(January 1, 2022)

The string model of gravitational force is proposed where the string forms the mediation of the gravitational interaction between two gravitating bodies. It reproduces the Newtonian results in the first-order approximation and it predicts in the higher-order approximations the existence of oscillations of the gravitational field between two massive bodies. It can be easily generalized to the two-body interaction in particle physics.

I. INTRODUCTION

In history of exact sciences there exist some problems which were formulated some centuries ago and solved only in this century. In mathematics it is for instance the Fermat theorem which was resolved at the recent time. In physics there is the problem of action-at-a-distance which was for the first time formulated by Newton in his "Principia Mathematica" [1] and never solved by him.

While the Fermat theorem is extremely difficult to prove, the action-at-a-distance problem can be solved because it is enough to use approximation. Instead of resolution of this problem Newton suggested the phenomenological theory of the gravitational force where there exists no answer concerning the dynamics or the mechanism of action-at-a-distance. Newton himself was aware that it necessary exists some mediation of interaction between two bodies at the different points in space because he has written [1]: "It is inconceivable, that inanimate brute matter, should without the mediation of something else which is not material, operate upon and affect other matter without mutual contact . . ". In other words, the crucial notion in the Newton speculation is the mediation between two bodies.

By analogy with the mechanical situation we will suppose the model where the attractive force between two bodies is transmitted as tension in the fictitious string connecting the one body with the another one. Then, the theoretical problem is to show that such model works and gives not only the old results but new results which cannot be derived from the original Newton law.

We will consider the string, the left end of which is fixed at the beginning of the coordinate system and mass $m$ is fixed on the right end of the string. The motion of the system string and the body with mass $m$ is the fundamental problem of the equations of the mathematical physics in case that the tension is linearly dependent on elongation [2]. We will show that it is possible to represent the Newton gravitational law by the string with the nonlinear tension in the string. Because of the strong nonlinearity of the problem the motion of the string and the body can be solved only approximately. In the following text we will give the approximate version of the Kepler problem and then we get the string solution of this problem.

II. THE KEPLER PROBLEM

Let us consider two bodies 1 and 2 with masses $M$ and $m$, where $M \gg m$. The body 1 is supposed to be fixed at the origin of the coordinate system and the body 2 is for the simplicity moving in the interval

$$(R - \delta, R + \delta),$$

where $\delta \ll R$, which corresponds to the motion of planets of our Sun system. The Newton law
\[
F = -\kappa \frac{Mm}{r^2},
\]  
(2)
can be obviously expressed in the interval (1) approximately as
\[
F \approx a\eta + b; \ (-\delta, \delta) \ni \eta,
\]  
(3)
where
\[
a = \frac{2\kappa Mm}{R^3}, \quad b = -\frac{\kappa Mm}{R^2}.
\]  
(4)
The motion of body 2 in the gravitational potential of body 1 is described by equation [3]
\[
m \ddot{r} = -\kappa \frac{Mm}{r^2} + \frac{J^2}{m^3r^3},
\]  
(5)
where \(J\) is the angular momentum of body 2. In the interval \((-\delta, \delta)\) we can write
\[
r(t) = R + \eta(t)
\]  
(6)
and using approximation
\[
\frac{1}{(R + \eta)^2} \approx \frac{1}{R^2}(1 - \frac{2\eta}{R}), \quad \frac{1}{(R + \eta)^3} \approx \frac{1}{R^3}(1 - \frac{3\eta}{R}),
\]  
(7)
we get after insertion of eq. (6) into eq. (5):
\[
\ddot{\eta} + \omega^2 \eta = \lambda,
\]  
(8)
where
\[
\omega^2 = \frac{3J^2}{m^2R^4} - \frac{2\kappa M}{R^3}
\]  
(9)
\[
\lambda = \frac{J^2}{m^2R^3} - \frac{\kappa M}{R^2}.
\]  
(10)
For the circle motion we have \(J = m\omega R^2\), \(r = R\) and from eqs. (9) and (10) it follows:
\[
\omega = R^{-3/2}(\kappa M)^{1/2}, \quad \lambda = 0.
\]  
(11)
It is easy to see that the solution of eq. (8) is of the form:
\[
\eta(t) = \Lambda \cos(\omega t + \vartheta) + \frac{\lambda}{\omega^2},
\]  
(12)
where \(\Lambda\) and \(\vartheta\) are constants involving the initial conditions of motion of the body 2.
So far we have supposed no dynamics of mediation of the interaction between body 1 and 2. However, only the model involving the mechanism of mediation of interaction can describe logically consistent reality and explain the Newton puzzle. Let us try to elaborate the consistent and realistic model which describes the mechanism of mediation.
In this section we will solve the motion of a body 2 at the end of the string on the assumption that the tension in the string is nonlinear and it generates the Newton law in the statical regime. We will give the rigorous mathematical formulation of the problem. While for the Hook tension the problem has solution by the Fourier method, in case of the nonlinear tension it is not possible to use this method. There is no evidence about solution of this problem in the textbooks of mathematical physics or in the mathematical journals. So, it seems, we solve this problem for the first time.

Let be given the string, the left end of which is fixed at beginning and the right end is at point \( l \) at the state of equilibrium. The deflection of the string element \( dl \) at point \( x \) and time \( t \) let be \( u(x, t) \) where \( x \in (0, l) \) and

\[ \eta(t) = u(l, t), \quad \eta(0) = u(l, 0). \]  

(13)

Then, the motion of body 2 is described by the motion of the right end-point of the string, when the left point is constantly fixed at the origin.

The differential equation of motion of string elements can be derived by the following way: We suppose that the force acting on the element \( dl \) of the string is given by the law:

\[ T(x, t) = -ES \left( \frac{\partial u}{\partial x} \right)^{-2}, \]

(14)

where \( E \) is the modulus of elasticity, \( S \) is the cross section of the string. We easily derive that

\[ T(x + dx) - T(x) = 2ES (u_x)^{-3} u_{xx} dx. \]

(15)

The mass \( dm \) of the element \( dl \) is \( \rho ES dx \), where \( \rho \) is the mass density of the string matter and the dynamical equilibrium gives

\[ \rho S dx u_{tt} = 2ES (u_x)^{-3} u_{xx} dx. \]

(16)

Putting

\[ \rho = \rho_0 \frac{2}{(u_x)^4}; \quad \rho_0 = const., \]

(17)

we get

\[ \frac{1}{c^2} u_{tt} - u_{xx} = 0; \quad c = \left( \frac{E}{\rho_0} \right)^{1/2}. \]

(18)

The last procedure was performed evidently in order to get the wave equation.

Now, let us look for the correspondence between the string tension and the Newton law. Putting \( u_{tt} = 0 \) we get the stationary case with the solution

\[ u(x, t) = \alpha x + \beta. \]

(19)

Because \( u(0, t) \equiv 0 \), we get \( \beta = 0 \). Then \( u_x(x, t) = \alpha \) is not dependent on \( x \) and according to the definition of the tension the force is constant along the length of the string which is the same result as in the case with the Hook law.

For sufficiently big elongation we have \( u(l) \gg l \) and the elongation at point \( l \) is the distance of the right end of the string from the origin and it means that the force acting on the right end of the string
is proportional to the minus square of the distance of the right end of the string as in the Newton gravitational law. So we have demonstrated that the Newton gravitational force can be simulated by the string however with the difference that in the Newton force there is no mediation between two bodies while in our case we have mediation caused by the medium of the string. Now we can repeat the formulation of the problem described in the previous section in such a way that we will use the dynamical equation (18) instead of eq. (5). So, let us approach the solution of the problem of the motion of body on the end of the string where the tension of the string is defined by equation (14).

From (19) we have:

$$\alpha = \frac{u(l, t)}{l}. \quad (20)$$

Thus,

$$T(l, t) = -\frac{ESl^2}{u^2(l, t)} = -\kappa \frac{mM}{u^2(l, t)}, \quad (21)$$

which gives the relation between the string constants and the gravitating parameters

$$ESl^2 = \kappa mM. \quad (22)$$

The complete solution of eq. (18) includes the initial and boundary conditions. The simplest nontrivial initial conditions can be chosen with regard to the character of the problem and they are:

$$u(x, 0) = \frac{R}{l} x, \quad u_t(x, 0) = 0. \quad (23)$$

The boundary conditions are given with respect to the dynamical equation (5):

$$u(0, t) = 0, \quad mu_{tt}(l, t) = T(l, t) + \frac{J^2}{mu^3(l, t)}. \quad (24)$$

The solution of the wave equation with the strongly nonlinear boundary conditions is evidently beyond the possibility of the present mathematical physics. Nor the Fourier method, nor the d’Alembert one can be used in solution of our problem. So we are forced to find only the approximation of this problem. For this goal we write:

$$u(x, t) = \frac{R}{l} x + v(x, t), \quad (25)$$

from which follows

$$u_x(x, t) = \frac{R}{l} + v_x, \quad u(l, t) = R + v \quad (26)$$

and we suppose that $v \ll R$. In such a way the initial conditions are:

$$v(x, 0) = 0, \quad v_t(x, 0) = 0. \quad (27)$$

The approximative formulae are given in the following form:

$$\frac{1}{w^2_{x}(x, t)} \approx \frac{t^2}{R^2} - \frac{2v_xt^3}{R^3}. \quad (28)$$
\[
\frac{1}{u^4(x,t)} \approx \frac{1}{R^3} - \frac{3v}{R^4}.
\] (29)

So, we get the new problem of mathematical physics: the wave equation

\[
v_{tt} = c^2 v_{xx}
\] (30)

with the initial conditions

\[
v(x,0) = 0; \quad v_t(x,0) = 0
\] (31)

and with the boundary conditions

\[
v(0,t) = 0; \quad mv_{tt}(l,t) = a + bv_x(l,t) + dv(l,t),
\] (32)

where we have put

\[
a = -\kappa \frac{Mm}{R^2} + \frac{J^2}{mR^4}; \quad b = \frac{2\kappa Mm}{R^4} l; \quad d = -\frac{3J^2}{mR^4}.
\] (33)

The equation (30) with the initial and boundary conditions (31) and (32) represents one of the standard problems of the mathematical physics and can be easily solved using the Laplace transform [4]:

\[
\hat{L}u(x,t) \overset{d}{=} \int_0^\infty e^{-pt} u(x,t) dt = u(x,p).
\] (34)

Using (30) we get with \(\hat{L}v(x,t) \overset{d}{=} \phi(x,p)\):

\[
\hat{Lv}_{tt}(x,t) = p^2 \phi(x,p) - pv(x,0) - v_t(x,0) = p^2 \phi(x,p)
\] (35)

\[
\hat{Lv}_{xx}(x,t) = \phi_{xx}(x,p); \quad \hat{L}a = \frac{a}{p}; \quad \hat{L}v(0,t) = \phi(0,p) = 0.
\] (36)

After elementary mathematical operations we get the differential equation for \(\phi\) in the form:

\[
\phi_{xx}(x,p) - k^2 \phi(x,p) = 0; \quad k = p/c.
\] (37)

with the boundary condition in eq. (36).

We are looking for the the solution of eq. (37) in the form

\[
\phi(x,p) = c_1 \cosh kx + c_2 \sinh kx.
\] (38)

We get from the boundary conditions in eq. (36) \(c_1 = 0\) and

\[
c_2 = \frac{a}{p} \frac{1}{(mp^2 - d) \sinh kl - bk \cosh kl}.
\] (39)

The corresponding \(\phi(x,p)\) is of the form:
\[ \varphi(x, p) = \frac{a}{p} \frac{\sinh kx}{(mp^2 - d) \sinh kl - bk \cosh kl} \]  

(40)

The corresponding function \( v(x, t) \) follows from the theory of the Laplace transform as the mathematical formula:

\[
v(x, t) = \frac{1}{2\pi i} \oint e^{pt} \varphi(x, p) dp = \sum_{p=p_n} \text{res } e^{pt} \varphi(x, p) =
\[
\sum_{p=p_n} \text{res } \frac{\sinh kx}{p} \frac{\sinh kx}{(mp^2 - d) \sinh kl - bk \cosh kl},
\]  

(41)

where \( p_n \) are poles of the function \( \varphi(x, p) \) and they are evidently given by equation

\[
[(mp^2 - d) \sinh kl - bk \cosh kl] = 0,
\]  

(42)

which is equivalent with \( k \to ik \) to

\[
\tan kl = \frac{-bk}{mc^2k^2 + d}.
\]  

(43)

In case of \( k \ll 1 \) we have two solutions: \( p_0 = 0 \) and

\[
p_{1/2} = \pm \left( \frac{3J^2}{m^2R^4} - \frac{2kM}{R^3} \right)^{1/2},
\]  

(44)

which is in agreement with eq. (9) obtained by the approximation of classical Kepler problem. Further we have got the oscillations with frequencies \( p_n \) in the higher order approximation:

\[
p_n \to \frac{n\pi}{l}, \quad n \gg 1
\]  

(45)

At present time it is not clear how to detect these oscillations, or, if it will be possible to use the experimental procedures of Braginskii et al. [5] for the detection. However, the analogous situation was in quantum physics where the zero frequencies of vacuum was considered as meaningless till it was shown by Casimir that they give the attractive force between two conductive plates. Thus these frequencies cannot be a priori canceled.

**IV. DISCUSSION**

The basic heuristical idea of this article was the string realization of the gravitational force between two bodies.

In order to realize this idea we introduced the string of the length \( l \) with the nonlinear tension which generates in the statical situation the Newton law at the distances much greater then is the fundamental length of the string. We have solved this problem only approximately because at present time the exact solution is beyond possibilities of mathematics.

While the string with the Hook tension has the equilibrium state, our string is not stable and the stability of the string requires its quantisation. However, the quantization of the string was not problem of our article. We have only shown how to solve the Newton puzzle of gravitation.

In case that we consider the influence of the rotation of the string on the planetary motion, we are forced write for the total energy of the system
\[ E = \frac{m}{2} r^2 + \frac{1}{2} (m + \frac{1}{3} \mu) r^2 \dot{\phi}^2 + U(r), \]  

(46)

where \( \mu \) is the mass of the string and \( \phi \) is the polar coordinate.

Then, after the time-derivation of eq. (46) it follows the corresponding equation of motion of the system and from the Lagrange equations we have:

\[ \ddot{\phi} = \frac{J_{\text{total}}}{(m + \frac{1}{3} \mu) r^2}. \]  

(47)

It means that in principle the existence of the string can be proved experimentally by measurement of \( \dot{\phi} \).

Our problem was never defined to our knowledge in the mathematical or physical textbooks, monographs or scientific journals. Thus, our approach is original. It also enables to formulate the two-body problem with arbitrary nonlinear tension in the string and it can be applied also in particle physics.

The proposed model can be also related in the modified form to the problem of the radial motion of quarks bound by a string and used to calculate the excited states of such system. The original solution was considered by Bardeen et al. [6] Chodos et al. [7] and by Frampton [8]. The new analysis of such problem was performed by Nesterenko [9]. Nobody of these authors used our approach. So there are open way in particle physics to follow our approach.
