the migrants in reaching their native places.6,11 They reported that 51%–83% of the participants made the journey by bus and train and 6%–10% made the journey on foot.6,11 The majority of the migrants were psychologically distressed and showed a lack of resilience to the pandemic crisis.6,6 Another article explained that an understanding of migration and livelihood would be helpful in designing a mitigating strategy for the psychosocial impact of COVID-19. The authors emphasized that the migrants suffer from the dual burden of being poor and migrants.19 The migrants in informal sectors faced significant psychosocial issues and had to bear the difficulties of survival.14,10

In one cross-sectional study that highlighted joblessness issues, the migrants remained jobless for two months and failed to send remittances to their families.10 The psychosocial impact of joblessness was observed more in elderly migrants. In a multicentric study, the authors administered migration questionnaire to 551 participants staying in shelter homes. They found that the participants feared contracting COVID-19 and were uncertain about return to their native places.8 Twenty percent reported that they had no place to stay.8 Thirty-eight percent went home due to family pressure. The financial issues revealed were the need to support the family during harvesting season and better job opportunities back home. Twelve percent of the participants reported termination of the job by the employer.8,11

A population-based large-scale study of 25,371 migrants reported that 40% of them faced food scarcity.25 Similar finding was also revealed in another study: 40% experienced psychosocial issues related to the lack of access to food, housing, and living conditions.14

Some studies discussed the mode of transport used by the migrants in reaching their native places.6,11 They reported that 51%–83% of the participants made the journey by bus and train and 6%–10% made the journey on foot.6,11 The majority of the migrants were psychologically distressed and showed a lack of resilience to the pandemic crisis.6,6 Another article explained that an understanding of migration and livelihood would be helpful in designing a mitigating strategy for the psychosocial impact of COVID-19. The authors emphasized that the migrants suffer from the dual burden of being poor and migrants.19 The migrants in informal sectors faced significant psychosocial issues and had to bear the difficulties of survival.14,10

In a North Indian study, the prevalence of substance use was found to be higher among migrants than the general population.4 The prevalence of ever use for all the substances was 44%, ever use of alcohol was 16%, and the current use of alcohol was 11% among migrants. The authors reported the prevalence of ever use of cannabis was 4% and tobacco use were 36% in their study.4 Another study
revealed that the migrants had decreased self-esteem, poor socialization, and were facing multiple mental health issues. They were feeling helpless, suffering from anxiety, and fearing death. Fear of getting infection was reported by 16% of migrants. Twenty percent (20%) reported that they had felt low and gloomy, and 19% reported restlessness. Marked psychological distress, insomnia, deliberate self-harm, severe depressive symptoms were reported. At least one psychiatric diagnosis (depressive disorder) was found to be significantly higher among the migrants than the general population. Another study from North India, published as letter to the editor, reported that 73% of the migrants screened positive for depression. There have been some reports of severe anxiety, panic disorder, increased susceptibility to major depressive disorder with psychotic symptoms, and suicidal risk.

A population-based study of 353 migrants found mental stress and anxiety in 31% of the participants. In an experiential report from Karnataka,13 migrants were found to have a pre-existing psychiatric disorder, five were diagnosed with new-onset psychiatric disorders, and five were referred for further psychiatric care. The authors reported that the mental health team made available supported in the migrants’ camps and shelter homes, and brief psychosocial interventions helped in decreasing the distress of the migrants.

Some other articles published as editorials, commentaries, viewpoints, opinions, perspectives, or letters to the editor focused on the development of fear; anxiety, depressive, and other common mental disorders (CMDs); and related issues among the migrants. Regular assessment and early intervention of mental disorders were attempted, with positive outcomes. The mental health team support and brief psychosocial support helped in decreasing the distress of the migrants and their fear of threat to survival. The psychosocial services were provided to migrants by district mental health team at Chandigarh and Bengaluru. Regular assessment and early intervention of mental disorders were undertaken. Telepsychiatry services with a helpline for mental health issues was utilized by migrants.

In a large-scale international survey, migrant’s mental health issues were assessed in the context of COVID-19. The findings of this survey revealed that daily stressors of basic needs, medical needs, and social needs were found to have a significant association with the mental health issues of the migrants. The other findings of this global survey were that the perceived discrimination among migrants had a significant effect on their anxiety and depression. In the present review, many Indian researchers reported similar findings of the significance of basic needs, living conditions, and mental health issues among migrants. Similar to the present review, in a systematic review of mental health among migrants before COVID-19, Mucci et al. reported that migrants showed an increase in the incidence of psychiatric disorders due to loss of social status and separation from the families. The important emerging disorders were depressive disorders, anxiety disorders, alcohol or substance abuse, and poor sleep quality. Similar findings of psychiatric morbidity among migrants were found in the present review during COVID-19 even though the number of studies was small. Mucci et al. emphasized the role of promotion in the well-being of migrants.

Fernandes et al. reported specific somatic and psychiatric conditions among migrants, particularly women, as a result of deterioration of their mental health status of the migrants was reported as poor in Odisha and they were facing uncertainty for future living prospects. The large number of published articles highlighted the need for psychosocial and mental health care for migrants.

Discussion

The present review represents literature about the psychosocial and mental health issues of the migrants during contemporary pandemic times. At the time of COVID-19 pandemic outbreak in India, the migrants constituted the most vulnerable group for developing psychosocial and mental health issues, given their economic and stressful environmental situations. The research findings have been synthesized from different parts of India. A systematic review was not feasible due to the small number and heterogeneous nature of studies, variability in the number of participants, and variable living conditions of migrants in different states of India. Thus, a narrative review was undertaken.

The majority of studies elucidated multiple psychosocial issues and some authors reported about usefulness of brief psychosocial support. Living conditions, basic needs, housing, transport facility, family concern, risk of infection, issues of children and women, poverty, unemployment, and insecurity about future were predominant psychosocial issues reported. The social support indicators were found to have a positive impact on the mental status of migrants. The joblessness issues were also looked at in a cross-sectional study. The psychosocial impact of joblessness was observed more in elderly migrants. Some studies reported poor mental health care in states like Odisha, Bihar, and Uttar Pradesh. The migrants received optimal social security measures in Kerala.

The prevalence of substance use was found to be higher among migrants than the general population. The prevalence of at least one psychiatric diagnosis was 19% among reverse migrants. The prevalence of ever use for all the substances was 44%, ever use of alcohol was 16%, and the current use of alcohol was 11% among the migrants. In a study from North India, 73% of the migrants screened positive for at least one psychiatric disorder. Fifty-one percent of the migrants screened positive for both depression and anxiety. The majority of findings revealed severe mental stress, starvation, suicide, and roadside accidents among migrants. Basic psychosocial measures in the form of a multidisciplinary approach for minimizing various crisis situations were attempted, with positive outcomes.
mental health and psychosocial status. The specific conditions were back-
ache, shoulder pain, headache, various psychiatric disorders, and suicide. In
the present review, somatic-specific conditions and sex-specific reports
were lacking. The previous interna-
tional studies of mental health issues
among migrants were more focused
on first-generation migrants coming
from low-income countries and previ-
ous researchers studied cross-cultural
issues. Zhong et al.41 found that psy-
chological distress was more prevalent
in the newer rather than older genera-
tion migrants (36.2% vs. 28.2%). In
the present review conducted in the period
of COVID-19, the cross-cultural issues
and psychiatric morbidity among first
or second-generation migrants were not
separately reported, though it would
have given a better understanding of
the psychosocial status of migrants.

Implications for Policy and Research

There was no uniform national policy
or strategy to handle the migrant crisis
in India during the COVID-19 pan-
demic.19,35 The state health authorities
adopted the psychosocial support mea-
sures, which were initially sluggish
in some states, with a lack of concern
related to migrant distress during the
pandemic crisis.6 The COVID-19 pan-
demic crisis raised several lessons for
social scientists, policy planners, and
mental health experts. This review will
help them in better understanding of
the various psychosocial and mental issues
of migrants during this crisis.19

To reach the unreached migrant popu-
lation, policy planners should think and
plan of regular registration facilities and
mobile apps for migrants. An integrated
mental health awareness drive among
them also helped them in utilizing
various psychosocial and mental health
services and social welfare schemes
by the Government of India.35,42 The
migrant population should be incorpo-
rated into the mainstream of general
population by providing them social,
legal, health, and occupational secu-
rity.35,42 It was found that the destination
state’s social protective policy played an
important role in resolving the psycho-
social issues of the migrants.14 Poverty
measurements serve as justification for
state social protection measures. It is
to identify the poor migrants and
deliver social welfare schemes to them.
The long-term mental health implication
of this migrant crisis needs to be
further studied so that proper policy
decision could be taken in future pan-
demic conditions. Government schemes
of One Nation One Ration Card should
be implemented on a priority basis.15 In
a future eventuality, migrant popula-
tion’s social measures must be kept in
mind in disaster planning so that their
sufferings could be minimized. Decen-
tralization is an important strategy to
provide services to the migrants.19,33

Health insurance scheme needs to be ini-
tiated, better coordination needs to be
ensured between government agencies
and migrants population, and housing
conditions need to be addressed so that
migrants are able to live in dignity,
peace, security, and safety.11,13,15,19,41 The
present review suggests the need for
more research in this area and the adop-
tion of mental health and psychosocial
intervention for migrants in clinical
practice at various levels.

Limitations

This review has some methodological
limitations, which include small sample
sizes, weak statistical analyses, and limited
scope of some studies. Only nine studies
were original research. The published
literature mostly comprised commentar-
ies, viewpoints, editorials, opinions, and
letters to the editor. The studies were less
in number. Further long-term multicenter
studies with standardized assessments
and large sample size are warranted to rep-
llicate the findings of this review.

Conclusion

Majority of research articles highlighted
the need for psychosocial and mental
health care for migrants. Predominant psy-
chosocial issues found among migrants
were living conditions, basic needs, risk of
infection, issues of children and women,
family concerns, joblessness, transport and
housing facilities, and future insecurity.
The mental health issues found included
psychological distress, depressive disor-
ders, anxiety disorders, and substance use
disorders. Brief psychosocial interventions
and integrated comprehensive mental
health care approach for migrants were
found useful in resolving their mental and
psychosocial issues.

Declaration of Conflicting Interests

The authors declared no potential conflicts of
interest with respect to the research, authorship,
and/or publication of this article.

Funding

The authors received no financial support for the re-
search, authorship, and/or publication of this article.
