Introduction

Recent advancements of nanomaterials have been focused on applications in nanomedicine and nanotechnology based on their outstanding chemical and physical properties [1-14]. Among these nanomaterials, metal nanoclusters (NCs) composed of several to hundreds of metal atoms with unique structural and optical characteristics have been extensively demonstrated for the research fields in imaging, detection, and therapy [15-17]. Great efforts have been made to prepare fluorescent metal NCs using various surface ligands, including small molecules, polymers, and biomacromolecules [18]. For example, gold nanoclusters (AuNCs) conjugated with the surface ligand of glucose have been demonstrated as a target-specific fluorescent probe to analyze the glucose metabolism in the glucose transporter overexpressed brain cancer cells [19]. Fluorescent AuNCs and silver nanoclusters (AgNCs) with surface modification of reactive oxygen species (ROS) scavenger of cysteine have been exploited as a highly biocompatible probe for confocal microscopy [20]. The thiol-modified liquid crystal of 4'-((2-mercaptoethyl)-1,1'-biphenyl)-4-
carbonitrile has been applied as a surface ligand to prepare fluorescent AuNCs [21]. Fluorescent copper nanoclusters (CuNCs) modified with DNA have been utilized for sensitively fluorimetric detection of the mismatch type in a specific DNA sequence for the diagnosis and risk assessment of cancer in the early stage[22]. These metal nanoclusters with different surface modifications, including amino acids, polymers, peptides, antibodies, DNA, and so forth, have revealed outstanding biocompatibility, excellent photostability, and high water solubility for biomedical applications in theranostics.

Various metal NCs have been demonstrated as promising antibacterial agents due to their ultrasmall sizes to increase interaction with bacteria [23-25]. For example, AuNCs conjugated with 6-mercaptophexanoic acid (MHA) have shown higher antibacterial activity in comparison with MHA conjugated gold nanoparticles and the complexes of Au(I)-MHA against Gram-negative Escherichia coli (E. coli) and Gram-positive Staphylococcus aureus (S. aureus) [26]. The amino acid of cysteine-conjugated AuNCs have exhibited antibacterial activity because of the significant increase of intracellular ROS induced by cysteine-conjugated AuNCs in bacteria [27]. The bacitracin-conjugated AuNCs, AgNCs and CuNCs have been validated the antibacterial activities because of the destruction of the bacterial cell wall and the increase of intracellular ROS generation [28]. Real-time observation has demonstrated the antibacterial mechanism between the surface ligand of glutathione conjugated AuNCs and bacteria by in situ liquid cell transmission electron microscopy (TEM) [29]. Although the intensive achievements studies have proven the antibacterial activity of metal NCs, there are only very few studies to demonstrate the cancer therapy using metal NCs.

The investigation of cancer therapy is an urgent task for biomedical applications based on metal nanoclusters. Herein, AuNCs conjugated with the surface ligand of antibody were developed to demonstrate their application in cancer therapy. Carcinoembryonic antigen-related cell adhesion molecule 6 (CEACAM6) is overexpressed in many cancer cells [30]. In this work, a single domain antibody targeting CEACAM6, 2A3, was utilized as a surface ligand to prepare 2A3 conjugated AuNCs (2A3-AuNCs). Structural and optical properties were characterized by TEM, ultraviolet-visible (UV-Vis) spectroscopy, and fluorescence spectroscopy. The cytotoxicities of 2A3-AuNCs incubated with Vero, MDA-MB-231, and MDA-MB-468 cells were respectively examined by resazurin dye reduction assay. To investigate the death of cells, 2A3-AuNCs incubated with Vero, MDA-MB-231, and MDA-MB-468 cells were separately measured by fluorescence images.

**Methods**

**Preparation of 2A3 conjugated gold nanoclusters**

The 2A3 antibody was synthesized according to previous literature [30]. In this work, 2A3-AuNCs were synthesized by a facile hydrothermal approach. For preparing 2A3-AuNCs, 1 mL of HAuCl₄ aqueous solution was first added to a sample vial. Then 2 mL of 2A3 antibody solution was added to the sample vial with HAuCl₄ aqueous solution under vigorous stirring. Afterward, 3 mµL of 1 mM NaOH aqueous solution was added to the sample vial. After stirring for one week in the dark, the solution containing 2A3-AuNCs was obtained. For purifying step, the solution of 2A3-AuNCs was centrifuged at 15000 rpm at 4 °C for 10 min. The supernatant solution containing 2A3-AuNCs was then stored at 4 °C for the following experiments.

**Cell viability assay of 2A3-AuNCs**

Kidney epithelial Vero cells, breast cancer MDA-MB-231 cells, and breast cancer MDA-MB-468 cells were cultured in Dulbecco’s modified Eagle medium (DMEM) with 10% (v/v) fetal bovine serum (FBS). For cell culture, Vero, MDA-MB-231, and MDA-MB-468 cells were cultured in 96-well plates for 24 h and then washed twice with a phosphate-buffered saline (PBS) solution. Afterward, Vero, MDA-MB-231, and MDA-MB-468 cells in 96-well plates were respectively incubated with 2A3-AuNC solutions (270, 135, 67.5, 33.75, 16.88, 8.44, 4.22, 2.11, and 1.05 μg/mL). The sterilized water was used for the control experiments. The
Inhibition of cancer cells using target-specific 2A3 antibody-conjugated gold nanoclusters

Cell viabilities of Vero, MDA-MB-231, and MDA-MB-468 cells incubated with 2A3-AuNCs were measured by resazurin dye reduction assay. After incubating 2A3-AuNCs with Vero, MDA-MB-231, and MDA-MB-468 cells for 24 h, the resazurin (final concentration of 0.02 mg/mL) was added to each well of the 96-well plates and then incubated for 4 h. The absorbances at 570 and 600 nm were measured by a plate reader. The cell viability assay was replicated eight times for each cell line.

Analysis of cell death by fluorescence imaging

SYTOX green nucleic acid stain was applied to stain dead cells by fluorescence imaging. Herein, SYTOX green nucleic acid stain (5 μM) was added to cells and then the cells, and SYTOX green nucleic acid stain were incubated in a shaker at 200 rpm and 37 °C for 15 min in the dark. Afterward, the solution of SYTOX green nucleic acid stain was carefully removed and the cells were further washed by medium for three times. Sequentially, Hoechst 33342 nucleic acid stain (1 μg/mL) was added to stain total cells. After incubation of cells and Hoechst 33342 nucleic acid stain in a shaker at 200 rpm and 37 °C for 10 min in dark, the solution of Hoechst 33342 nucleic acid stain was carefully removed and the cells were further washed by medium for three times. The cells stained by SYTOX green nucleic acid stain and Hoechst 33342 nucleic acid stain were observed using microscope (Leica DM1000). To obtain better image contrast, we assigned a false green for the fluorescence of SYTOX stain channel and a false blue for the Hoechst 33342 stain channel.

Results

Structural characterizations of 2A3-AuNCs

TEM (Hitachi HT-7700) was applied to examine the shape of 2A3-AuNCs. As shown in the TEM image of Figure 1a, the shape of 2A3-AuNCs exhibited a roughly spherical shape. Furthermore, a histogram was systematically calculated the size distribution of 2A3-AuNCs based on 100 nanoclusters in the TEM image of Figure 1a as shown in Figure 1b. A Gaussian fitting curve of Figure 1b was simulated, and the result of the Gaussian fitting curve indicated that the average size of 2A3-AuNCs was calculated to be 2.35 nm.

Optical properties of 2A3-AuNCs

UV-Vis absorption spectrometer (Jasco V-770) and fluorescence spectrometer (Jasco FP-8500) were applied to further examine optical properties to characterize 2A3-AuNCs. As shown in Figure 2a, the absorption spectrum of 2A3-AuNCs showed no surface plasmon absorption. The disappearance of the surface plasmon absorption of 2A3-AuNCs can be attributed to that 2A3-AuNCs exhibited high gold oxidation states to result in a lack of free electrons for the generation of coherent

Inhibition of cancer cells using target-specific 2A3 antibody-conjugated gold nanoclusters

Oscillations [31]. Moreover, the fluorescence spectrum of 2A3-AuNCs revealed a maximum fluorescence intensity at 350 nm, as shown in Figure 2b. The fluorescence quantum yield of 2A3-AuNCs was 4.0% by integrating the sphere (Jasco ILF-835). The fluorescence of 2A3-AuNCs can be ascribed to the fluorescent mechanism of aggregation-induced emission (AIE). Several reports have proven that the AIE fluorescence of AuNCs is caused by the aggregation of Au(I) and ligand on the surface of AuNCs [32-34]. Overall, structural and optical characterizations of 2A3-AuNCs confirmed that the facile hydrothermal approach successfully synthesized fluorescent 2A3-AuNCs.

Cell viability of 2A3-AuNCs

To examine the potential for cancer therapy, the cell viabilities of 2A3-AuNCs were respectively evaluated in Vero, MDA-MB-231, and MDA-MB-468 cells. The water-soluble 2A3-AuNCs with different concentrations (270, 135, 67.5, 33.75, 16.88, 8.44, 4.22, 2.11, and 1.05 μg/mL) were prepared to investigate their cytotoxicities. As shown in Figure 3, the resazurin dye reduction assay revealed high cell viabilities (>80%) for 2A3-AuNCs. However, for MDA-MB-231 and MDA-MB-468 cells with overexpressed CEACAM6, the cell viabilities decreased with the concentration of 2A3-AuNCs. The results of cell viabilities of 2A3-AuNCs indicated that antibody of 2A3 on the

The surface of 2A3-AuNCs could target onto CEACAM6 overexpressed MDA-MB-231 and MDA-MB-468 cells and then inhibit the growth of MDA-MB-231 and MDA-MB-468 cells.

Investigation of cell death induced by 2A3-AuNCs

To investigate the cell death, fluorescence images of cells including Vero, MDA-MB-231, and MDA-MB-468 cells were respectively examined after incubation with 2A3-AuNCs for 120 min. As shown in fluorescence images of Figure 4, the total numbers of Vero, MDA-MB-231, and MDA-MB-468 cells revealed no significant difference. Moreover, after incubation with 2A3-AuNCs, no significant death of Vero cells was observed in the fluorescence image. However, for MDA-MB-231 and MDA-MB-468 cells, drastic cell deaths were observed after incubation with 2A3-AuNCs. The results of fluorescence images indicated that the ligand of 2A3 on the surface of 2A3-AuNCs could inhibit the growths of cancer cells with CEACAM6 overexpressed MDA-MB-231 and MDA-MB-468 cells.

Discussion

The treatment of cancer is an urgent issue for biomedical applications based on metal nanoclusters. Herein, the 2A3-AuNCs were synthesized to inhibit cancer cells by the facile hydrothermal approach. The structural and optical properties of 2A3-AuNCs confirmed the successful preparation of fluorescent 2A3-AuNCs with the roughly spherical shape and the size of 2.35 nm by the facile hydrothermal approach. The cell viability assay demonstrated that 2A3-AuNCs could inhibit the growths of cancer cells, including MDA-MB-231 and MDA-MB-468 breast cells. The fluorescence images also indicated that 2A3-AuNCs could inhibit the growths of cancer cells.

Figure 4. Cell death assay of 2A3-AuNCs. Fluorescence images of 2A3-AuNCs incubated with Vero, MDA-MB-231, and MDA-MB-468 cells for 120 min. The blue and green pseudocolors represent the fluorescent signals of total cells (stained with Hoechst 33342) and dead cells (stained with SYTOX green), respectively. The scale bars were 1 mm.
cancer cells of MDA-MB-231 and MDA-MB-468 breast cells. Based on the similar results of cell viability assay and fluorescence imaging, the surface ligand of 2A3 antibody on 2A3-AuNCs exhibited significant inhibition of cancer cells with CEACAM6 overexpressed, including MDA-MB-231 and MDA-MB-468 breast cells. For further clinical application, the in vivo studies of 2A3-AuNCs are still needed in the future.

Conclusion

In conclusion, fluorescent 2A3-AuNCs were successfully prepared by the facile hydrothermal approach. The optical and structural characterizations of 2A3-AuNCs were demonstrated by TEM image and UV-Vis spectrum. The results of the cell viability assay confirmed that 2A3-AuNCs revealed cancer cell inhibition for CEACAM6 overexpressed MDA-MB-231 and MDA-MB-468 cells. The results of fluorescence imaging also indicated that the 2A3 antibody on the surface of 2A3-AuNCs showed significant cancer cell inhibition for CEACAM6 overexpressed MDA-MB-231 and MDA-MB-468 cells. Overall, our studies showed that 2A3-AuNCs could be a promising fluorescent probe for the detection and therapy in the cancer cell.

Acknowledgment

We would like to thank Dr. Chi-Ming Lee and Chun-Chih Liu for their help with materials characterizations at the TMU Core Facility Center.

Funding

We acknowledge the Ministry of Science and Technology, Taiwan (grant no.: MOST 109-2113-M-038-005-MY2) and the Taipei Medical University for financially supporting this work.

Author contributions

JCK and DIK performed the experiment, DIK and TRK wrote the manuscript, JCK, DIK, S, FR, ES and TRK conceptualize, develop the methodology, and provided expertise and feedback.

Declaration of interest

The authors do not have any conflict of interest.
