THE A·B·C·Ds OF SCHUBERT CALCULUS

COLLEEN ROBICHAX, HARSHIT YADAV, AND ALEXANDER YONG

ABSTRACT. We collect Atiyah-Bott Combinatorial Dreams (A·B·C·Ds) in Schubert calculus. One result relates equivariant structure coefficients for two isotropic flag manifolds, with consequences to the thesis of C. Monical. We contextualize using work of N. Bergeron-F. Sottile, S. Billey-M. Haiman, P. Pragacz, and T. Ikeda-L. Mihalcea-I. Naruse. The relation complements a theorem of A. Kresch-H. Tamvakis in quantum cohomology. Results of A. Buch-V. Ravikumar rule out a similar correspondence in K-theory.

1. INTRODUCTION

1.1. Conceptual framework. Each generalized flag variety $G/B$ has finitely many orbits under the left action of the (opposite) Borel subgroup $B_-$ of a complex reductive Lie group $G$. They are indexed by elements $w$ of the Weyl group $W \cong N(T)/T$, where $T = B \cap B_-$ is a maximal torus. The Schubert varieties are closures $X_w$ of these orbits. The Poincaré duals of the Schubert varieties $\{\sigma_w\}_{w \in W}$ form a $\mathbb{Z}$-linear basis of the cohomology ring $H^*(G/B)$. The Schubert structure coefficients are nonnegative integers, defined by

$$\sigma_u \cdot \sigma_v = \sum_{w \in W} c_{u,v}^w \sigma_w.$$ 

Geometrically, $c_{u,v}^w \in \mathbb{Z}_{\geq 0}$ counts intersection points of generic translates of three Schubert varieties. The main problem of modern Schubert calculus is to combinatorially explain this positivity. For Grassmannians, this is achieved by the Littlewood-Richardson rule [13].

The title alludes to a principle, traceable to M. Atiyah-R. Bott [6], that equivariant cohomology is a lever on ordinary cohomology. In our case, each $X_w$ is $T$-stable, so it admits a class $\xi_w$ in $H^*_T(G/B)$, the $T$-equivariant cohomology ring of $G/B$. These classes form a basis for $H^*_T(G/B)$ as a module over the base ring $H^*_T(pt)$. If $\Delta = \{\alpha_1, \ldots, \alpha_r\}$ are the simple roots of the root system $\Phi = \Phi^+ \cup \Phi^-$ associated to our pinning of $G$, $H^*_T(pt) \cong \mathbb{Z}[\alpha_1, \ldots, \alpha_r]$.

Define the equivariant Schubert structure coefficient $C_{u,v}^w \in H^*_T(pt)$ by

$$(1) \quad \xi_u \cdot \xi_v = \sum_{w \in W} C_{u,v}^w \xi_w.$$ 

If $\ell(u) + \ell(v) = \ell(w)$, $C_{u,v}^w = c_{u,v}^w$. Thus we have a harder version of the main problem, with $\# \Delta$-many parameters. Does the equivariant complication make the problem simpler? This study initiates our systematic exploration of the question.

The inclusion $(G/B)^T \hookrightarrow G/B$ induces an injective map

$$(2) \quad H^*_T(G/B) \hookrightarrow H^*_T((G/B)^T) \cong \bigoplus_{w \in W} \mathbb{Z}[\alpha_1, \ldots, \alpha_r].$$

Thus, each $\xi_w$ is identified with a $\# W$-size list of polynomials $(\xi_w|_v)_{v \in W}$. Multiplication in $H^*_T(G/B)$ is thereby pointwise multiplication of these lists. Moreover, there is a formula

Date: June 9, 2019.
for the equivariant restriction $\xi_w|_v$ due to H. Andersen-J. Jantzen-W. Soergel [4], and rediscovered by S. Billey [8]. Let $I = s_{\alpha_1}s_{\alpha_2}\cdots s_{\alpha_{\ell}(v)}$ be a reduced word for $v \in W$, where $s_{\alpha_i}$ is the reflection through the hyperplane perpendicular to $\alpha_i := \alpha_j \in \Delta$ (for some $j$ depending on $i$). Then,

$$
(3) \quad \xi_{w}|_v = \sum_{J \subseteq I} \prod_{i \in J}(\alpha_{\langle i \in J \rangle}\alpha_i) \cdot 1;
$$

cf. [21, Theorem 1]. The sum is over subwords $J$ that are reduced words for $w$. Also, $\alpha_{\langle i \in J \rangle}$ means $\alpha_i$ appears only if $i \in J$. Combining (3) and (2) provides the combinatorial definition of $H^*_T(G/B)$ we use.

This description of $H^*_T(G/B)$ permits a non-positive linear algebraic computation of $C^w_{u,v}$, see, e.g., [8, Section 6]. From this perspective, the solved combinatorics of equivariant restriction and the open problem of Schubert calculus seem far apart. However, we argue using an idealization that the concepts are closer than first supposed:

**Atiyah-Bott Combinatorial Dream (A·B·C·D).** A combinatorial (positivity) statement true of equivariant restrictions also holds for Schubert structure coefficients.

We begin with retrospective examples:

(I) Sometimes combining (3) with basic Coxeter theory realizes an A·B·C·D. Bruhat order $\leq$ on $W$ is geometrically defined by $w \leq v$ if $X_w \supseteq X_v$. Fix a reduced word $I$ of $v$. The subword property of Bruhat order states that $w \leq v$ if and only if there exists a subword $J$ of $I$ that is a reduced word of $w$. Hence from (3),

$$
(4) \quad \xi_{w}|_v = 0 \quad \text{unless} \quad w \leq v.
$$

Combining (4) and (2) gives

$$
(5) \quad C^w_{u,v} = 0 \quad \text{unless} \quad u \leq w \quad \text{and} \quad v \leq w.
$$

(II) The converse of A·B·C·D is true. Following [21, Lemma 1], by (4) and (5),

$$
\xi_{v}|_v : \xi_{w}|_v = C^w_{v,w} \cdot \xi_{v}|_v.
$$

By (3), $\xi_{v}|_v \neq 0$. Hence

$$
(6) \quad C^w_{v,w} = \xi_{w}|_v.
$$

This is a tantalizing clue about an eventual combinatorial rule for $C^w_{u,v}$. More concretely, in [24], (6) implies a recurrence that, with additional combinatorics, proves an equivariant Littlewood-Richardson rule sans symmetric functions.

(III) Here is a deep instance ([8], cf. [39, Section 2]). It is textbook [17, Section 1.7] that

$$
\text{Inv}(v^{-1}) := \{\alpha \in \Phi^+ : v^{-1}(\alpha) \in \Phi^-\} = \{s_{\alpha_1}s_{\alpha_2}\cdots s_{\alpha_{\ell-1}}\alpha_k : 1 \leq k \leq \ell(v)\}.
$$

Since each positive root is a positive linear combination of simples, by (7) and (3),

$$
\xi_{w}|_v \in \mathbb{Z}_{\geq 0}[\alpha_1, \ldots, \alpha_r].
$$

Indeed, D. Peterson conjectured, and W. Graham [15] geometrically proved that

$$
(8) \quad C^w_{u,v} \in \mathbb{Z}_{\geq 0}[\alpha_1, \ldots, \alpha_r].
$$

---

1Equivariant restriction is part of GKM-theory [14], a subject of extensive investigation; see, e.g., J. Tymoczko’s exposition [39], and the references therein, for an account germane to our discussion. However the case of Schubert varieties is found in work of B. Kostant-S. Kumar [25, 26].
(IV) This is closely related to (III), but is folklore. Since \( \ell(v) = \ell(v^{-1}) = \# \text{Inv}(v^{-1}) \), by (7), \( s_{\alpha_1} s_{\alpha_2} \cdots s_{\alpha_{n-1}} \alpha_k \in \Phi^+ \) are all distinct. Hence from (3), \( \xi_{w|v} \) is square-free when expressed in the positive roots. As A. Knutson (private communication) points out, the proof in [15] shows this to be true of \( C_{u,v}^w \) as well.

(V) For any \( G/B \), there is a recurrence, due to B. Kostant and S. Kumar to compute \( \xi_w|_v \), it has an analogue for \( C_{u,v}^w \) due to A. Knutson. See [22, Theorem 1] and [21, Section 1]. In turn, special cases of Knutson’s recurrence give “descent cycling” relations on the ordinary Schubert structure constants [20].

1.2. Does A·B·C·D suggest anything new? Our main instance is of different flavor than (I)-(V). We relate all structure coefficients of one isotropic flag variety to those of another; this has consequences. The results are neither explicit in the literature nor seem well-known. The correspondence generalizes, with a new proof, non-equivariant results of P. Pragacz [34] and of N. Bergeron-F. Sottile [7] (who rely on S. Billey-M. Haiman’s work [9], which in turn generalizes [34]). We emphasize that the correspondence can also be derived from T. Ikeda-L. Mihalcea-H. Naruse’s [18]; see the discussion of Section 3.

Consider the classical groups \( G = \text{SO}_{2n+1} \) and \( G = \text{Sp}_{2n} \) of non-simply laced type. These are automorphism groups preserving a non-degenerate bilinear form \( \langle \cdot, \cdot \rangle \). In the former case it is a symmetric form on \( W = \mathbb{C}^{2n+1} \) whereas in the latter case it is a skew symmetric form on \( W = \mathbb{C}^{2n} \). A subspace \( V \subseteq W \) is isotropic if, for all \( v_1, v_2 \in V \), \( \langle v_1, v_2 \rangle = 0 \). The maximum dimension of an isotropic space is \( n \). Any flag of isotropic subspaces \( \{ 0 \} \subset F_1 \subset F_2 \subset \cdots \subset F_n \) extends to a complete flag in \( W \) by \( \langle 0 \rangle \subset F_1 \subset F_2 \subset \cdots \subset F_n \subset F_n^+ \subset F_n^+ \subset \cdots \subset F_1^+ \subset W \), where \( F_k^+ \) is the orthogonal complement of \( F_k \). Then the flag manifolds \( X = \text{SO}_{2n+1}/B \) and \( Y = \text{Sp}_{2n}/B \) consist of complete flags of this form.

The root systems for \( \text{SO}_{2n+1} \) (type \( B_n \)) and \( \text{Sp}_{2n} \) (type \( C_n \)) are rank \( r = n \). Let \( \{ \beta_1, \ldots, \beta_n \} \) and \( \{ \gamma_1, \ldots, \gamma_n \} \) be the simples labelled by their respective Dynkin diagrams

\[
\begin{array}{cccccccccccccccccccc}
1 & 2 & 3 & \cdots & n-1 & n \\
\end{array}
\quad \text{and} \quad
\begin{array}{cccccccccccccccccccc}
1 & 2 & 3 & \cdots & n-1 & n \\
\end{array}
\]

The two root systems share the hyperoctahedral group \( B_n \) as their common Weyl group. We represent \( B_n \) as signed permutations of \( \{ 1, 2, \ldots, n \} \), e.g., \( 2 \ 1 \ 3 \). Define

\[
s(w) := \# \{ 1 \leq i \leq n : w(i) < 0 \}.
\]

Let \( \overline{f} \in \mathbb{Z}[\beta_1, \beta_2, \ldots, \beta_n] \) be \( f \in \mathbb{Z}[\gamma_1, \gamma_2, \ldots, \gamma_n] \) with \( \gamma_1 \mapsto 2 \beta_1 \) and \( \gamma_i \mapsto \beta_i \) for \( 1 < i \leq n \).

**Theorem 1.1.** \( C_{w,v}^w(X) = 2^{s(w) - s(u) - s(v)} C_{u,v}^w(Y) \).

**Proof.** This equivalence is from the definitions:

\[
\xi_{w}(Y)|_{x} = \sum_{J \subseteq I} \prod_{i} (\gamma_{(i \in J)} s_{\Delta_{i}}) \cdot 1 \iff \xi_{w}(Y)|_{x} = \sum_{J \subseteq I} \prod_{i} (\beta_{(i \in J)} s_{\Delta_{i}}) \cdot 1.
\]

The Coxeter combinatorics needed is merely this: since \( J \) is a reduced word for \( w \), it is true that \( \# \{ 1 \in J \} = s(w) \). Therefore,

\[
\xi_{w}(Y)|_{x} = 2^{s(w)} \sum_{J \subseteq I} \prod_{i} (\beta_{(i \in J)} s_{\Delta_{i}}) \cdot 1 = 2^{s(w)} \xi_{w}(X)|_{x};
\]

i.e., a “power of two relationship” between the restrictions. Applying (1), (2) and (3) to \( Y \),

\[
\xi_{u}(Y)|_{x} \cdot \xi_{v}(Y)|_{x} = \sum_{w \in B_n} C_{u,v}^w(Y) \xi_{w}(Y)|_{x} \quad \forall x \in B_n
\]
\[ \xi_u(Y)|_x \cdot \xi_v(Y)|_x = \sum_{w \in B_n} C^{w}_{u,v}(Y) \xi_w(Y)|_x \quad \forall x \in B_n \]

\[ \left(2^{-s(u)}\xi_u(Y)|_x\right) \cdot \left(2^{-s(v)}\xi_v(Y)|_x\right) = \sum_{w \in B_n} 2^{s(w)-s(u)-s(v)} C^{w}_{u,v}(Y) \left(2^{-s(w)}\xi_w(Y)|_x\right) \quad \forall x \in B_n \]

\[ = \xi_u(X)|_x \cdot \xi_v(X)|_x = \sum_{w \in B_n} 2^{s(u)-s(v)} C^{w}_{u,v}(Y) \xi_w(X)|_x \quad \forall x \in B_n \quad [\text{by (9)}]. \]

We are now done by (1), (2) and (3) applied to \( X \), i.e., uniqueness of the equivariant structure coefficients. \[ \square \]

**Example 1.2.** Consider \( u = 321, v = 321 \) and \( w = 231 \) in \( B_3 \). Then \( s(w) = s(u) = 1 \) and \( C_{u,v}(Y) = 2\gamma_1\gamma_2^2 + 2\gamma_1\gamma_2\gamma_3 + 4\gamma_2\gamma_3^2 + 6\gamma_2^2\gamma_3 + 2\gamma_2\gamma_3^2 \), so

\[ C_{u,v}(Y) = 4\beta_1\beta_2^2 + 4\beta_1\beta_2\beta_3 + 4\beta_3^3 + 6\beta_2\beta_3 + 2\beta_2\beta_3^2. \]

We also have

\[ C_{u,v}(X) = 2\beta_1\beta_2^2 + 2\beta_1\beta_2\beta_3 + 2\beta_3^3 + 3\beta_2\beta_3 + \beta_2\beta_3^2. \]

Hence \( C_{u,v}(X) = 2^{-1}C_{u,v}(Y) \), in agreement with Theorem 1.1. \[ \square \]

Since the correspondence of Theorem 1.1 respects Graham-positivity,

**Corollary 1.3.**

\[ [\beta_1^{i_1} \cdots \beta_n^{i_n}] C_{u,v}(X) = 0 \iff [\gamma_1^{i_1} \cdots \gamma_n^{i_n}] C_{u,v}(Y) = 0. \]

In particular, \( C_{u,v}(X) = 0 \iff C_{u,v}(Y) = 0. \)

Let \( X' = OG(n, 2n+1) \) be the maximal orthogonal Grassmannian of \( n \)-dimensional subspaces of \( \mathbb{C}^{2n+1} \) that are isotropic with respect to a nondegenerate symmetric form. Also, let \( Y' = LG(n, 2n) \) be the Lagrangian Grassmannian of \( n \)-dimensional subspaces of \( \mathbb{C}^{2n} \) that are isotropic with respect to a nondegenerate skew-symmetric form. A *strict partition* is an integer partition \( \lambda = (\lambda_1 > \lambda_2 > \ldots > \lambda_t) \). The Schubert varieties and their (equivariant) cohomology classes are indexed by such \( \lambda \) with \( \lambda_1 \leq n \) and \( \ell \leq n \). Let \( \ell(\lambda) \) be the number of (nonzero) parts of a strict partition \( \lambda \).

**Corollary 1.4 (cf. Conjecture 5.1 of [32]).** \( C_{\lambda,\mu}(X') = 2^{\ell(\nu)-\ell(\lambda)-\ell(\mu)} C_{\lambda,\mu}(Y'). \)

**Proof.** The map \( X \to X' \) that forgets all subspaces of a complete flag in \( X \) except the \( n \)-th induces \( H_T(X') \to H_T(X) \) sending Schubert classes to Schubert classes. The image of \( \xi_{\lambda}(X') \) is \( \xi_{w_{\lambda}}(X) \) where \( w_{\lambda} \in B_n \) is the unique ascending signed permutation beginning as \( -\lambda_1, -\lambda_2, \ldots, -\lambda_t \), followed by positive integers in increasing order. Therefore, \( C_{\lambda,\mu}(X') = C_{w_{\lambda},w_{\mu}}(X) \). Similarly, \( C_{\lambda,\mu}(Y') = C_{w_{\lambda},w_{\mu}}(Y) \). Hence, the result follows from Theorem 1.1 since by definition of \( w_{\lambda}, \ell(\lambda) = s(\lambda_{\lambda}). \)

**Example 1.5.** Let \( n = 3 \) and \( \lambda = (3, 2), \mu = (2, 1) \), and \( \nu = (3, 2, 1) \). Then \( \ell(\nu) - \ell(\lambda) - \ell(\mu) = -1 \). Now, \( C_{\lambda,\mu}(Y') = 3\gamma_1^2 + 10\gamma_1\gamma_2 + 8\gamma_2^2 + 5\gamma_1\gamma_3 + 8\gamma_2\gamma_3 + 2\gamma_3^2 \), so

\[ C_{\lambda,\mu}(Y') = 12\beta_1^2 + 20\beta_1\beta_2 + 8\beta_2^2 + 10\beta_1\beta_3 + 8\beta_2\beta_3 + 2\beta_3^2. \]

We also have

\[ C_{\lambda,\mu}(X') = 6\beta_1^2 + 10\beta_1\beta_2 + 4\beta_2^2 + 5\beta_1\beta_3 + 4\beta_2\beta_3 + \beta_3^2, \]

so \( C_{\lambda,\mu}(X') = 2^{-1}C_{\lambda,\mu}(Y') \), agreeing with Corollary 1.4. \[ \square \]

\[ ^2 \text{Hence } w_{\lambda} = 321 = s_2 s_1 s_3 s_2 s_1, w_{\mu} = 213 = s_1 s_2 s_1 \text{ and } w_{\nu} = 221 = s_1 s_2 s_1 s_3 s_2 s_1. \]
Corollary 1.4 says that the open problems of giving (Graham positive) combinatorial rules to compute $C_{\lambda,\mu}^{\nu}(X')$ and $C_{\lambda,\mu}^{\nu}(Y')$ are equivalent.

Moreover, Corollary 1.4 makes exact a conjecture stated in the thesis of C. Monical [32, Conjecture 5.1]. In that thesis, one also finds [32, Conjecture 5.3], a conjectural recursive rule (cf. [32, Conjecture 5.3]) that extends work of A. Klyachko [19] and A. Knutson-T. Tao [23] on the eigenvalue problem for sums of Hermitian matrices. Corollary 1.4 proves:

**Corollary 1.6.** (cf. [32, Conjecture 5.3]) C. Monical’s inequalities characterize $C_{\lambda,\mu}^{\nu}(X') \neq 0$ if and only if they characterize $C_{\lambda,\mu}^{\nu}(Y') \neq 0$.

Here is another consequence of Theorem 1.1. C. Li-V. Ravikumar [30] prove equivariant Pieri rules for (submaximal) isotropic Grassmannians of classical type $B, C, D$. Their type $B$ and $C$ rules are proved by separate geometric analyses. Theorem 1.1 immediately implies a Pieri rule for type $C$ from the type $B$ rule (or vice versa).

The "power of two" relationship between $X'$ and $Y'$ does not hold (in any obvious way) in the Grothendieck ($K$-theory) ring of algebraic vector bundles; see work of A. Buch-V. Ravikumar [11, Examples 4.9, 5.8]. On the other hand, Theorem 1.1 may be compared to the quantum cohomology result of A. Kresch-H. Tamvakis [28, Theorem 6].

### 2. More examples of A·B·C·D

#### 2.1. Inclusion of Dynkin diagrams

Suppose we have an inclusion of (finite) Dynkin diagrams $D \hookrightarrow E$ where the nodes $1, 2, \ldots, r(D)$ of $D$ are sent to the nodes $1^\circ, 2^\circ, \ldots, r(D)^\circ$ of $E$, respectively. Let

$$\Delta(D) = \{\alpha_1, \ldots, \alpha_{r(D)}\} \text{ and } \Delta(E) = \{\beta_1^\circ, \ldots, \beta_{r(D)^\circ}, \beta_{r(D)+1}^\circ, \ldots, \beta_{r(E)^\circ}\}.$$

Given $w \in \mathcal{W}(D)$ we can unambiguously define $w^\circ \in \mathcal{W}(E)$ by taking a reduced word $I$ for $w$ and replacing $s_{\alpha_i}$ with $s_{\beta_i^\circ}$ to obtain a reduced word $I^\circ$ for $w^\circ$. Let

$$\psi_{D,E} : [\mathbb{Z}[\alpha_1, \ldots, \alpha_{r(D)}] \rightarrow [\mathbb{Z}[\beta_1^\circ, \ldots, \beta_{r(D)^\circ}]]$$

be defined by $\alpha_i \mapsto \beta_i^\circ$.

**Theorem 2.1.** $\psi_{D,E}(C_{w^\circ}(D)) = C_{w^\circ}(E)$.

**Proof.** We start with the restriction version of the statement, i.e.,

**Claim 2.2.** $\psi_{D,E}(\xi_{w}(D)|_w) = \xi_{w^\circ}(E)|_{w^\circ}$.

**Proof of Claim 2.2:** This is immediate from (3) using $I$ and $I^\circ$ respectively in computing $\xi_{w}(D)|_w$ and $\xi_{w^\circ}(E)|_{w^\circ}$. This is since the inclusion of Dynkin diagrams induces a canonical isomorphism of the root system of $D$ with a subroot system of $E$ that maps $\alpha_i$ to $\beta_i^\circ$, and a canonical isomorphism of $\mathcal{W}(D)$ with the parabolic subgroup $\mathcal{W}(E)_D$ of $\mathcal{W}(E)$ generated by $s_{\beta_i^\circ}$ for $1 \leq i \leq r(D)$; see, e.g., [17, Section 5.5].

**Claim 2.3.** If $w \in \mathcal{W}(E) - \mathcal{W}(E)_D$ and $v \in \mathcal{W}(D)$ then $\xi_{w}(E)|_{v^\circ} = 0$. 

---

3a (multi)-graph theoretic injection that respects arrows
Proof of Claim 2.3: Since \( w \in \mathcal{W}(E) - \mathcal{W}(E)_{D_r} \), by definition any reduced word for \( w \) involves a \( s_{\beta_i} \) for some \( t > r(D) \). Fix any reduced word \( I^o \) of \( v^o \). Since \( v^o \in \mathcal{W}(E)_{D_r} \), \( I^o \) does not involve \( s_{\beta_i} \). Hence no subword of \( I^o \) can be a reduced word for \( w \). Now the claim follows from (3). \( \square \)

Combining Claims 2.2 and 2.3 implies that for any \( u, v, x \in \mathcal{W}(D) \),
\[
\xi(E)_{u|v} \cdot \xi(E)_{v|x} = \sum_{w^o \in \mathcal{W}(E)_{D}} C^{w^o}_{u^o,v^o}(E) \xi(E)_{w^o|x} \quad \forall x \in \mathcal{W}(D).
\]

By Claim 2.2, for all \( y \in \mathcal{W}(D) \),
\[
\xi(E)_{y|v} \in \mathbb{Z}_{\geq 0}[\beta_1, \ldots, \beta_{r(D)}].
\]

Therefore by this nonnegativity and W. Graham's theorem (8), it must be that
\[
C^{w^o}_{u^o,v^o}(E) \in \mathbb{Z}_{\geq 0}[\beta_1, \ldots, \beta_{r(D)}].
\]

Therefore, it makes sense to apply \( \psi^{-1}_{D,E} \) to both sides of (10) to obtain
\[
\xi(D)_{u|v} \cdot \xi(D)_{v|x} = \sum_{w \in \mathcal{W}(D)} \psi^{-1}_{D,E}(C^{w^o}_{u^o,v^o}(E)) \xi(D)_{w|x} \quad \forall x \in \mathcal{W}(D).
\]

We can now conclude as in the proof of Theorem 1.1. By uniqueness of the structure constants, (11) asserts
\[
\psi^{-1}_{D,E}(C^{w^o}_{u^o,v^o}(E)) = C^{w}_{u,v}(D).
\]

Apply \( \psi_{D,E} \) to both sides to conclude the proof. \( \square \)

Example 2.4. The Dynkin diagram for \( F_4 \) is \( 1 \overset{2}{\longrightarrow} 3 \overset{4}{\longrightarrow} \). Now, there is an embedding of \( D = B_3 \) into \( E = F_4 \), given by \( 1 \mapsto 1^o = 2, 2 \mapsto 2^o = 3, 3 \mapsto 3^o = 4 \). One computes that
\[
C^{s_1s_2s_1s_1}_{s_1s_2s_1s_1s_2}(B_3) = 2\beta_1^2 + 3\beta_1 \beta_2 + 2 \beta_2^2 \quad \text{and} \quad C^{s_2s_1s_4s_2}_{s_2s_3s_2s_3s_4s_2}(F_4) = 2 \zeta_2^2 + 3 \zeta_2 \zeta_3 + \zeta_3^2.
\]

These are equal after \( \beta_i \mapsto \zeta_{i+1} \) for \( 1 \leq i \leq 3 \), in agreement with the Theorem 2.1. \( \square \)

Besides being computationally useful, Theorem 2.1 is a guiding property in the search for an eventual combinatorial rule for \( C^{w}_{u,v} \). See [37, Section 5.2] for hints of this in the root-system uniform (non-equivariant) rule for the special case of minuscule flag varieties.

There are coincidences between types \( B_n \) and \( D_{n+1} \), since the Dynkin diagram of the former is the “folding” of the Dynkin diagram for the latter:
\[
\begin{array}{c}
\overset{2}{\longrightarrow} \\
\overset{3}{\longrightarrow} \\
\overset{4}{\longrightarrow} \\
\overset{\cdots}{\longrightarrow} \\
1 \\
n \quad n+1
\end{array}
\]

Example 2.5. \( C^{s_1s_2s_1}_{s_1s_2s_1s_1s_2s_1}(B_2) = \beta_1(2\beta_1 + \beta_2)(\beta_1 + \beta_2) \). It is natural to compare \( s_1s_2s_1 \in \mathcal{W}(B_2) \) with \( s_1s_3s_2 \in \mathcal{W}(D_3) \). Indeed,
\[
C^{s_1s_3s_2}_{s_1s_3s_2s_1s_3s_2}(D_3) = \delta_1(\delta_1 + \delta_2 + \delta_3)(\delta_1 + \delta_3)
\]
equals \( C^{s_1s_2s_1}_{s_1s_2s_1s_2s_1s_2}(B_2) \) under the “folding substitution” \( \delta_1, \delta_2 \mapsto \beta_1 \) and \( \delta_3 \mapsto \beta_2 \). \( \square \)

Such a substitution gives a correspondence between \( \text{OG}(n, 2n + 1) \) restrictions and a subset of restrictions of \( \text{OG}(n + 1, 2n + 2) \) (the maximal isotropic Grassmannian of type \( D_{n+1} \)); see [16, Remark 5.7] and the references therein. By the A-B-C-D argument as in Theorem 1.1, one obtains a correspondence of structure coefficients. Unfortunately, this correspondence is not true in general, even for restrictions:
Example 2.6. One calculates that
\[ \xi_{s_{2}s_{1}s_{2}s_{3}}(B_{3}) = 4\beta_{1}^{2}\beta_{2} + 10\beta_{1}^{2}\beta_{2}^{2} + 2\beta_{2}^{2}\beta_{3} + 8\beta_{1}\beta_{2}^{3} + 3\beta_{1}\beta_{2}\beta_{3} + 2\beta_{2}^{4} + \beta_{2}\beta_{3}. \]
By direct search, there is no \( \xi_{v}(D_{4}) \) which, after the folding substitution \( \delta_{1}, \delta_{2} \mapsto \beta_{1}, \delta_{3} \mapsto \beta_{2}, \delta_{4} \mapsto \beta_{3} \), has even the same monomial support as \( \xi_{s_{2}s_{1}s_{2}s_{3}}(B_{3}) \). \( \square \)

2.2. Nonvanishing. The result is known, cf. [8, Corollary 4.5] which credits [25]. We include a proof to be self-contained.

Proposition 2.7. \( \xi_{w}|_{v} \neq 0 \) for all \( w \leq v \leq w_{0} \).

Proof. Suppose \( v \leq v' \) and fix a reduced word \( I' \) for \( v' \). By the subword property of Bruhat order, there is a subword \( I \) of \( I' \) which is reduced for \( v \). Any subword \( J \) of \( I \) that is a reduced word for \( w \) is also a subword of \( I' \). Thus, by (3), any monomial appearing in \( \xi_{w}|_{v} \) associated to \( J \) corresponds to a maybe different monomial (in the positive roots) in \( \xi_{w}|_{v'} \). Now use that (3) says \( \xi_{w}|_{w} \) is a nonzero monomial. \( \square \)

Conjecture 2.8 (A-B-C-D version of Proposition 2.7). Assume \( C^{w}_{u,v} \neq 0 \).

(I) \( C^{w}_{u,s_{a}v} \neq 0 \) when \( v < s_{a}v \leq w \) and \( \alpha \in \Delta \).

(II) If \( \ell(w) < \ell(u) + \ell(v) \) then there exists \( s_{\alpha} (\alpha \in \Delta) \) with \( s_{\alpha}v < v \) such that \( C^{w}_{u,s_{a}v} \neq 0 \).

Example 2.9. In Conjecture 2.8, the existential quantification in (II) is needed. In type \( B_{3} \),
\[ C^{s_{2}s_{1}s_{3}}_{s_{2}s_{3},s_{1}s_{3}} = \beta_{2} + \beta_{3}, \quad \text{but} \quad C^{s_{2}s_{1}s_{3}}_{s_{2}s_{3},s_{1}s_{3}}(s_{1}s_{3}) = 0. \]
Now, \( C^{s_{2}s_{1}s_{3}}_{s_{2}s_{3},s_{1}s_{3}} = 1 \), as predicted. \( \square \)

We exhaustively checked Conjecture 2.8 for \( A_{4}, B_{3} \) and \( G_{2} \) and for many examples in \( A_{5}, B_{4} \) and \( F_{4} \). Conjecture 2.8 holds for Grassmannians, where it plays a key role in [3], which connects [12] to the equivariant structure coefficients. C. Monical’s extension, discussed in Section 1, motivates this conjecture.

Example 2.10. There is no “righthand version” of either part of Conjecture 2.8. For (I),
\[ C^{s_{1}s_{2}s_{1}}_{s_{1}s_{2},s_{1}}(A_{2}) = 1 \quad \text{but} \quad C^{s_{1}s_{2}s_{1}}_{s_{1}s_{2},s_{1}}(s_{1}s_{2}) = 0. \]
Whereas for (II), \( C^{s_{1}s_{2}s_{1}}_{s_{1}s_{2},s_{1}}(A_{2}) = \alpha_{1} + \alpha_{2} \) yet \( C^{s_{1}s_{2}s_{1}}_{s_{1}s_{2},s_{1}s_{2}}(s_{1}s_{2}) = 0. \) \( \square \)

Proposition 2.7 implies that, for the classical types, the decision problem Restriction “\( \xi_{w}|_{v} \neq 0? \)” is in the class \( P \) of polynomial time problems.\(^4\) This is since there is a polynomial time tableau criterion for deciding if \( w \leq v \) for corresponding Weyl groups; see [10, Chapters 2, 8] (here the input size is bounded by a polynomial in \( r \)). The A-B-C-D version of this claim concerns the decision problem Nonvanishing: “\( C^{w}_{u,v} \neq 0? \)” given input \( u, v, w \in W \) (in one line notation).

Conjecture 2.11. For each classical Lie type, Nonvanishing \( \in P \).

Conjecture 2.11 is highly speculative. That said, it holds for Grassmannians [2]. In our opinion, this conjecture is related to the (testable) Conjecture 2.17 given below.

\(^{4}\)For complexity purposes, the exceptional types are ignored since they are finite in number.
2.3. Counterexamples to A·B·C·D. It is interesting to study situations where A·B·C·D is (seemingly) false. For instance, here is a true statement about restrictions:

**Theorem 2.12 (Monotonicity).** If \( w \leq v \leq v' \) then \( \xi_w|_{v'} - \xi_w|_v \in \mathbb{Z}_{\geq 0}[\alpha_1, \ldots, \alpha_r] \).

**Proof.** It suffices to prove this when \( \alpha \) is (completely) false. For instance in \( \mathfrak{c} \), there exists a reduced word of \( w \) such that \( w = w_v \). Therefore by (3),

\[
(\xi_w|_{v'}) - (\xi_w|_v) = s_{i_1} \cdots s_{i_k} \cdot \alpha_{i_k} \in \Phi^+.
\]

Hence, by (8), \( (\xi_w|_{v'}) - (\xi_w|_v) = (s_{i_1} \cdots s_{i_k} \cdot \alpha_{i_k})C_{w,v} \in \mathbb{Z}_{\geq 0}[\alpha_1, \ldots, \alpha_r] \), as desired.

**Example 2.13 (Monotonicity counterexample).** Thus, it is tempting to conjecture that if \( u, v, w \) are in \( W \) and \( s_{\alpha} \) is a simple reflection such that \( u \leq us_{\alpha} := v' \) and \( w \leq ws_{\alpha} := w' \) then \( C_{w',v'} - C_{w,v} \in \mathbb{Z}_{\geq 0}[\alpha_1, \ldots, \alpha_r] \). In particular, this would imply \( C_{w',v'} \geq C_{w,v} \). However, that is false in general. For instance in \( A_3 \), if \( u = 351624, v = 214356, w = 635124 \) and \( s = s_3 \) \( C_{w,uv} = 351624, 214356 = 1 \) but \( C_{w',uv} = 635124, 214356 = 0 \).

A theorem of A. Arabia [5] states:

\[
\alpha \text{ divides } (\xi_w|_{s_{\alpha}v}) - (\xi_w|_v).
\]

(In general, this is the condition of [14] that describes the image of (2).)

**Example 2.14 (Divisibility counterexample).** Does \( \alpha \) divide \( C_{s_{\alpha}uv} - C_{uv} \)? This is false in general. In type \( A_3 \) let \( u = s_3, v = t_2s_3s_1 \) and \( w = s_2s_3s_1 \). Then \( C_{w,v} = \alpha_2 + \alpha_3 \). Let \( s_{\alpha} = s_1 \) and hence \( s_{\alpha}u = s_1u = s_1s_3, s_{\alpha}w = s_1w = s_1s_2s_3s_1 \). Now \( C_{s_{\alpha}uv} = \alpha_1 + \alpha_2 \), and thus \( C_{s_{\alpha}uv} - C_{uv} = \alpha_1 - \alpha_3 \) is neither \( \alpha \)-positive nor divisible by \( \alpha_1 \).

A number of other simple variations on monotonicity and divisibility are false as well. Can the A·B·C·Ds for monotonicity/divisibility be realized, under a hypothesis?

2.4. Newton polytopes. The Newton polytope of

\[
f = \sum_{(n_1, \ldots, n_r) \in \mathbb{Z}_{\geq 0}^r} c_{n_1, \ldots, n_r} \prod_{j=1}^{r} \alpha_j^{n_j} \in \mathbb{R}^{[\alpha_1, \ldots, \alpha_r]}
\]

is Newton \((f) := \operatorname{conv}\{(n_1, \ldots, n_r) : c_{n_1, \ldots, n_r} \neq 0\} \subseteq \mathbb{R}^r \).

**Proposition 2.15.** Let \( w \in W \) and \( w \leq v \leq v' \). Then \( \text{Newton}(\xi_w|_v) \subseteq \text{Newton}(\xi_w|_{v'}) \).
Proof. This is immediate from Theorem 2.12.

\( f \) has saturated Newton polytope (SNP) [33] if \( c_{n_1, \ldots, n_r} \neq 0 \iff (n_1, \ldots, n_r) \in \text{Newton}(f). \)

Conjecture 2.16. Let \( v, w \in W \), then \( \xi_{w|v} \) has SNP.

Conjecture 2.17 (A·B·C·D version of Conjecture 2.16). Let \( u, v, w \in W \), then \( C_{u|v}^{w} \) has SNP.

We exhaustively checked these conjectures for \( A_4, B_3, D_4, G_2 \) and many examples in \( A_6 \) and \( B_4 \). A proof of either conjecture for Grassmannians would be interesting.

SNP is connected to computational complexity in [1, Section 1]. We suspect the concrete SNP claim of Conjecture 2.17 is the combinatorial harbinger of the \( P \) assertion of Conjecture 2.11. Let \( \text{Schubert} \) be the decision problem "\((n_1, \ldots, n_r) \in \text{Newton}(C_{u|v}^{w})?\)" , given input \( u, v, w \in W \) and \( (n_1, \ldots, n_r) \in \mathbb{Z}_{\geq 0}^r \). It is reasonable to conjecture existence of:

- a combinatorial rule for \( C_{u|v}^{w} \) that moreover implies counting \( C_{u|v}^{w} \) is a problem in the counting complexity class \( \#P \), and
- a halfspace description of \( \text{Newton}(C_{u|v}^{w}) \) where each individual inequality can be checked in polynomial time (even if there are exponentially many inequalities).

Conjecture 2.17 would then imply \( \text{Schubert} \in NP \cap \text{coNP} \). Often problems in \( NP \cap \text{coNP} \) are in fact in \( P \) (see [1, Section 1.2] for a discussion). \( \text{Schubert} \in P \) implies the important case of Conjecture 2.11 for the non-equivariant \( c_{u|v}^{w} \) is true.

3. Comparisons to Schubert Polynomial Theory

The theory of Schubert polynomials, introduced by A. Lascoux and M.-P. Schützenberger [29], is influential in the conversation of positivity in Schubert calculus.

These polynomials “lift” the Schur polynomials from the ring of symmetric polynomials to the ring of all polynomials. The study of Schur polynomials is backed by an extensive literature on Young tableaux, from which one obtains the Littlewood-Richardson rule. Thus one might hope for an analogous theory for Schubert polynomials; this remains unrealized. For the purposes of our discussion, let us call this the “lifting dream”.

Theorem 1.1 generalizes the identity

\[
c_{u,v}^{w}(X) = 2^{s(w)-s(u)-s(v)} c_{u,v}^{w}(Y).
\]

This seems to have been first stated in [7, (3.2)], who rely on the Schubert polynomials for classical groups of S. Billey-M. Haiman [9]. Similarly, Corollary 1.4 generalizes the equality

\[
c_{\lambda,\mu}^{\nu}(X') = 2^{\ell(\nu)-\ell(\lambda)-\ell(\mu)} c_{\lambda,\mu}^{\nu}(Y'),
\]

which is a consequence of P. Pragacz [34, Theorem 6.17] on the Schubert calculus interpretation of the Schur \( Q- \), \( P- \) functions. Theorem 1.1 also follows from T. Ikeda-L. Mihalcea-H. Naruse [18] who give an equivariant generalization of the polynomials of [9].

Over the past three decades, within algebraic combinatorics, the emphasis has been on the Schubert polynomial rather than the list of many restrictions.\(^5\) Our proof replaces the effort of the polynomial constructions [34, 9, 18] with the general geometric result (2).

\(^5\)Not that the two viewpoints are unrelated: in type \( A \) for example, one can compute the restrictions as certain specializations of the double Schubert polynomials; see, e.g., [8].
This work suggests A·B·C·D as an alternative to the “lifting dream” and one that opens up some new and testable possibilities.

Is there concrete evidence for preferring one approach to the other? For example, can one give an A·B·C·D proof of S. Robinson’s equivariant Pieri rule for $\text{GL}_n/B$ [36]? Can one give a Schubert polynomial (in this case, factorial Schur polynomial) proof of one or more of the combinatorial rules [24, 27, 38] by giving an equivariant version of Schensted insertion? Based on earlier conversation of the third author with H. Thomas, this latter question seems quite nontrivial.

ACKNOWLEDGEMENTS

This paper was stimulated by the thesis of Cara Monical [32]; we made use of her related code. We thank the organizers of the Ohio State Schubert calculus conference (May 2018), which facilitated consultation with experts about the conjectures of [32]. Dylan Rupel provided helpful comments about an earlier draft. Sue Tolman explained to us the seminal role of [6] in equivariant symplectic geometry. AY was partially supported by an NSF grant, a U·I·U·C Campus Research Board grant, and a Simons Collaboration Grant. This material is based upon work of CR supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. DGE – 1746047.
