We propose how to achieve significantly enhanced quantum refrigeration and entanglement by coupling a pumped auxiliary cavity to an optomechanical cavity. We obtain both analytical and numerical results, and find optimal-refrigeration and -entanglement conditions under the auxiliary-cavity-assisted (ACA) mechanism. Our method leads to a giant amplification in the net refrigeration rate, and reveals that the ACA entanglement has a much stronger noise-tolerant ability in comparison with the unassisted case. By appropriately designing the ACA mechanism, an effective mechanical susceptibility can be well adjusted, and a genuine tripartite entanglement of cooling-cavity photons, auxiliary-cavity photons, and phonons could be generated. Specifically, we show that both optomechanical refrigeration and entanglement can be greatly enhanced for the blue-detuned driving of the auxiliary cavity but suppressed for the red-detuned case. Our work paves a way towards further quantum control of macroscopic mechanical systems and the enhancement and protection of fragile quantum resources.

I. INTRODUCTION

Exploring radiation-pressure interactions between light and mechanical motion in cavity optomechanics [1–4] has lead to an impressive development of efficient methods for generating and controlling photon blockade [5–13], optomechanically induced transparency [14–19], dynamical Casimir effect [20–23], and nonreciprocal excitation transport [24–32]. In particular, optomechanical cooling [33–35] and entanglement [36–43] studied here are, respectively, a prerequisite for observing and manipulating quantum mechanical effects and a key element in quantum information processing.

So far, several cooling mechanisms based on optomechanical systems, such as resolved-sideband cooling [33, 34] and feedback-aided cooling [35, 44–53], have been proposed to cool mechanical resonators to their quantum ground states. To further develop cooling performance, various new cooling schemes have been proposed, such as those based on quantum interference [54–56], parity-time symmetric [57], modulated pulses [58, 59], domino effect [60, 61], strong couplings [62, 63], and nonreciprocity [28, 64]. Particularly, cooling of mechanical resonators has also been simultaneously achieved in optical [65–69] and microwave [70–76] platforms. These theoretical and experimental advances enable the generation of nonclassical mechanical states and the quantum manipulation of macroscopic mechanical systems.

In parallel, optomechanical interfaces also provide a powerful tool for achieving quantum entanglement between, e.g., a cavity-field mode and a mechanical mode, two cavity-field modes, and two mechanical resonators [36–42]. However, this generated entanglement is often limited by the stability conditions of the systems [36–38] and the amplification effect in the unstable regime [77, 78]. In particular, environmental thermal noises can destroy fragile quantum entanglement in practical devices. To generate highly pure quantum entanglement, reservoir engineering techniques [79–85], quantum interference effect [86–91], time modulation of the driving laser [92–95], photon counting techniques [96], and Sagnac effect [97], have been proposed based on cavity optomechanical systems. Despite such achievements, the enhancement of both optomechanical cooling and entanglement, and the protection of fragile quantum correlations in practical devices still need further studies.

In this paper, we again study how to significantly enhance the performances of refrigeration and entanglement in an auxiliary-cavity-assisted optomechanical system, revealing the robustness of the ACA entanglement against thermal noises. Inspired by optomechanical cooling and entanglement in a single-cavity setup [33–36], we generalize the approach for a two-cavity system, where a pumped auxiliary cavity is coupled to an optomechanical cavity. Our study differs from what is known in the double-cavity literature because we are interested not in an EIT-like mechanism [88–90], but in a pumped-auxiliary-device engineering. Using both analytical and numerical calculations based on the ACA mechanism, more than a ten-fold improvement can be achieved for the net cooling rate, and the amplification factor almost linearly depends on the pump power of the auxiliary cavity. Physically, the ACA mechanism can significantly amplify the effective optomechanical coupling strength and considerably speed up the refrigeration process. Additionally, we show that by appropriately designing the ACA mechanism, an effective susceptibility of the mechanical resonator can be tuned largely. Moreover, by assuming experimentally reachable parameters, we find that cooling-cavity photons, auxiliary-cavity photons, and phonons can be entangled with each other, such that the steady state of the system exhibits a genuine tripartite entanglement.

In particular, a significant enhancement can be achieved for optomechanical cooling, quantum entanglement, and noise tolerance of quantum resources. Remarkably, the cooling
performance of the mechanical resonator in the ACA case is 40% higher than in cases without the auxiliary cavity. Physically, the optomechanical cooling is mainly governed by the net cooling rate, which directly determines the extraction efficiency of the thermal excitations stored in the mechanical resonator. The multiply amplified net cooling rate leads to a significant enhancement of the cooling performance of the resonator. We find that, for the blue-detuned driving of the auxiliary cavity, both optomechanical cooling and entanglement are significantly enhanced; while for the red-detuned case, are suppressed. Moreover, in comparison with the auxiliary-cavity-unassisted case, our ACA optomechanical entanglement has a stronger ability against thermal noises. We also reveal that due to the joint effect of optomechanical and tunneling couplings, the indirectly coupled cavity photons and phonons can be entangled strongly, and the robustness of quantum entanglement against thermal noises is even up to three times that of the directly coupled case. These results provide the possibility to enhance or steer the optomechanical refrigeration and entanglement, manipulate macroscopic mechanical coherence, generate nonclassical mechanical states, as well as enhance and protect fragile quantum resources against thermal noise.

The rest of this paper is organized as follows. In Sec. II, we present the ACA optomechanical model and its Hamiltonians. In Sec. III, we derive the Langevin equations, obtain the analytical and numerical results of steady-state average phonon numbers, and calculate the logarithmic negativity. In Sec. IV, we analyze the cooling performance. In Sec. V, we study bipartite and tripartite entanglements. Finally, we conclude in Sec. VI. Two Appendixes include the detailed calculations of the steady-state mean phonon numbers and the bistability analysis.

II. MODEL AND HAMILTONIAN

We consider an ACA optomechanical system, where a pumped auxiliary cavity is coupled to a standard optomechanical cavity through a tunneling coupling, as illustrated in Fig. 1(a). A mechanical resonator is coupled to the cooling-cavity field via radiation-pressure coupling. A monochromatic laser with frequency $\omega_L$ ($\omega_R$) and field amplitude $\Omega_L$ ($\Omega_R$) is applied to drive the cooling (auxiliary) cavity, so that the optical and mechanical degrees of freedom can be manipulated. The Hamiltonian of the system reads ($\hbar = 1$)

$$
\mathcal{H} = \omega_c a_c^\dagger a_c + \omega_a a_a^\dagger a_a + \frac{P_s^2}{2m} + \frac{ma_a^2x^2}{2} - ga_a x \omega_c x + J(a_c^\dagger a_a + a_c a_a^\dagger) + \Omega_L (a_c^\dagger e^{i\omega_lt} + a_c e^{-i\omega_lt}) + \Omega_R (a_a a_c^\dagger + a_a^\dagger a_c), \tag{1}
$$

where $a_c$ and $a_a$ ($a_c^\dagger$ and $a_a^\dagger$) are the annihilation (creation) operators of the cooling-cavity and auxiliary-cavity field modes with resonance frequencies $\omega_c$ and $\omega_a$, respectively. The mechanical resonator is described by the momentum $p_x$ and position $x$ operators with mass $m$ and resonance frequency $\omega_m$. The $g$ term in Eq. (1) describes the optomechanical coupling between the mechanical resonator and the cavity field, where $g = \omega_c / L$ is the strength of a single-photon radiation-pressure force, with $L$ being the rest length of the optical cavity. The tunneling coupling (with strength $J$) between the two cavity-field modes is described by the $J$ term. The last two terms in Eq. (1) describe, respectively, the laser driving for the cooling and auxiliary cavities. Their amplitudes are $\Omega_L = \sqrt{2P_Lk_c/\omega_L}$ and $\Omega_R = \sqrt{2P_Rk_a/\omega_R}$, with $P_L$ ($P_R$) and $k_c$ ($k_a$) being the driving power and the cavity-field decay rate for the cooling (auxiliary) cavity, respectively. Note that the photon-tunneling interaction

![FIG. 1. (a) Schematics of the optomechanical system. A cooling cavity $a_c$ with resonance frequency $\omega_c$ is, respectively, coupled to a mechanical resonator with the position operator $x$, via radiation-pressure coupling with strength $g$, and to an auxiliary cavity through the tunneling coupling with strength $J$. A monochromatic laser with frequency $\omega_L$ ($\omega_R$) and field amplitude $\Omega_L$ ($\Omega_R$) is introduced to drive the cooling (auxiliary) cavity. (b) Effective mechanical frequency $\Omega_{\text{eff}}(\omega)$ [see Eq. (22a)] and (c) effective mechanical damping $\gamma_{\text{eff}}(\omega)$ [see Eq. (22b)] versus the Fourier frequency $\omega$ in the auxiliary-cavity-unassisted ($J = 0$, blue solid curves) and -assisted ($J/\omega_m = 0.15$ and $P_R = 50$ mW, red dashed curves) cases. The parameters are: $\Delta = \omega_m, \Delta_c = 0, \omega_a/2\pi = 10$ MHz, $\kappa_c/\omega_m = \kappa_a/\omega_m = 0.1, \gamma_m/\omega_m = 10^{-5}, \omega_c/\omega_m = 2.817 \times 10^4, P_L = 30$ mW, $m = 250$ ng, $n = 10^3$, $L = 0.5$ mm, and $J = 1064$ nm.](image)
between the two cavity-field modes can be realized by optical backscattering [97, 98]. This backscattering of the photons is induced by the surface roughness and material defects in practical devices. Therefore, in realistic systems, the value of the photon-tunneling coupling used in our simulations should be of the same order of the decay rates of the cavity-field modes [97, 98].

For convenience, we introduce the dimensionless coordinate and momentum operators \( q = \sqrt{\hbar \omega_m} x \) and \( p = p_x / \sqrt{\hbar \omega_m} \) (\( \{ q, p \} = i \)). In a rotating frame defined by \( \exp(-iQ_t a_c - i \omega_R t a_a) \) with \( \omega_L = \omega_R \), Hamiltonian (1) becomes

\[
H_I = \Delta_c a_c^\dagger a_c + \Delta_d a_d^\dagger a_d + \frac{\omega_m}{2}(q^2 + p^2) - g_0 a_c^\dagger a_c q \\
+ J(a_c^\dagger a_d + a_d^\dagger a_c) + \Omega_d(a_c^\dagger + a_c) + \Omega_R(a_d^\dagger + a_d),
\]

where \( \Delta_c = \omega_c - \omega_L \) (\( \Delta_d = \omega_a - \omega_R \)) and \( g_0 = g / \sqrt{\hbar \omega_m} \) are, respectively, the driving detuning of the cooling (auxiliary) cavity field and the strength of the optomechanical coupling expressed in terms of the dimensionless momentum and coordinate operators.

### III. Langevin Equations and Steady-State Mean Phonon Numbers

In this section, we derive the quantum Langevin equations of the system and obtain the steady-state average phonon numbers in the mechanical resonator.

#### A. Langevin equations

To include the damping and noise effects in this system, we consider the case where the optical mode is coupled to a vacuum bath and the mechanical mode is subjected to the quantum Brownian force. In this case, the evolution of the system can be described by the quantum Langevin equations

\[
\dot{q} = \omega_m p, \quad \dot{p} = -\omega_m q - \gamma_m p + g_0 a_c^\dagger a_c + \xi, \quad \dot{a}_c = -[\kappa + i(\Delta_c - g_0 q)]a_c - i\Omega_d a_c - i\Omega_R + \sqrt{2\kappa} a_{c,in}, \quad \dot{a}_d = -[\kappa + i(\Delta_d - g_0 q)]a_d - i\Omega_d a_d - \sqrt{2\kappa} a_{d,in},
\]

where \( \gamma_m \) is the decay rate of the mechanical resonator. The operators \( \xi \) and \( a_{c,in} \) (\( a_{d,in} \)), respectively, denote the Brownian force acting on the mechanical resonator and the noise operator of the cooling (auxiliary) cavity. These noise operators have zero mean values and have the following correlation functions [35, 99],

\[
\langle a_{c,in}(t) a_{c,in}^\dagger(t') \rangle = \delta(t - t'), \quad \langle a_{c,in}^\dagger(t) a_{c,in}(t') \rangle = 0, \quad \langle a_{d,in}(t) a_{d,in}^\dagger(t') \rangle = \delta(t - t'), \quad \langle a_{d,in}^\dagger(t) a_{d,in}(t') \rangle = 0,
\]

\[
\langle \xi(t) \xi(t') \rangle = \frac{\gamma_m}{\omega_m} \int_{-\infty}^{\infty} e^{-i\omega(t-t')} \omega \left[ \coth \left( \frac{\omega}{2k_B T} \right) + 1 \right] d\omega = \frac{1}{2k_B T} \int_{-\infty}^{\infty} e^{-\omega(t-t')} d\omega.
\]

where \( k_B \) is the Boltzmann constant and \( T \) is the reservoir temperature associated with the mechanical resonator. The correlation function in Eq. (4c) becomes a standard white noise input with delta correlations for sufficiently high temperatures \( k_BT \gg \hbar \omega_m \). This function can be approximated by \( \langle \xi(t) \xi(t') \rangle \approx (2n + 1)g_0 \delta(t - t') \), where the initial mean thermal excitation number of the mechanical resonator is given by \( n = 1/\left[ \exp(\hbar \omega_m/k_BT) - 1 \right] \approx k_BT/\hbar \omega_m \). To cool this mechanical resonator, we consider the strong-driving regime for both cavities, so that our physical model can be simplified by a linearization procedure. Then, we write the operators in Eq. (3) as sums of the steady-state averages and the quantum fluctuations and the classical motion, the linearized quantum Langevin equations become

\[
\begin{align}
\delta \dot{q} &= \omega_m \delta p, \\
\delta \dot{p} &= -\omega_m \delta q - \gamma_m \delta p + G\delta a_c + G\delta a_d^\dagger + \xi, \\
\delta \dot{a}_c &= -\kappa \delta a_c + i\delta \dot{q} - i\delta \dot{p} + i\Omega_d a_c + \sqrt{2\kappa} a_{c,in}, \\
\delta \dot{a}_d &= -\kappa \delta a_d - i\delta \dot{q} + \sqrt{2\kappa} a_{d,in},
\end{align}
\]

where \( \omega_m \) and \( \gamma_m \) are the variances of the momentum and position noise, respectively, and \( G = g_0/\hbar \omega_m \) is the normalized detuning of the cooling cavity, and \( G = g_0/\hbar \omega_m \) is the effective optomechanical coupling. Here \( \langle a_{c,in} \rangle = -i(\Omega + J(a_{c,in})/(\kappa + i\Delta_c)) \) and \( \langle a_{d,in} \rangle = -i(\Omega_R + J(a_{d,in})/(\kappa + i\Delta_d)) \). Note that we have chosen the phase reference of the cavity field, such that \( \langle a_c \rangle \) is real and positive.

#### B. Analytical and numerical steady-state mean phonon numbers

Now, we derive both analytical and numerical results of the steady-state mean phonon numbers in the mechanical resonator.

1. **Analytical steady-state average phonon numbers**

The steady-state average phonon numbers of the mechanical resonator can be obtained by the relation [35, 60]

\[
n_f = \frac{1}{2} \left[ \langle \delta p^2 \rangle + \langle \delta q^2 \rangle - 1 \right],
\]

where \( \langle \delta p^2 \rangle \) and \( \langle \delta q^2 \rangle \) are the variances of the momentum and position operators, respectively. We obtain these variances by solving Eq. (5) in the frequency domain, and integrating the corresponding fluctuation spectra [35, 99],

\[
\langle \delta q^2 \rangle = \frac{1}{2\pi} \int_{-\infty}^{\infty} S_q(\omega) \omega d\omega, \quad \langle \delta p^2 \rangle = \frac{1}{2\pi} \int_{-\infty}^{\infty} S_p(\omega) \omega d\omega,
\]

where the fluctuation spectra of the momentum and position operators are defined by

\[
S_q(\omega) = \int_{-\infty}^{\infty} e^{-i\omega t} \langle \delta \dot{q}(t+\tau) \delta \dot{q}(t) \rangle d\tau, \quad (q = q, p).
\]
In the frequency domain, the fluctuation spectra can also be expressed as
\[
\langle \delta \hat{a}(\omega) \delta \hat{a}(\omega') \rangle_{ss} = S_a(\omega) \delta(\omega + \omega').
\] (9)

According to Eqs. (6) and (7), exact results of the steady-state average thermal excitations can be obtained analytically, which is presented in detail in the Appendix.

2. Numerical steady-state average phonon numbers

Now, we introduce the annihilation (creation) operator for the mechanical resonator \(b = (q + ip)/\sqrt{2} [b^\dagger = (q - ip)/\sqrt{2}\) and then study the cooling performance by numerically evaluating the final mean phonon number. After performing the linearization, the linearized quantum Langevin equations can be rewritten as the following compact form

\[
\dot{\mathbf{u}}(t) = \mathbf{A}\mathbf{u}(t) + \mathbf{N}(t),
\] (10)

where the fluctuation operator vector \(\mathbf{u}(t) = (\delta \hat{a}_c, \delta \hat{b}, \delta \hat{a}_d, \delta \hat{a}_e, \delta \hat{b}^\dagger, \delta \hat{a}_f^\dagger)^T\) and the noise operator vector \(\mathbf{N}(t) = (\sqrt{2\kappa_c} \delta \hat{a}_c, \sqrt{2\gamma_m} \delta \hat{b}, \sqrt{2\kappa_d} \delta \hat{a}_d, \sqrt{2\gamma_m} \delta \hat{b}^\dagger, \sqrt{2\kappa_e} \delta \hat{a}_e, \sqrt{2\gamma_m} \delta \hat{b}^\dagger)^T\), and the coefficient matrix \(\mathbf{A}\):

\[
\mathbf{A} = \begin{pmatrix}
-\bar{\kappa} & -i\mathcal{G} & -iJ & 0 & -i\mathcal{G} & 0 \\
-i\mathcal{G}^* & -\bar{\gamma}_m & 0 & -i\mathcal{G} & 0 & 0 \\
-iJ & 0 & -\bar{\kappa} & 0 & 0 & 0 \\
i\mathcal{G}^* & 0 & 0 & -\bar{\kappa} & i\mathcal{G} & iJ \\
iJ & 0 & 0 & i\mathcal{G} & -\bar{\gamma}_m & 0 \\
0 & 0 & 0 & iJ & 0 & -\bar{\kappa}
\end{pmatrix}
\] (11)

where \(\mathcal{G} = G/\sqrt{2}\) and \(\bar{\gamma}_m = \gamma_m + i\omega_m\). We then obtain the formal solution of the linearized Langevin equation (10),

\[
\mathbf{u}(t) = \mathbf{M}(t)\mathbf{u}(0) + \int_0^t \mathbf{M}(t - s)\mathbf{N}(s)ds,
\] (12)

where \(\mathbf{M}(t) = \exp(\mathbf{A}t)\). From Eq. (12), the steady-state mean phonon number of the mechanical resonator can be calculated by solving the Lyapunov equation. In the following calculations, all the parameters satisfy the stability conditions which are derived based on the Routh-Hurwitz criterion, i.e., the real parts of all the eigenvalues of \(\mathbf{A}\) are negative. Additionally, we have confirmed that for the left pump power \(P_L < 35\) mW, only a single stable solution exists and the compound system has no bistability (see the stability analysis in Appendix B).

Mathematically, the steady-state mean phonon number can be obtained by calculating the steady-state value of the covariance matrix \(\mathbf{V}\), defined by the matrix elements

\[
V_{ij} = \frac{1}{2}\langle \mathbf{u}_i(\infty)\mathbf{u}_j(\infty) \rangle + \langle \mathbf{u}_j(\infty)\mathbf{u}_i(\infty) \rangle, \quad i, j = 1 - 6.
\] (13)

Under the stability conditions, the steady-state covariance matrix \(\mathbf{V}\) fulfills the Lyapunov equation

\[
\mathbf{AV} + \mathbf{VA}^T = -\mathbf{Q},
\] (14)

where the superscript \(T\) represents transposition and

\[
\mathbf{Q} = \frac{1}{2}(\mathbf{C} + \mathbf{C}^T),
\] (15)

with \(\mathbf{C}\) being the noise correlation matrix defined by the matrix elements

\[
\langle \mathbf{N}_i(s)\mathbf{N}_j(s') \rangle = C_{i,j}\delta(s - s').
\] (16)

For the Markovian bath considered in our work, the constant matrix \(\mathbf{C}\) is expressed as

\[
\mathbf{C} = \begin{pmatrix}
0 & 0 & 0 & 2\kappa & 0 & 0 \\
0 & 0 & 0 & 0 & 2\gamma_m & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 2\gamma_m & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}
\] (17)

By calculating the covariance matrix \(\mathbf{V}\), we obtain the steady-state mean phonon number

\[
n_f = \langle \delta \hat{b}^\dagger \delta \hat{b} \rangle = \mathbf{V}_{22} - \frac{1}{4},
\] (18)

where \(\mathbf{V}_{22}\) is obtained by solving the Lyapunov equation (14).

IV. ACA OPTOMECHANICAL COOLING

In this section, we study the ACA cooling by analyzing the effective mechanical susceptibility, the net laser-cooling rate, and the noise spectra.

A. Analytical results of the effective susceptibility and net cooling rate

We obtain the position fluctuation spectrum of the mechanical resonator as

\[
S_q(\omega) = |\chi_{\text{eff}}(\omega)|^2\left[ S_{\text{sp}}(\omega) + S_{\text{th}}(\omega) \right],
\] (19)

where \(\chi_{\text{eff}}(\omega)\) is the effective susceptibility of the mechanical resonator, given by

\[
\chi_{\text{eff}}(\omega) = \omega_m[\Omega_{\text{eff}}^2(\omega) - \omega^2 - i\omega\Gamma_{\text{eff}}(\omega)]^{-1},
\] (20)

with \(\Omega_{\text{eff}}(\omega)\) and \(\Gamma_{\text{eff}}(\omega)\) being, respectively, the effective resonance frequency and damping rate of the mechanical resonator, defined as

\[
\Omega_{\text{eff}} = \sqrt{\omega_m^2 - 2|G|^2 \omega_m(\varphi \Pi + 2\Delta \kappa \Pi^2 \Phi)/\zeta},
\] (21a)

\[
\Gamma_{\text{eff}} = \gamma_m + \gamma_c.
\] (21b)

Here, \(\gamma_c\) denotes the net cooling rate of the mechanical resonator, defined as

\[
\gamma_c = 2|G|^2 \omega_m(2\Delta \kappa \Pi - \varphi \Phi)/\zeta,
\] (22)
and other parameters are

\[ \Pi = \beta_\omega T_\omega + \tau_\omega T_\omega, \quad (23a) \]
\[ \Phi = 2[k^2k_\omega + \mathcal{J}(k_\omega + \kappa_\omega) + \kappa_\omega(\Delta^2 - \omega^2) + \kappa_\omega(\Delta^2 - \omega^2 + \Delta', \omega)], \quad (23b) \]
\[ \zeta = (\beta^2 + \tau^2)(\beta^2 + \tau^2), \quad (23c) \]
\[ \varphi = \mathcal{J}_\omega - \Delta(\kappa_\omega - \omega^2 + \Delta'), \quad (23d) \]

with

\[ \beta_\omega = \pm \sqrt{2} \kappa_\omega \pm \kappa_\omega \pm \Delta(\omega \pm \Delta), \quad (24a) \]
\[ \tau_\omega = \kappa_\omega(\omega \pm \Delta) + \kappa_\omega(\omega \pm \Delta). \quad (24b) \]

In Eq. (19), the thermal noise spectrum \( S_{\omega}(\omega) \) is given by,

\[ S_{\omega}(\omega) = \frac{\gamma_\omega \omega}{\omega_m} \coth \left( \frac{\hbar \omega}{2k_BT} \right), \quad (25) \]

and the radiation-temperature noise spectrum \( S_{\omega}(\omega) \) is so complicated that we don’t show it here.

**B. Amplified net cooling rate**

In the preceding subsection, the effective mechanical resonance frequency \( \Omega_{\text{eff}} \), mechanical damping rate \( \Gamma_{\text{eff}} \) [see Eq. (21)], and the expression of the steady-state average thermal excitation [see Eq. (A1)] have been analyzed analytically. Now, we study how the ACA mechanism improves the cooling performance by analyzing the effective decay rate \( \Gamma_{\text{eff}} \) and mechanical resonance frequency \( \Omega_{\text{eff}} \).

When the system works in the auxiliary-cavity-unassisted \( (J = 0, \text{see solid curves}) \) and-assisted \( (J \omega_m = 0.2 \text{ and } P_R = 30 \text{ mW, see dashed curves}) \) cases, we plot the effective mechanical resonance frequency \( \Omega_{\text{eff}} \) and decay rate \( \Gamma_{\text{eff}} \) as a function of the frequency \( \omega \), as shown in Figs. 1(b) and 1(c). We find that the modification of the mechanical frequency, mainly determined by the optomechanical coupling shown in Eq. (21a), is the so-called “optical spring effect”, which may lead to significant frequency shifts in the case of low-frequency mechanical resonators. However, for our higher-resonance frequency \( (\omega_m/2\pi = 10 \text{ MHz}) \), the optical spring term in Eq. (21a) does not significantly alter the mechanical frequency, i.e., \( \Omega_{\text{eff}} \approx \omega_m \) when \( \omega/\omega_m = \pm 1 \) [see Fig. 1(b)]. Moreover, we show in Fig. 1(c) that by using the ACA mechanism, \( \Gamma_{\text{eff}} \) is significantly increased at \( \omega = \pm \omega_m \). For example, when we switch the unassisted to assisted cases, the effective mechanical decay rate \( \Gamma_{\text{eff}} \) at \( \omega = \pm \omega_m \) can be increased from \( \approx 10^5 \gamma_m \) to \( \approx 4.5 \times 10^5 \gamma_m \). This giant enhancement of the effective mechanical damping \( \Gamma_{\text{eff}} \) plays an important role in improving the cooling performance of the mechanical resonator.

To further understand the underlying physics of the ACA cooling, we consider the red-sideband resonance case, i.e., \( \Delta = \omega_m \) and \( \omega = \omega_m \), and then define a net-cooling-rate amplification factor

\[ \Lambda = \frac{\gamma_{\text{assisted}}}{\gamma_{\text{unassisted}}}, \quad (26) \]

In Fig. 2(a), we plot the net-cooling-rate amplification factor \( \Lambda \) with respect to the tunneling coupling \( J \) and the pump power \( P_R \) of the auxiliary cavity. It shows that the ACA method can significantly amplify the net cooling rate of the mechanical resonator. For example, in the unassisted case (i.e., when \( J = 0 \)), there is no cooling-rate amplification (i.e., \( \Lambda = 1 \), while in the assisted case, the amplification of the net cooling rate emerges and even the amplification factor can increase up to \( \Lambda = 15 \). In particular, when \( P_R \rightarrow 0 \) and \( J/\omega_m \rightarrow 0.6 \), we obtain \( 0 < \Lambda < 1 \) [see the upper left corner in Fig. 2(a)], which is due to the optical backscattering losses in practical devices. Physically, various imperfections of devices, such as material defects and surface roughness, can induce backscattering of photons, as described by the tunneling coupling \( J \) [97, 98]. In a recent experiment [100], a dynamical suppression of backscattering was already observed by breaking the time-reversal symmetry with Brillouin devices. The dependence of the net-cooling-rate amplification factor \( \Lambda \) on the tunneling coupling \( J \) between the two cavities is shown in Fig. 2(b). We find that in the region \( 0 < J/\omega_m < 0.25 \) (0.25 < \( J/\omega_m < 0.5 \)), \( \Lambda \) increases (decreases) with increasing \( J \), and the optimal
be accelerated, by utilizing the ACA mechanism. This study detuning an ACA optomechanical system is to find the optimal driving In Fig. 3. (a) Steady-state average phonon number of the mechanical resonator versus driving detuning \( \Delta_a \) of the pumped auxiliary cavity. For the optimal cooling \( \Delta_a \approx 0 \). Other parameters are the same as those used in Fig. 1.

amplification factor emerges at \( J/\omega_m = 0.25 \). Particularly, in comparison with the typical optomechanical systems, a proportional amplification of the net cooling rate can be observed with the pump power \( P_R \) when \( J \approx 0.2 \omega_m \) [see Figs. 2(c)]. Physically, the effective optomechanical coupling strength can be amplified and the refrigeration process can be accelerated, by utilizing the ACA mechanism. This study provides a new strategy to improve the net cooling rate of the mechanical resonator by just using a pumped auxiliary device.

C. ACA optomechanical cooling

The foremost task of studying cooling properties in such an ACA optomechanical system is to find the optimal driving detuning \( \Delta_a \) and decay rate \( \kappa_a \) of the pumped auxiliary cavity. In Fig. 3(a) we show the steady-state average phonon numbers \( n_f \) of the mechanical resonator versus driving detuning \( \Delta_a \) of the pumped auxiliary cavity. We find a significant enhancement for the cooling performance for blue-detuned driving, \( \Delta_a < 0 \), and that the optimal cooling is located at \( \Delta_a = 0 \). In contrast, the red-detuned driving, \( \Delta_a > 0 \), leads to the suppression of the cooling efficiency. Here, the black horizontal solid line denotes the auxiliary-cavity-unassisted case, i.e., \( J = 0 \). Additionally, we plot the steady-state mean phonon numbers \( n_f \) as a function of the decay rate \( \kappa_a \) of the auxiliary cavity, as shown in Fig. 3(b). We can see that the optimal cooling efficiency of the mechanical resonator emerges in \( 0.5 < \kappa_a/\kappa_c < 1 \). Note that our numerical (marked by symbols) and analytical (solid curves) results exhibit an excellent agreement, as shown in Fig. 3. These results indicate a large improvement of the cooling performance, which is realized by an appropriate design of the auxiliary cavity.

In Fig. 4(a) the final average phonon numbers \( n_f \) are plotted as a function of the effective driving detuning \( \Delta \) of the cooling cavity when the system works in both the auxiliary-cavity-unassisted (see the blue curve) and -assisted (see the red curve) regimes. We can see that when the system is in the assisted case, the cooling performance is much better than that in the unassisted case [see Fig. 4(a)]. This is because the use of the pumped auxiliary cavity can significantly amplify the net-cooling rate of the mechanical resonator and, then, considerably improve its refrigeration performance. Note that for the unassisted case, the mechanical resonator is cooled in the same manner as in a typical optomechanical sideband-cooling scheme [33–35]. The optimal driving detuning is located at \( \Delta \approx \omega_m \), which indicates the maximum energy extraction efficiency between the cooling-cavity-field mode and the mechanical resonator.

In realistic simulations, we find a small deviation of the exact value of \( \omega_m \). This is caused by the counter-rotating-wave term in the linearized coupling between the cooling-cavity field and the mechanical resonator. The underlying physics is that the generation of an anti-Stokes photon leads to the cooling of the mechanical resonator by taking away a phonon from this resonator. For the optimal cooling \( \Delta \approx \omega_m \), the frequency \( \omega_m \) of the phonon exactly matches the driving detuning \( \Delta \), and hence \( \Delta \approx \omega_m \) corresponds to the optimal cooling.

To further elucidate this cooling improvement, we plot the final average phonon numbers \( n_f \) as functions of the tunneling coupling \( J \) and the pump power \( P_R \) of the auxiliary cavity, as shown in Fig. 4(b). By using the ACA mechanism, the mechanical resonator can be cooled efficiently (\( n_f \ll 1 \)), and the lowest final average occupancies are 0.09, which is much smaller than that of the auxiliary-cavity-unassisted case. We can see from Figs. 4(c) and 4(d) that the cooling performance is fully unchanged (see the black dashed lines, \( n_f = 0.15 \)) in the unassisted case, but in stark contrast is improved strongly (see the solid curves and symbols, \( n_f = 0.09 \)) in the assisted case. Note that the numerical (symbols) and analytical (solid curves) results show an excellent agreement, as seen in Figs. 4(c) and 4(d).

To study how large the significant improvement of the cooling performance can be reached, we here introduce a cooling-performance improvement rate \( \chi \), defined as

\[
\chi = \frac{n_{f,\text{assisted}} - n_{f,\text{unassisted}}}{n_{f,\text{unassisted}}}. \tag{27}
\]

Based on Eq. (27), we investigated the dependence of the
cooling-performance improvement rate $\chi$ on the parameters $J$ and $P_R$, as shown in Fig. 5. We can see for the ACA system, that the rate $\chi$ can reach 40% compared with the unassisted case, and that the optimal cooling performance is for: $0.07 < J/\omega_m < 0.2$ and $35 < P_R < 140$ mW. Physically, the optomechanical cooling is mainly governed by the net cooling rate, which directly determines the extraction efficiency of thermal excitations stored in the mechanical resonator and, therefore, the greatly amplified net cooling rate leads to a significant improvement of the cooling performance.

In the above simulations, we have found that the optimal cooling performance is observed at $\Delta \approx \omega_m$ [see Fig. 3(a)], corresponding the maximum phonon extraction efficiency. Thus, based on our analytical expression in Eq. (A1) of the final mean phonon number, the analytical result of the minimum occupation number can be achieved by setting $\Delta = \omega_m$ and $\gamma_m = 0$. However, the analytical expression of the minimum occupation number is so complicated that we do not show it here. Below, we study this by numerical simulations.

Under the optimal effective driving detuning, $\Delta \approx \omega_m$, we plot the steady-state average phonon number $n_f$ as a function of the mechanical decay rate $\gamma_m$ in the auxiliary-cavity-unassisted (blue solid curve) and auxiliary-cavity-assisted ($J/\omega_m = 0.15$ and $P_R = 50$ mW, red solid curve) cases, as shown in Fig. 6(a). We find that in both unassisted and assisted cases, the redundant single-phonon probability could be further suppressed by choosing the mechanical resonator with a smaller decay rate. Physically, the thermal phonon extraction rate (between the mechanical resonator and its heat bath) is faster for a larger value of the mechanical decay rate, and, then, the thermal excitations in the heat bath increase the phonon numbers in the mechanical resonator. In particular, we observe that the cooling efficiency of the mechanical resonator in the assisted case is higher than that of the unassisted case (i.e., $n_{f,\text{assisted}} < n_{f,\text{unassisted}}$), and that the minimum occupation number of the resonator in the assisted case is smaller than that in the unassisted case when $\gamma_m \rightarrow 0$. This is because our ACA mechanism can significantly amplify the effective optomechanical coupling strength and considerably improve the refrigeration performance.

In Fig. 6(b), the final steady-state mean phonon number $n_f$ is plotted as a function of the cavity-field decay rate $\kappa_c$ when the system operates in both unassisted and assisted cases. To clearly study the influence of the sideband-resolution condition on the cooling performance, we also choose the mechanical frequency $\omega_m$ as the frequency scale. We can see that in both unassisted and assisted cases, the phonon sidebands can be well resolved from the cavity-emission spectrum when $\kappa_c/\omega_m < 1$ [see the left area of the dashed back line in Fig. 6(b)], which is called the resolved-sideband limit. In the unresolved-sideband regime $\kappa_c/\omega_m > 1$, the cooling performance of the mechanical resonator becomes much worse for a larger cavity-field decay rate $\kappa_c$ [see the right area of the dashed back line in Fig. 6(b)]. This is due to the decrease of the net-cooling rate $\gamma_C$. In particular, the optimal cooling performance is observed for $\kappa_c/\omega_m \approx 0.1 \sim 0.3$, and that the cooling performance of the assisted case is better than that of the unassisted case (i.e., $n_{f,\text{assisted}} < n_{f,\text{unassisted}}$). When $\kappa_c/\omega_m < 0.1$, the cooling performance becomes worse with the decrease of $\kappa_c$, because the net-cooling rate $\gamma_C \rightarrow 0$ when $\kappa_c/\omega_m \rightarrow 0$ [101]. Physically, the thermal excitations stored in the mechanical resonator are mainly first transferred to the cavity and then leak from the cavity through the bath coupled to the cavity. When $\kappa_c/\omega_m \rightarrow 0$, the thermal energy leakage from the cavity is too weak and one could not obtain a strong cooling. These findings provide a method to develop the cooling performance of the mechanical resonator by appropriately designing a auxiliary device.

V. ACA QUANTUM ENTANGLEMENT AND ITS NOISE-TOLERANT ABILITY

Now we study the effect of the ACA cooling mechanism on quantum entanglement and its robustness against thermal noises by calculating the logarithmic negativity.
defined by the matrix elements and the drive power \( P_r \) of the auxiliary cavity. Other parameters are the same as those used in Fig. 1.

### A. Logarithmic negativity and minimum residual contangle

Let us define the quadrature fluctuations with \( \delta X_o = (\delta \alpha^+ + \delta \alpha)/\sqrt{2} \) and \( \delta Y_o = i(\delta \alpha^+ - \delta \alpha)/\sqrt{2} \) for \( o \in \{a, a_1, a_2, a_4, \ldots \} \), and the corresponding Hermitian input noise operators with \( \delta X_m^o = (c_m^i + o_m)/\sqrt{2} \) and \( \delta Y_m^o = i(c_m^i - o_m)/\sqrt{2} \). Then, the linearized equations of fluctuations can be written as

\[
\dot{\mathbf{u}}(t) = \mathbf{A}\mathbf{u}(t) + \mathbf{N}(t), \tag{28}
\]

where \( \mathbf{u}(t) = [\delta X_a, \delta Y_a, \delta X_{a_1}, \delta Y_{a_1}, \delta q, \delta p]^T \) is the vector of fluctuation operators, \( \mathbf{N}(t) = \left( \sqrt{\kappa}X_{a_1}, \sqrt{\omega_m}X_m, \sqrt{\Delta}\right) \) is the vector of input noises, and the coefficient matrix \( \mathbf{A} \) is given by

\[
\mathbf{A} = \begin{pmatrix}
-\kappa & \Delta & 0 & J & 0 & 0 \\
-\Delta & -\kappa & -J & 0 & \sqrt{\omega_m} & 0 \\
0 & J & -\kappa & \Delta & 0 & 0 \\
-J & 0 & -\Delta & -\kappa & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \omega_m \\
\sqrt{\gamma} & 0 & 0 & 0 & 0 & -\gamma-m
\end{pmatrix}. \tag{29}
\]

The formal solution of Eq. (28) is

\[
\mathbf{u}(t) = \mathbf{M}(t)\mathbf{u}(0) + \int_0^t \mathbf{M}(t-\delta)\mathbf{N}(\delta)\,d\delta, \tag{30}
\]

where \( \mathbf{M}(t) = \exp(\mathbf{A}t) \). Now we calculate the steady-state value of the covariance matrix \( \tilde{\mathbf{V}} \), which is defined by the matrix elements \( \tilde{V}_{kl} = \frac{1}{2}[(\mathbf{u}_k(\infty)\bar{\mathbf{u}}_l(\infty)) + (\mathbf{u}_l(\infty)\bar{\mathbf{u}}_k(\infty))] \), for \( k, l = 1-6 \). Under the stability condition, the covariance matrix \( \tilde{\mathbf{V}} \) fulfills the Lyapunov equation \( \tilde{\mathbf{V}} = \mathbf{AV} + \mathbf{VA}^T = -\mathbf{Q} \), where \( \mathbf{Q} = \text{diag}(\kappa, \kappa, \kappa, \kappa, 0, \omega_m(2\gamma + 1)) \). To study the bipartite entanglement of the system, we adopt quantitative measures of the logarithmic negativity \( E_N \), defined as [103–105]

\[
E_N = \max[0, -\ln(2\zeta^-)], \tag{31}
\]

where \( \zeta^- \equiv 2^{-1/2}\Sigma(\bar{\mathbf{V}}) - [\Sigma(\bar{\mathbf{V}})^2 - 4\text{det}^2(\bar{\mathbf{V}})]^{1/2} \), with \( \Sigma(\bar{\mathbf{V}}) \equiv \text{det}A + \text{det}B - 2\text{det}C \). Here the matrix \( \bar{\mathbf{V}} \) is written as

\[
\bar{\mathbf{V}} = \begin{pmatrix}
\mathcal{A} & \mathcal{C} \\
\mathcal{C}^T & \mathcal{B}
\end{pmatrix}, \tag{32}
\]

where \( \mathcal{A}, \mathcal{B}, \text{and } \mathcal{C} \) are \( 2 \times 2 \) subblock matrices of \( \bar{\mathbf{V}} \).

For studying the tripartite entanglement of the system, we first apply a quantitative measure of the residual contangle \( E_f^{\text{res}} \) [106–108], which is given by

\[
E_f^{\text{res}} = E_f^{s,t} - E_f^{s} - E_f^{t}, \quad (r, s, t = d_1, d_2, e), \tag{33}
\]

where \( E_f^{uv} \) denotes the contangle of subsystems \( u \) (\( u \) contains only one mode) and \( v \) (\( v \) contains one or two modes). \( E_f^{\text{res}} \) is a proper entanglement monotone and it can be
defined as the squared logarithmic negativity [106–108]. The residual contangle satisfies the monogamy property of quantum entanglement, \( E_{\tau}^{(st)} \geq 0 \), i.e.,
\[
E_{\tau}^{(st)} \geq E_{\tau}^{(ar)} + E_{\tau}^{(rb)}. \tag{33}
\]
This inequality is analogous to the popular Coffman-Kundu-Wootters monogamy inequality, which holds for three qubits [107].

A bona fide quantification of continuous-variable tripartite entanglement is provided by the minimum residual contangle [106–108]
\[
E_{\tau}^{(rst)} \equiv \min_{(r,s,t)} [E_{\tau}^{(rst)} - E_{\tau}^{(ar)} - E_{\tau}^{(rb)}], \tag{34}
\]
where \((r,s,t) = (d_1, d_2, c)\) denotes all the permutations of the three mode indexes [106]. The nonzero minimum residual contangle \( E_{\tau}^{(rst)} > 0 \) means that the genuine tripartite entanglement is generated.

**B. ACA bipartite entanglements**

To study quantum entanglement properties of this system, the foremost task is to find the optimal detuning \( \Delta_a \) and decay rate \( \kappa_a \) of the pumped auxiliary cavity. In Figs. 7(a), 7(b), and 7(c), we present a quantum entanglement measure, i.e., the logarithmic negativity, versus the driving detuning \( \Delta_a \) and decay rate \( \kappa_a \): \( E_{a,b} \), \( E_{a,c} \), and \( E_{a,c,a} \) are the auxiliary-cavity-phonon, cooling-cavity-phonon, and photon-photon entanglements, respectively. Note that all the parameters satisfy the stability conditions, which are derived from the Routh-Hurwitz criterion, i.e., the real parts of all the eigenvalues of \( A \) are negative. We can see from Figs. 7(a) and 7(c) that, for the red-detuned driving of the auxiliary cavity, i.e., \( \Delta_a > 0 \), there is no quantum entanglement between the auxiliary cavity and the mechanical resonator (the optomechanical cavity), i.e., \( E_{a,b} = 0 \) \( (E_{a,c,a} = 0) \). In contrast to this, they become strongly entangled for the blue-detuned case, i.e., \( \Delta_a < 0 \), and the highest quantum entanglement can be achieved for \( \Delta_a/\omega_m \approx -1 \).

Physically, the combined effect of the optomechanical and tunneling couplings leads to strong entanglement between the indirectly coupled cavity photons and phonons. We also find that the optomechanical entanglement \( E_{a,b} \) can be greatly enhanced for the blue-detuned driving of the auxiliary cavity but suppressed for the red-detuned case, and that the maximum entanglement is generated at \( \Delta_a/\omega_m \approx 0 \).

In particular, the complementary distribution of the entanglement in Figs. 7(b) and 7(a), 7(c) indicates that the initial cooling-cavity-phonon entanglement is partially transferred to the auxiliary-cavity-phonon and photon-photon subsystems. This effect is prominent when the auxiliary-cavity detuning \( \Delta_a/\omega_m \approx -1 \). In additional, Fig. 7 shows that the entanglement is higher for a smaller decay rate \( \kappa_a \) of the auxiliary cavity.
Because the above enhancement of the entanglement results from the ACA mechanism, it is natural to ask the question whether we can further explore the quantum entanglement by tuning the parameters of the ACA mechanism. To further elucidate this aspect, we plot the logarithmic negativities $E_{a,b}$, $E_{a,b}$, and $E_{a,c}$ as functions of the tunneling coupling $J$ and the pump power $P_R$ of the auxiliary cavity, as shown in Figs. 7(d), 7(e), and 7(f), respectively. We find that, by using the ACA mechanism, both photon-phonon and photon-photon entanglement are generated, and the photon-phonon entanglement is much larger than photon-photon entanglement, i.e., $E_{a,b}$, $E_{a,b} > E_{a,c}$. The highest entanglement $E_{a,b}$ and $E_{a,c}$ is observed for: $0.3 \leq J/\omega_m \leq 0.6$ and $45 \leq P_R$ mW, and $E_{a,b}$ is observed for: $0.15 \leq J/\omega_m \leq 0.3$ and $50 \leq P_R$ mW. This offers a new method to generate and enhance fragile quantum resources by utilizing auxiliary devices.

C. ACA noise-tolerant ability

Thermal noises in practical devices can destroy fragile quantum resources. To protect quantum resources from environmental thermal perturbations, we introduce the ACA mechanism, which can significantly improve the robustness of quantum entanglement against thermal noises.

When the system works in both auxiliary-cavity-unassisted (the green solid line) and -assisted (marked by green symbols) cases, we plot the logarithmic negativities $E_{a,b}$ and $E_{a,c}$ as a function of the thermal excitation number $\bar{n}$ of the mechanical resonator, as shown in Fig. 8. We find that the optomechanical entanglement $E_{a,b}$ is greatly improved by the ACA method, and its robustness against thermal noises is much stronger than that of the unassisted case. For example, when we switch the auxiliary-cavity-unassisted to -assisted cases, $E_{a,b}$ can be increased from $E_{a,b} \approx 0.07$ to $E_{a,b} \approx 0.17$ when $\bar{n} = 0$. This means that the ACA mechanism can significantly enhance the optomechanical entanglement.

In addition, we can see from Fig. 8 that, in the unassisted case, quantum entanglement only emerges when $\bar{n} \approx 200$ (see the green solid line), while in the assisted case, it can persist for thermal phonons near $\bar{n} = 900$ (see the green symbols), which means that the noise robustness in the ACA case is 4.5 times greater than that in the unassisted case. This indicates that the ACA mechanism provides a feasible method to protect fragile quantum resources from environmental thermal perturbations in practical devices, and to build noise-tolerant quantum processors. Moreover, we find that due to the combined effect of the optomechanical and tunneling couplings, the indirectly coupled cavity photons and phonons can be entangled strongly ($E_{a,b}$, marked by blue symbols), and the robustness of quantum entanglement against noise is even up to three times that of the directly coupled case, as shown in Fig. 8. In particular, owing to the tunneling coupling between the cooling and auxiliary cavities, the cooling-cavity photons and auxiliary-cavity photons can be entangled, and this entanglement is strongly robust against thermal noise ($E_{a,c}$, marked by the red symbols). These findings provide a useful strategy to improve the performance of fragile quantum resources by just utilizing auxiliary devices.

D. Tripartite entanglement

Besides bipartite entanglements, the application of the ACA mechanism can lead to a genuinely tripartite entanglement, as demonstrated by the nonzero minimum residual contangle in Eq. (34). In Fig. 9, we plot the tripartite entanglement, quantified by the minimum residual contangle $E^{\text{res}}_{\tau}$, versus the scaled effective driving detuning $\Delta_a/\omega_m$ when $J = 0$ (see the horizontal black solid line), $J/\omega_m = 0.15$ and $P_R = 0$ (blue solid curve), and $J/\omega_m = 0.15$ and $P_R = 50$ mW (red dashed curve). We find that, without the ACA mechanism (i.e., $J = 0$), no tripartite entanglement is generated (i.e., $E^{\text{res}}_{\tau} = 0$, see the horizontal black solid line); while with the ACA mechanism (i.e., $J/\omega_m = 0.15$), strong tripartite entanglement is generated (i.e., $E^{\text{res}}_{\tau} > 0$, see the blue or red curves). In particular, the tripartite entanglement in $P_R \neq 0$ case (see the red dashed curve) is much stronger than that when in $P_R = 0$ case (see the blue solid curve). Very recently, the tripartite entanglement has been achieved in a cavity magnomechanical system, which consists of cavity microwave photons, magnons, and phonons [108–110].

Finally, we remark that in experiments, quantum entanglement can be detected by measuring the covariance matrix $\tilde{\mathbf{V}}$ under a proper readout choice via a filter [111–113]. The optical quadratures can be measured via the homodyne or heterodyne detection of the output [113–115], and the readout of mechanical quadratures requires a probe being resonant with the anti-Stokes sideband, mapping the mechanical motion to the output field [113].
VI. CONCLUSION

In conclusion, we have shown how to achieve a giant amplification in the net cooling rate of a mechanical resonator, and to realize significantly enhanced optomechanical refrigeration and entanglement in an auxiliary-cavity-assisted optomechanical system. We have demonstrated that the genuine tripartite entanglement of cooling-cavity photons, auxiliary-cavity photons, and phonons can be generated by using the ACA method. Specifically, we have revealed that the tripartite entanglement arises from the ACA mechanism, without which it vanishes. We also found that the blue-detuned driving of the auxiliary cavity leads to an enhanced cooling and entanglement, while the red-detuned driving suppresses them.

More importantly, we have revealed that the ACA entanglement has a much stronger robustness against thermal noises in comparison with the auxiliary-cavity-unassisted case. Our work could potentially be used for further manipulating and observing quantum mechanical effects, protecting fragile quantum resources from environmental thermal noises, and building noise-tolerant quantum processors.

Appendix A: Analytical expressions of the steady-state mean phonon number

In this Appendix, we show the exact analytical expressions of the steady-state average phonon numbers in the mechanical resonator. As shown in Sec. III B, by calculating the integral in Eq. (7) for the position and momentum fluctuation spectra, the exact steady-state mean phonon number can be obtained in the form [35, 51]

\[
n_f = \frac{1}{2} \left( \frac{iD_6}{2\Delta_6} + \frac{iM_6}{2\Delta_6} - 1 \right).
\]  

(A1)

Here, we introduce the variables

\[
\Delta_6 = a_3\{a_4(-a_1a_2a_3 + a_2^2 + a_4^2) + [-a_2a_3 + a_1(a_2^2 - 2a_4)]a_5 + a_5^2\} \\
-\{a_1a_3(a_2a_3 + 3a_5) + a_1^2(a_3a_4 + 2a_2a_5)\}a_6 + a_1^2a_6^2,
\]  

(A2)

\[
D_6 = [-a_3a_4a_5 + a_2^2a_6 + a_3(a_2a_5 - a_1a_6)]b_1 + (a_1a_4a_5 - a_5^2 - a_1a_3a_6)b_2 \\
+(-a_1a_2a_5 + a_2a_3 + a_1^2a_6)b_3 + \{ -a_5^2 - a_1^2a_4 + a_1(a_2a_3 + a_5)\}b_4 \\
+\frac{1}{a_6}([-a_3a_4 - a_2a_3a_5 + a_5^2 + a_1^2(a_5^2 - 2a_2a_6) + a_1(-a_2a_3a_4 + a_2^2a_5 - 2a_4a_5 + a_3a_6)]b_5,
\]  

(A3)
and

\[
M_0 = \frac{1}{\omega_m^2} \left\{ -a_5 \left( -a_2 a_3 a_4 + a_2^2 a_5 + a_3 (a_1 a_4 - a_0 a_5) \right) + \left( -a_1 a_3 a_4 + a_0 a_3 a_5 + a_2 (a_3^2 - 2 a_1 a_5) \right) a_6 + a_2^2 a_5 a_6 \right\} + b_1
+ \left[ -a_2 a_3 a_5 + a_2^2 a_6 + a_3 (a_2 a_5 - a_1 a_6) \right] b_2 + (a_1 a_4 a_5 - a_2^2 - a_1 a_3 a_6) b_3
+ (-a_1 a_2 a_5 + a_3 a_5 + a_6^2 a_6) b_4 + \left[ -a_2^2 - a_1^2 a_4 + a_1 (a_2 a_3 + a_5) \right] b_5, \tag{A4}
\]

where the coefficients are defined by:

\[
\begin{align*}
a_0 &= 1, \\
a_1 &= -i (2 \kappa_e + \kappa_a) + \gamma_m, \\
a_2 &= -2 J^2 - 2 \kappa_e (2 \kappa_a + \gamma_m) - \kappa_a (\kappa_a + 2 \gamma_m) - g_c - (\kappa_e^2 + \Delta_a^2), \\
a_3 &= \left( \kappa_e^2 + 2 J^2 (\kappa_e + \kappa_a + \gamma_m) + \kappa_a^2 (2 \kappa_a + \gamma_m) + 2 \kappa_a g_c \\
&\quad + \gamma_m (\Delta_e^2 + \Delta_b^2) + 2 \kappa_e (2 \kappa_a \gamma_m + \omega_m^2 + f_a^2) \right) \\
a_4 &= J^4 - 2 |G_c|^2 \omega_m \Delta + (2 \kappa_e \gamma_m + \omega_m^2) \Delta_e^2 + f_a^2 g_c + 2 J^2 [\kappa_e \gamma_m + \kappa_e (\kappa_a + \gamma_m) + \omega_m^2 - \Delta_a] \\
&\quad + \kappa_e^2 \kappa_a^2 + 2 \kappa_e \gamma_m + g_c + 2 \kappa_c (\gamma_m + f_a^2) + 2 \kappa_e \omega_m^2, \\
a_5 &= i [-J^4 \gamma_m + \kappa_e \left( -\kappa_e \kappa_a \gamma_m - 2 (\kappa_e + \kappa_a) \omega_m^2 \right) + 4 |G_c|^2 \omega_m \Delta - (\kappa_e \gamma_m + 2 \omega_m^2) \Delta_e^2] \\
&\quad - (2 \kappa_e \omega_m^2 + \gamma_m f_a^2) \Delta_b^2 - 2 J^2 [\kappa_e \omega_m^2 + \kappa_e (\kappa_a \gamma_m + \omega_m^2) - \gamma_m \Delta_a] \\
a_6 &= -\omega_m [J^4 \omega_m + 2 J^2 (\kappa_e \kappa_a \omega_m + |G_c|^2 \Delta_a - \omega_m \Delta_a) - [2 |G_c|^2 \Delta + \omega_m f_a^2] f_a^2], \tag{A5}
\end{align*}
\]

and

\[
\begin{align*}
b_0 &= 0, \\
b_1 &= \gamma_m \omega_m^2 (1 + 2 \tilde{n}), \\
b_2 &= 2 \omega_m^2 |G_c|^2 [\kappa_e^2 (1 + 2 \tilde{n}) \gamma_m (2 J^2 - f_e^2 - f_a^2)], \\
b_3 &= \omega_m^2 [2 |G_c|^2 [J^2 (2 \kappa_a + \kappa_e) + \kappa_a (f_e^2 + 2 f_a^2)] + (1 + 2 \tilde{n}) \gamma_m (6 J^4 - 4 \Delta_e^2 f_e^2 + f_e^4 + f_a^4 \\
&\quad + 4 \kappa_e^2 f_a^2 + 4 J^2 (\kappa_e \kappa_a - \Delta_a) - f_e^2 - f_a^2)]], \\
b_4 &= 2 \omega_m^2 \left\{ -2 J^2 [\kappa_e \kappa_a + \kappa_a^2 + \kappa_a (\kappa_e + \kappa_a)] \Delta_e^2 + (4 \kappa_e \kappa_a + \kappa_a^2 + f_e^2) \Delta_a \\
&\quad + (\kappa_e \kappa_a + f_e^2 + \Delta_a) \Delta_b^2 \right\} - \kappa_e^2 (2 \Delta_e^2 f_e^2 + f_a^2 - \Delta_e \Delta_b^2) + 2 J^2 \left\{ \kappa_e^2 \kappa_a + \kappa_a (\Delta_e^2 + \Delta_e \Delta_b^2) + f_a^2 \right\}, \\
b_5 &= \omega_m^2 [J^4 + 2 J^2 (\kappa_e \kappa_a - \Delta_a) + f_e^2 f_a^2 + \left\{ [2 |G_c|^2 (\kappa_e \kappa_a + f_e^2)] + (1 + 2 \tilde{n}) \gamma_m (J^4 + 2 J^2 (\kappa_e \kappa_a - \Delta_a) + f_e^2 f_a^2) \right\}], \tag{A6}
\end{align*}
\]

where

\[
g_c = \omega_m^2 + \Delta_e^2, \quad g_a = \omega_m^2 + \Delta_a^2, \quad f_e^2 = \kappa_e^2 \pm \Delta_e^2, \quad f_a^2 = \kappa_a^2 \pm \Delta_a^2. \tag{A7}
\]

**Appendix B: Bistability analysis**

Equations can be written as

\[
\begin{align*}
\frac{d}{dt} \langle a_e \rangle &= - [\kappa_e + i (\Delta_e - g_0 \langle q \rangle)] \langle a_e \rangle - i \Omega_e - i J \langle a_i \rangle, \\
\frac{d}{dt} \langle a_i \rangle &= - (\kappa_a + i \Delta_a) \langle a_i \rangle - i J \langle a_e \rangle - i \Omega_R, \\
\frac{d}{dt} \langle p \rangle &= -\omega_m \langle q \rangle + g_0 \langle a_e \rangle \langle a_e \rangle - \gamma_m \langle p \rangle, \\
\frac{d}{dt} \langle q \rangle &= \omega_m \langle p \rangle. \tag{B1}
\end{align*}
\]

By separating the degrees of classical motion from the quantum fluctuations in Eq. (3), the classical-motion equations can be written as

The steady-state mean values of the dynamical variables
FIG. 10. The steady-state average displacement \( \langle x \rangle_{ss} \) of the mechanical resonator as a function of the left optical power \( P_L \). The green dashed curve indicates the unstable solutions. Here we set \( \Delta_c = \omega_m \) and \( \Delta_a = -\omega_m \). Other parameters are the same as those used in Fig. 1.

In Fig. 10, we plot the steady-state average displacement \( \langle x \rangle_{ss} \) of the mechanical resonator as a function of the left optical power \( P_L \). One can see that the steady-state average displacement \( \langle x \rangle_{ss} \) varies with the driving power \( P_L \) of the left driving field by solving Eqs. (B2) numerically. It is shown that when \( P_L < 35 \text{ mW} \), only one solution of \( \langle x \rangle_{ss} \) exists and the system is not bistable. When \( 35 < P_L < 150 \text{ mW} \), three solutions of \( \langle x \rangle_{ss} \) exist and the green dashed curve corresponds to the unstable solutions. So the system exhibits bistability in this case. To obtain the cooling and entanglement, a single solution region should be chosen, and we set \( P_L < 35 \text{ mW} \) throughout this work.

\[
\begin{align*}
\langle a_c \rangle_{ss} &= \frac{i(\Omega_L + J\langle a_a \rangle_{ss})}{-(\kappa_c + i\Delta_c)}, \\
\langle a_a \rangle_{ss} &= \frac{i(\Omega_R + J\langle a_c \rangle_{ss})}{-(\kappa_a + i\Delta_a)}, \\
\langle p \rangle_{ss} &= 0, \\
\langle q \rangle_{ss} &= \frac{g_0 \langle a_c \rangle_{ss}^* \langle a_c \rangle_{ss}}{\omega_m}, \\
\langle x \rangle_{ss} &= \frac{\langle q \rangle_{ss}}{\sqrt{m\omega_m}}, \\
\Delta &= \Delta_c - g_0 \langle q \rangle_{ss}, \\
\Delta_a &= \omega_a - \omega_R.
\end{align*}
