Moduli for Pairs of Elliptic Curves with Isomorphic $N$-torsion

David Carlton

February 2, 2022

Abstract

We study the moduli surface for pairs of elliptic curves together with an isomorphism between their $N$-torsion groups. The Weil pairing gives a “determinant” map from this moduli surface to $(\mathbb{Z}/N\mathbb{Z})^*$; its fibers are the components of the surface. We define spaces of modular forms on these components and Hecke correspondences between them, and study how those spaces of modular forms behave as modules for the Hecke algebra. We discover that the component with determinant $-1$ is somehow the “dominant” one; we characterize the difference between its spaces of modular forms and the spaces of modular forms on the other components using forms with complex multiplication. Finally, we show some simplifications that arise when $N$ is prime, including a complete determination of such CM-forms, and give numerical examples.

1 Introduction

If $R$ is the ring of integers in a totally real number field, one can consider the Hilbert modular variety associated to $R$, which parameterizes abelian varieties of dimension $[R : \mathbb{Z}]$ together with a map from $R$ into their endomorphism ring. This modular variety is disconnected; its components
correspond to polarization types, and are indexed by elements of the narrow class group of \( R \). One can define spaces of modular forms associated to the modular variety and to its components; the former are more adelic in nature, while the latter are more classical.

In this paper, we consider a variant of the above situation, where we replace \( R \) by the order \((\mathbb{Z} \times \mathbb{Z})_{\equiv N}\) that consists of pairs of integers that are congruent mod \( N \). Thus, we replace our totally real number field by the totally real “number algebra” \( \mathbb{Q} \times \mathbb{Q} \), and in addition consider a non-maximal order rather than the full ring of integers. As in the traditional situation, one can associate a modular variety to this situation, and study its components, which are indexed by \((\mathbb{Z}/N\mathbb{Z})^*\); this has been done in Hermann \( \textsuperscript{[5]} \) and Kani and Schanz \( \textsuperscript{[7]} \). One can also define spaces of classical and adelic modular forms, which we do in this paper.

These “degenerate” Hilbert modular varieties and modular forms should have properties very similar to those of traditional Hilbert modular varieties and modular forms. However, they can also be related to modular curves and elliptic modular forms, which have been the subject of extensive study. For example, these surfaces have an interpretation as moduli spaces for pairs of elliptic curves with isomorphic \( N \)-torsion, and can be constructed as a quotient of \( X(N) \times X(N) \). Thus, we expect them to be a particularly suitable test ground for exploring properties of Hilbert modular surfaces and modular forms. We expect the generalization to the case where \( R \) is an order in a product of ring of integers of totally real number fields to be of interest as well: for example, \( R \) might be the Hecke algebra \( T_0(N) \) associated to the modular curve \( X_0(N) \).

One such new property, which is the main goal of this paper, involves studying how these components of the degenerate Hilbert modular variety vary. It is easy to see that two components whose index differs by a square are isomorphic, but there is no reason why other components should be isomorphic. Indeed, Hermann has shown that, for example, if \( N = 7 \) then the component indexed by 1 is a rational surface and the component indexed by \(-1\) is a K3 surface; similarly, if \( N = 11 \), the component indexed by 1 is an elliptic surface and the component indexed by \(-1\) is of general type. As Kani and Schanz noted, this change in geometric complexity is reflected by the geometric genera of the components.

We show in Section \( \textsuperscript{5} \) that, for \( N \) fixed and prime, the component indexed by \(-1\) always has the largest geometric genus of any of the components; we give an explicit formula for the difference of geometric genera in Section \( \textsuperscript{8} \). The geometric genus of a component is the dimension of a suitable space of cusp forms; we exhibit this difference in genera as the dimension of a certain special subspace of the space of cusp forms on the \(-1\) surface; we call it the Hecke kernel since it can be seen as the intersection of the kernels of certain Hecke operators. We also show in Section \( \textsuperscript{6} \) that the elements of the Hecke kernel have an alternative characterization as forms with complex multiplication; we give an explicit construction of the forms in Section \( \textsuperscript{9} \). The proof of these results involves the interplay between spaces of adelic and classical modular forms.

I would like to thank Fred Diamond, Jordan Ellenberg, Steven Kleiman, and Barry Mazur for the help that they have given me while writing this; and the N.D.S.E.G. Fellowship Program for the support that it has provided.

2 Basic Definitions

Let \( X_0(N) \) be the curve over \( \mathbb{C} \) parameterizing elliptic curves together with a basis for their \( N \)-torsion that maps to some specified \( N \)’th root of unity under the Weil pairing\( \textsuperscript{1} \). It is Galois over

---

\( \textsuperscript{1} \)This curve is traditionally denoted by \( X(N) \); however, we have chosen to use the notation \( X(N) \) to denote the (geometrically reducible) curve coming from the adelic mod \( N \) principal congruence subgroup, and have changed all notation accordingly.
the curve $X_w(1)$ with Galois group $\text{SL}_2(\mathbb{Z}/N\mathbb{Z})/\{\pm 1\}$. Let $\text{SL}_2(\mathbb{Z}/N\mathbb{Z})$ act on the product surface $X_w(N) \times X_w(N)$ via the diagonal action; we can then form the quotient surface, which we shall denote by $X_{\infty,1}(N)$. More generally, if $\epsilon$ is an element of $(\mathbb{Z}/N\mathbb{Z})^*$ and if $\text{SL}_2(\mathbb{Z}/N\mathbb{Z})$ acts on the first factor via the natural action but on the second factor via the automorphism

$$
\theta_\epsilon: \begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto \begin{pmatrix} a & \epsilon^{-1}b \\ \epsilon c & d \end{pmatrix}
$$

then we denote the quotient surface by $X_{\infty,\epsilon}(N)$. And we set

$$X_{\infty}(N) = \coprod_{\epsilon \in (\mathbb{Z}/N\mathbb{Z})^*} X_{\infty,\epsilon}(N).$$

These surfaces can also be constructed in another fashion, as degenerate Hilbert modular surfaces: let $\mathcal{H}$ be the upper half plane, with $\Gamma(1) = \text{SL}_2(\mathbb{Z})$ acting on it via fractional linear transformations. Then $\Gamma(1) \times \Gamma(1)$ acts on $\mathcal{H} \times \mathcal{H}$; if we denote by $\Gamma_{\infty,\epsilon}(N)$ the subgroup of $\Gamma(1) \times \Gamma(1)$ given by

$$\begin{cases}
\left( \begin{pmatrix} a_1 & b_1 \\ c_1 & d_1 \end{pmatrix}, \begin{pmatrix} a_2 & b_2 \\ c_2 & d_2 \end{pmatrix} \right) \\
\begin{array}{l}
\begin{aligned}
& a_1 \equiv a_2 (\text{mod } N), \\
& b_1 \equiv \epsilon b_2 (\text{mod } N), \\
& c_1 \equiv c_2 (\text{mod } N), \\
& d_1 \equiv d_2 (\text{mod } N)
\end{aligned}
\end{array}
\end{cases}$$

then the quotient $\Gamma_{\infty,\epsilon}(N)\mathcal{H} \times \mathcal{H}$ is an open subset of $X_{\infty,\epsilon}(N)$, and if we denote by $\mathcal{H}^*$ the space $\coprod \mathbb{P}^1(\mathbb{Q})$ then $\Gamma_{\infty,\epsilon}(N) \mathcal{H}^* \times \mathcal{H}^*$ is all of $X_{\infty,\epsilon}(N)$.

The surface $X_{\infty,\epsilon}(N)$ (or, more properly, the open subset given by using $\mathcal{H} \times \mathcal{H}$ instead of $\mathcal{H}^* \times \mathcal{H}^*$) is a coarse moduli space for triples $(E_1, E_2, \phi)$ where the $E_i$'s are elliptic curves and $\phi$ is an isomorphism from $E_1[N]$ to $E_2[N]$ such that $\wedge^2 \phi$ raises the Weil pairing to the $\epsilon$th power. The modular parameterization is given as follows: let $(\tau_1, \tau_2) \in \mathcal{H} \times \mathcal{H}$ and let $E_i$ be the elliptic curve given by the lattice with basis $\{1, \tau_i\}$. Also, let $\epsilon$ be an integer that reduces to $\epsilon$ mod $N$. We then have the map $\phi$ from $E_1[N]$ to $E_2[N]$ that sends $\tau_1/N$ to $\epsilon \tau_2/N$ and $1/N$ to $1/N$; it raises the Weil pairing to the $\epsilon$th power, the group of elements of $\Gamma(1) \times \Gamma(1)$ that preserve $\phi$ is the subgroup $\Gamma_{\infty,\epsilon}(N)$ defined above, and every triple $(E_1, E_2, \phi)$ arises in this fashion.

The structure of the $X_{\infty,\epsilon}(N)$'s as complex surfaces has been studied by Hermann in [3] and by Kani and Schanz in [4]; our $X_{\infty,\epsilon}(N)$ is Hermann’s $Y_{N,\epsilon-1}$ and Kani and Schanz’s $Z_{N,\epsilon-1}$. In particular, Kani and Schanz give explicit formulas and tables computing various invariants of the $X_{\infty,\epsilon}(N)$’s, such as the dimensions of various cohomology groups. They also give explicit minimal desingularizations of the surfaces.

We now define spaces of modular forms on these surfaces. Thus, let $f: \mathcal{H} \times \mathcal{H} \to \mathbb{C}$ be a holomorphic function; let $\gamma = (\gamma_1, \gamma_2)$ be an element of $\text{GL}_2^+(\mathbb{R}) \times \text{GL}_2^+(\mathbb{R})$, where $\text{GL}_2^+(\mathbb{R})$ is the set of elements of $\text{GL}_2(\mathbb{R})$ with positive determinant; and let $k = (k_1, k_2)$ be a pair of natural numbers. We define the function $f|k,\gamma: \mathcal{H} \times \mathcal{H} \to \mathbb{C}$ by

$$f|k,\gamma(z_1, z_2) = f(\gamma_1(z_1), \gamma_2(z_2)) j(\gamma_1, z_1)^{-k_1} j(\gamma_2, z_2)^{-k_2}$$

where, if $\sigma = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is an element of $\text{GL}_2^+(\mathbb{R})$, then $\sigma(z) = (az + b)/(cz + d)$ and

$$j(\sigma, z) = (ad - bc)^{-1/2}(cz + d).$$

We replaced their $\epsilon$ by $\epsilon^{-1}$ to simplify the normalizations given in Section 3 since $X_{\infty,\epsilon}(N)$ and $X_{\infty,\epsilon-1}(N)$ are isomorphic, this is an unimportant change.
We write \( f|_\gamma \) instead of \( f|_{k,\gamma} \) if \( k \) is clear from context.

Defining \( \Gamma(1) \) to be \( \text{SL}_2(\mathbb{Z}) \), we say that a subgroup \( \Gamma \) of \( \Gamma(1) \times \Gamma(1) \) is a \textit{congruence subgroup} if it contains the group \( \Gamma_w(N) \times \Gamma_w(N) \) for some \( N \), where \( \Gamma_w(N) \) is defined to be the set of matrices in \( \text{SL}_2(\mathbb{Z}) \) that are congruent to the identity mod \( N \). A function \( f: \mathfrak{H} \times \mathfrak{H} \to \mathbb{C} \) is a \textit{modular form} for \( \Gamma \) of weight \( k \) if \( f|_{k,\gamma} = f \) for all \( \gamma \in \Gamma \) and if \( f \) is holomorphic at the cusps. To explain this latter condition, assume that \( \Gamma_w(N) \times \Gamma_w(N) \subset \Gamma \). Then \( f(z_1 + N, z_2) = f(z_1, z_2) \) for all \((z_1, z_2) \in \mathfrak{H} \times \mathfrak{H} \); so setting \( q_1 = e^{2\pi i \sqrt{-1} z_1/N} \), we can write

\[
    f(z_1, z_2) = \sum_{m \in \mathbb{Z}} c_m(f)(z_2)q_1^m
\]

for some functions \( c_m(f) \). If \( c_m(f) \) is zero for all \( m < 0 \) and if a similar condition holds if we do a Fourier expansion in \( z_2 \), we say that \( f \) is \textit{holomorphic at infinity}. And \( f \) is \textit{holomorphic at all of the cusps} if, for all \( \gamma \in \Gamma(1) \times \Gamma(1) \), \( f|_{k,\gamma} \) is holomorphic at infinity.

A modular form is a \textit{cusp form} if it vanishes at all of the cusps; that is to say, if whenever we take a Fourier expansion of \( f|_{k,\gamma} \) in either variable as above, \( c_0(f) \) is zero. We denote the space of all modular forms of weight \( k \) for \( \Gamma \) by \( M_k(\Gamma) \); we denote the space of all cusp forms by \( S_k(\Gamma) \).

If \( \Gamma = \Gamma_1 \times \Gamma_2 \), with each \( \Gamma_i \) a congruence subgroup of \( \Gamma(1) \), then there is a natural map from \( M_{k_1}(\Gamma_1) \otimes M_{k_2}(\Gamma_2) \to M_{(k_1,k_2)}(\Gamma_1 \times \Gamma_2) \) which sends \( f_1 \otimes f_2 \) to the function

\[
    (z_1, z_2) \mapsto f_1(z_1)f_2(z_2).
\]

Furthermore, this map sends cusp forms to cusp forms. It is in fact an isomorphism in either the modular form or cusp form case:

Proposition 2.1. If \( S \) is a subset of \( \mathfrak{H}^* \) or \( \mathfrak{H}^* \times \mathfrak{H}^* \) and \( \Gamma \) is a congruence subgroup of \( \Gamma(1) \) or \( \Gamma(1) \times \Gamma(1) \), let \( M_k(\Gamma, S) \) be the set of forms in \( M_k(\Gamma) \) that vanish on the points in \( S \). Then for any congruence subgroups \( \Gamma_1 \) and \( \Gamma_2 \) of \( \Gamma(1) \) and subsets \( S_1 \) and \( S_2 \) of \( \mathfrak{H}^* \), the natural map

\[
    M_{k_1}(\Gamma_1, S_1) \otimes M_{k_2}(\Gamma_2, S_2) \to M_{(k_1,k_2)}((\Gamma_1 \times \Gamma_2), (S_1 \times \mathfrak{H}^*) \cup (\mathfrak{H}^* \times S_2))
\]

is an isomorphism.

Proof. This follows by induction on the dimension of \( M_{k_1}(\Gamma_1, S_1) \).

Corollary 2.2. Given any natural numbers \( k_1, k_2, \) and \( N \), we have isomorphisms

\[
    M_{(k_1,k_2)}((\Gamma_{\infty,\infty}(N)) = (M_{k_1}(\Gamma_w(N)) \otimes M_{k_2}(\Gamma_w(N)))^{\text{SL}_2(\mathbb{Z}/N\mathbb{Z})}
\]

and

\[
    S_{(k_1,k_2)}((\Gamma_{\infty,\infty}(N)) = (S_{k_1}(\Gamma_w(N)) \otimes S_{k_2}(\Gamma_w(N)))^{\text{SL}_2(\mathbb{Z}/N\mathbb{Z})},
\]

where \( \text{SL}_2(\mathbb{Z}/N\mathbb{Z}) \) acts on the first member of the tensor product in the natural fashion and on the second member via the automorphism \( \theta_e \).

Proof. By Proposition 2.1.

\[
    M_{(k_1,k_2)}((\Gamma_w(N) \times \Gamma_w(N)) = (M_{k_1}(\Gamma_w(N)) \otimes M_{k_2}(\Gamma_w(N))); \]

that \( \text{SL}_2(\mathbb{Z}/N\mathbb{Z}) \)-invariants correspond to forms in \( M_{(k_1,k_2)}((\Gamma_{\infty,\infty}(N)) \) follows from the definitions. The cusp form case is similar, setting \( S_1 \) and \( S_2 \) in the Proposition to be equal to \( \mathbb{P}^1(\mathbb{Q}) \).
This allows us to express the dimension of the space \( S_{2,2}(\Gamma_{\mathbb{Z},\epsilon}(N)) \) in terms of data given in Kani and Schanz \[3\]:

**Corollary 2.3.** The dimensions of the spaces \( S_{2,2}(\Gamma_{\mathbb{Z},\epsilon}(N)) \) and \( H^2(X_{\mathbb{Z},\epsilon}(N), \mathcal{O}_{X_{\mathbb{Z},\epsilon}(N)}) \) are equal, and they are also equal to the geometric genus of a desingularization of \( X_{\mathbb{Z},\epsilon}(N) \).

**Proof.** We have the equalities

\[
\dim S_{2,2}(\Gamma_{\mathbb{Z},\epsilon}(N)) = \dim(S_2(X_w(N)) \otimes S_2(X_w(N)))^\text{SL}_2(\mathbb{Z}/N\mathbb{Z})
\]

\[
= \dim(H^1(X_w(N), \mathcal{O}_{X_w(N)}) \otimes H^1(X_w(N), \mathcal{O}_{X_w(N)}))^{\text{SL}_2(\mathbb{Z}/N\mathbb{Z})}
\]

\[
= \dim H^2(X_w(N) \times X_w(N), \mathcal{O}_{X_w(N) \times X_w(N)})^{\text{SL}_2(\mathbb{Z}/N\mathbb{Z})}
\]

\[
= \dim H^2(X_{\mathbb{Z},\epsilon}(N), \mathcal{O}_{X_{\mathbb{Z},\epsilon}(N)}).
\]

This last quantity is equal to the geometric genus, by Kani and Schanz \[6\], Proposition 3.1. \( \square \)

Of course, this isn’t too surprising: weight 2 cusp forms should correspond to holomorphic 2-forms.

If \( f \) is a modular form on \( \Gamma_{\mathbb{Z},\epsilon}(N) \), it has a Fourier expansion

\[
f(z_1, z_2) = \sum_{m_1, m_2 \geq 0} c_{m_1, m_2}(f) q_1^{m_1} q_2^{m_2}
\]

where \( q_\ell = e^{2\pi \sqrt{-1} z_\ell/N} \). There is one thing that we can say immediately about the Fourier coefficients \( c_{m_1, m_2}(f) \):

**Proposition 2.4.** For all \( f \in M_{(k_1, k_2)}(\Gamma_{\mathbb{Z},\epsilon}(N)) \), the Fourier coefficient \( c_{m_1, m_2}(f) \) is zero unless \( \ell m_1 + m_2 \equiv 0 \pmod{N} \).

**Proof.** This follows from the fact that \( f = f(\begin{pmatrix} 1 & \epsilon \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}) \), where \( \epsilon \) is an integer congruent to \( \epsilon \) mod \( N \). \( \square \)

Thus, most of the Fourier coefficients are “missing”. This turns out to make it natural to also study modular forms on the surface \( X_{\mathbb{Z},\epsilon}(N) \), even when we are only interested in one of the individual \( X_{\mathbb{Z},\epsilon}(N) \)'s; we shall elaborate on this theme in Section \[3\].

One way to produce forms on \( X_{\mathbb{Z},\epsilon}(N) \) is to consider forms on \( X_{\mathbb{Z},\epsilon}(N/d) \) to be forms on \( X_{\mathbb{Z},\epsilon}(N) \), for \( d \) a divisor of \( N \). Such forms have Fourier coefficients \( c_{m_1, m_2} \) equal to zero unless \( d \) divides \( m_1 \) (and hence \( m_2 \), by Proposition 2.4). The converse is also true:

**Theorem 2.5.** Let \( f \) be a modular form of weight \( k \) on \( \Gamma_{\mathbb{Z},\epsilon}(N) \), and assume that, for some \( d\mid N \), we have \( c_{m_1, m_2}(f) = 0 \) unless \( d\mid m_1 \). Then \( f \) is an element of \( M_k(\Gamma_{\mathbb{Z},\epsilon}(N/d)) \).

**Proof.** The fact that \( c_{m_1, m_2}(f) = 0 \) unless \( d\mid m_1 \) is equivalent to having \( f \) be invariant under

\[
\begin{pmatrix}
1 & N/d \\
0 & 1
\end{pmatrix},
\begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}
\]

Thus, we have to show that the smallest subgroup \( \Gamma \) containing both \( \begin{pmatrix} 1 & N/d \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \) and \( \Gamma_{\mathbb{Z},\epsilon}(N) \) is \( \Gamma_{\mathbb{Z},\epsilon}(N/d) \). Furthermore, we can take the quotient by \( \Gamma_w(N) \times \Gamma_w(N) \), and thus consider all
matrices to be elements of $\text{SL}_2(\mathbb{Z}/N\mathbb{Z})$. Letting $G = \{ \gamma \in \text{SL}_2(\mathbb{Z}/N\mathbb{Z}) \mid (\gamma, 1) \in \Gamma \}$, we see that $\Gamma = G \times \{1\} \cdot \Gamma_{\infty, \epsilon}(N)$ and that $\Gamma$ is a subgroup if and only if $G$ is normal. Thus, we have to show that the smallest normal subgroup of $\text{SL}_2(\mathbb{Z}/N\mathbb{Z})$ containing the matrix $\tau_{N/d} = \begin{pmatrix} 1/N/d & 0 \\ 0 & 1 \end{pmatrix}$ is the kernel of the natural map from $\text{SL}_2(\mathbb{Z}/N\mathbb{Z})$ to $\text{SL}_2(\mathbb{Z}/(N/d)\mathbb{Z})$. Furthermore, we can assume that $d$ is a prime $p$, and by the Chinese remainder theorem we can assume that $N = p^l$ for some $l$.

First, assume that $l = 1$, so we want to show that the smallest normal subgroup $G$ of $\text{SL}_2(\mathbb{Z}/p\mathbb{Z})$ containing $\tau_1 = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ is the entire group. We first look at the image of $G$ in $\text{PSL}_2(\mathbb{Z}/p\mathbb{Z})$. If $p > 3$ then $\text{PSL}_2(\mathbb{Z}/p\mathbb{Z})$ is simple, so the image of $G$ is all of $\text{PSL}_2(\mathbb{Z}/p\mathbb{Z})$. If $p = 3$ then $\text{PSL}_2(\mathbb{Z}/3\mathbb{Z})$ is isomorphic to $A_4$ and $\tau_1$ is an element of order 3; but since the only proper normal subgroups of $A_4$ contain only elements of order 1 and 2, we again have that the image of $G$ is all of $\text{PSL}_2(\mathbb{Z}/3\mathbb{Z})$.

Similarly, if $p = 2$, then $\text{PSL}_2(\mathbb{Z}/2\mathbb{Z})$ is isomorphic to $S_3$ and $\tau_1$ has order 2, so again our image must be all of $\text{PSL}_2(\mathbb{Z}/2\mathbb{Z})$.

This implies that $G$ must either be all of $\text{SL}_2(\mathbb{Z}/p\mathbb{Z})$ or a subgroup of index two which projects onto all of $\text{PSL}_2(\mathbb{Z}/p\mathbb{Z})$. But if $p = 2$ then $\text{SL}_2(\mathbb{Z}/2\mathbb{Z}) = \text{PSL}_2(\mathbb{Z}/2\mathbb{Z})$; if $p = 3$ then $\text{SL}_2(\mathbb{Z}/3\mathbb{Z})$ has only two non-trivial one-dimensional representations, whose kernels are of index 3; and if $p > 3$ then $\text{SL}_2(\mathbb{Z}/p\mathbb{Z})$ has no non-trivial one-dimensional representations, so again has no subgroups of index 2.

Finally, assume that $l > 1$, and that we have a normal subgroup $G$ containing $\tau_q$, where $q = p^{l-1}$. (Note that $q^3$ is zero in $\mathbb{Z}/p\mathbb{Z}$, which greatly simplifies calculations.) We then have to show that $G$ contains all matrices of the form $\begin{pmatrix} 1+aq & bq \\ cq & 1+dq \end{pmatrix}$ with determinant 1; this condition on the determinant is equivalent to having $a$ equal to $-d$ in $\mathbb{Z}/p\mathbb{Z}$. But it is easy to produce all such matrices by taking suitable multiples of $\tau_q$, its conjugate by $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, and its conjugate by $\begin{pmatrix} a & -1 \\ 1 & a \end{pmatrix}$.

We hope that the following stronger result is true:

**Conjecture 2.6.** Let $f$ be a modular form on $\Gamma_{\infty, \epsilon}(N)$ such that $c_{m_1, m_2}(f) = 0$ unless $(m_1, N) > 1$. Then $f$ can be written as a sum of modular forms $f_j$ on $\Gamma_{\infty, \epsilon}(N/p_j)$ where the $p_j$’s are the prime divisors of $N$. Furthermore, if $f$ is a cusp form then the $f_j$ can be chosen to be cusp forms.

Of course, Theorem 2.3 implies Conjecture 2.4 for $N$ a prime power. They are both analogous to results proved as parts of Atkin-Lehner theory on the curves $X_1(N)$. (Cf. Theorem 1 of Atkin-Lehner [1] or Lang [9], Theorem VIII.3.1.)

We let $\mathbb{S}_k(\Gamma_{\infty, \epsilon}(N))$ be the quotient of $S_k(\Gamma_{\infty, \epsilon}(N))$ by the subgroup of forms $f$ whose Fourier coefficients $c_{m_1, m_2}(f)$ are zero unless $(m_1, N) > 1$. In the $X_1(N)$ case, this would have the effect of replacing $S_k(\Gamma_1(N))$ by a space with the same Hecke eigenspaces but where each eigenspace is one-dimensional, generated by the newform in that eigenspace; we shall see in Theorem 5.6 that Hecke eigenspaces in $\mathbb{S}_k(\Gamma_{\infty, \epsilon}(N))$ are also one-dimensional. Finally, we let

$$S_{k, \infty}(N) = \prod_{\epsilon \in (\mathbb{Z}/N\mathbb{Z})^*} S_k(\Gamma_{\infty, \epsilon}(N)),$$

and we let

$$\mathbb{S}_{k, \infty}(N) = \prod_{\epsilon \in (\mathbb{Z}/N\mathbb{Z})^*} \mathbb{S}_k(\Gamma_{\infty, \epsilon}(N)).$$

Note that in the definitions of $\mathbb{S}_{k, \infty}(N)$ and $S_{k, \infty}(N)$ it’s enough to assume that the Fourier coefficients are zero unless $(m_1, N) > 1$ (or unless $(m_2, N) > 1$), by Proposition 2.4.
Proposition 2.7. The spaces $S_{(2, 2)}(\Gamma_{\geq, \epsilon}(p))$ and $\overline{S}_{(2, 2)}(\Gamma_{\geq, \epsilon}(p))$ are equal, as are the spaces $S_{(2, 2), \geq}(p)$ and $\overline{S}_{(2, 2), \geq}(p)$.

Proof. We have to show that if $f$ is an element of $S_{(2, 2)}(\Gamma_{\geq, \epsilon}(p))$ such that $c_{m_1, m_2}(f) = 0$ unless $p|m_1$ then $f$ is zero. Theorem 2.4 implies that such an $f$ is in fact a form on $\Gamma_{\geq, \epsilon}(1)$. By Corollary 2.4, $f$ can be considered to be an element of $S_2(\Gamma(1)) \otimes S_2(\Gamma(1))$. But $S_2(\Gamma(1))$ is zero, so $f$ is zero.

Proposition 2.8. If $p$ is a prime then

$$\dim S_k(\Gamma_{\geq, \epsilon}(p^l)) = \sum_{j=0}^{l-1} \dim S_k(\Gamma_{\geq, \epsilon}(p^j)).$$

Proof. This follows immediately from Theorem 2.3.

Conjecture 2.3 would imply a similar statement for forms of arbitrary level.

3 Hecke Operators on $X_{\geq, \epsilon}(N)$

Set

$$\Delta_{\geq, \epsilon}(N) = \left\{ \begin{pmatrix} a_1 & b_1 \\ c_1 & d_1 \end{pmatrix}, \begin{pmatrix} a_2 & b_2 \\ c_2 & d_2 \end{pmatrix} \mid a_i, b_i, c_i, d_i \in \mathbb{Z}, \right. \left. a_i d_i - b_i c_i > 0, \ (a_i d_i - b_i c_i, N) = 1, \right. \left. a_1 \equiv a_2 \pmod{N}, \right. \left. b_1 \equiv b_2 \pmod{N}, \right. \left. c_1 \equiv c_2 \pmod{N}, \right. \left. d_1 \equiv d_2 \pmod{N} \right\}.$$ 

We can partition $\Delta_{\geq, \epsilon}(N)$ into double $\Gamma_{\geq, \epsilon}(N)$-cosets; each double coset is called a Hecke operator. They act on the spaces of modular forms as follows:

Let $\gamma = (\gamma_1, \gamma_2)$ be an element of $\Delta_{\geq, \epsilon}(N)$, and let

$$\Gamma_{\geq, \epsilon}(N) \gamma \Gamma_{\geq, \epsilon}(N) = \prod_j \Gamma_{\geq, \epsilon}(N) \gamma_j$$

be a decomposition of the double coset generated by $\gamma$ into left cosets. Then for a form $f$ in $M(k_1, k_2)(\Gamma_{\geq, \epsilon}(N))$, we define

$$f|_{(k_1, k_2), \Gamma_{\geq, \epsilon}(N) \gamma \Gamma_{\geq, \epsilon}(N)} = \det(\gamma_1)^{(k_1/2)-1} \det(\gamma_2)^{(k_2/2)-1} \sum_j f|_{(k_1, k_2), \gamma_j}.$$ 

We see as in Shimura [3], Chapter 3, that $f|_{(k_1, k_2), \Gamma_{\geq, \epsilon}(N) \gamma \Gamma_{\geq, \epsilon}(N)}$ is an element of the space $M(k_1, k_2)(\Gamma_{\geq, \epsilon}(N))$, that cusp forms are transformed into cusp forms, and that the product of two Hecke operators is a sum of Hecke operators.

Let $T_{n_1, n_2}$ be the operator given by the sum of the double cosets containing elements $(\gamma_1, \gamma_2)$ where $\det(\gamma_1) = n_1$. This is zero unless $n_1 \equiv n_2 \pmod{N}$ and $(n_i, N) = 1$. Left coset representatives for it are given as follows:
Proposition 3.1. Let $(n_1, n_2)$ be a pair of positive integers that are congruent mod $N$ and that are relatively prime to $N$. The set of elements of $\Delta^*_{\gamma, \epsilon}(N)$ that have determinant $(n_1, n_2)$ then has the following left coset decomposition:

$$\prod_{a_1, a_2 > 0 \atop a_1 a_2 = n_1} \prod_{b, d_1 = n_1 \atop 0 \leq b < d_1} \Gamma_{\gamma, \epsilon}(N) \left( \sigma_{a_1} \begin{pmatrix} a_1 & b_1 N \\ 0 & d_1 \end{pmatrix}, \sigma_{a_2} \begin{pmatrix} a_2 & b_2 N \\ 0 & d_2 \end{pmatrix} \right)$$

where, for $a \in (\mathbb{Z}/N\mathbb{Z})^*$, $\sigma_a$ is any matrix in $\Gamma(1)$ that is congruent to $\begin{pmatrix} a^{-1} & 0 \\ 0 & a \end{pmatrix}$ mod $N$.

Proof. First, note that the above cosets do indeed occur in $T_{n_1, n_2}$. Also, it is easy to see that the above cosets are disjoint. Thus, we have to show that the cosets cover all of $T_{n_1, n_2}$.

Let $(\delta_1, \delta_2)$ be an element of $\Delta^*_{\gamma, \epsilon}(N)$ with determinant $(n_1, n_2)$. By Shimura [12], Proposition 3.36, we can multiply $\delta_1$ on the left by an element of $\Gamma(1)$ to get it into the form $\begin{pmatrix} a_1 & b_1 \\ 0 & d_1 \end{pmatrix}$, with $a_1 > 0$, $a_1 d_1 = n_1$, and $0 \leq b_1 < d_1$. Subsequently multiplying it on the left by an element of the form $\begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix}$ will put it into the form $\begin{pmatrix} a_1 & b_1 N \\ 0 & d_1 \end{pmatrix}$, but possibly with a different $b_1$. (We can still force $b_1$ to be in the range $0 \leq b_1 < d_1$, however.) And since $\sigma_{a_1}$ is an element of $\Gamma(1)$, we have shown that there is an element $\gamma_1 \gamma_2$ of $\Gamma(1)$ such that $\gamma_1 \delta_1$ is of the form $\sigma_{a_1} \begin{pmatrix} a_1 & b_1 N \\ 0 & d_1 \end{pmatrix}$.

We can choose an element $\gamma_2$ of $\Gamma(1)$ such that $\gamma_1 \gamma_2$ is in $\Gamma_{\gamma, \epsilon}(N)$: reduce $\gamma_1$ mod $N$, apply $\theta_\epsilon$ to it, and lift it back to $\Gamma(1)$. Multiplying $(\delta_1, \delta_2)$ on the left by $(\gamma_1, \gamma_2)$, we can thus assume that $\delta_1$ is of the form $\sigma_{a_1} \begin{pmatrix} a_1 & b_1 N \\ 0 & d_1 \end{pmatrix}$. But then the congruence relations force $\delta_2$ to be congruent to the matrix

$$\begin{pmatrix} 1 & 0 \\ 0 & n_1 \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & n_2 \end{pmatrix} \pmod{N}.$$

Now that we have fixed $\delta_1$ to be of the correct form, we still have to force $\delta_2$ to be of the correct form, and we are only allowed to multiply $\delta_2$ on the left by elements of $\Gamma_w(N)$. Thus, we need to find an element $\gamma_2'$ of $\Gamma_w(N)$ such that $\gamma_2' \delta_2$ is of the form $\sigma_{a_2} \begin{pmatrix} a_2 & b_2 N \\ 0 & d_2 \end{pmatrix}$. However, $\delta_2$ is in what Shimura calls $\Delta'$ (see Shimura [12], p. 68), so we can indeed find such a $\gamma_2'$ by Proposition 3.36 of Shimura [12].

The action of the Hecke operators $T_{n_1, n_2}$ descends to the spaces $S_k(\Gamma_{\gamma, \epsilon}(N))$:

**Proposition 3.2.** If $f$ is a form in $S_k(\Gamma_{\gamma, \epsilon}(N))$ such that $c_{m_1, m_2}(f) = 0$ unless $(N, m_i) > 1$ then $T_{n_1, n_2} f$ has the same property for all $n_1 \equiv n_2 \pmod{N}$.

Proof. For $d | N$, define the operator $i_d$ by

$$i_d(f) = \sum_{m_1, m_2 > 0 \atop d | m_1, m_2} c_{m_1, m_2}(f) q_1^{m_1} q_2^{m_2};$$

it has an equivalent definition as

$$i_d(f) = \frac{1}{d} \sum_{0 \leq \epsilon < d} f \left( \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & N \epsilon / d \\ 0 & 1 \end{pmatrix} \right).$$

By the principle of inclusion and exclusion, the statement that $c_{m_1, m_2}(f) = 0$ unless $(N, m_i) > 1$ is equivalent to having

$$f = \sum_{p | N} i_p(f) - \sum_{p_1, p_2 | N, p_1 < p_2} i_{p_1, p_2}(f) + \cdots,$$
and we want to show that if that is the case for $f$ then it is also the case for $T_{n_1,n_2}f$. It is therefore enough to show that $T_{n_1,n_2}$ commutes with any $i_d$. But
\[
\begin{pmatrix}
1 & eN/d \\
0 & 1
\end{pmatrix}
\sigma_{a_2}
\begin{pmatrix}
a_2 & b_2N \\
0 & d_2
\end{pmatrix}
\]
is congruent to
\[
\sigma_{a_2}
\begin{pmatrix}
a_2 & b_2N \\
0 & d_2
\end{pmatrix}
\begin{pmatrix}
1 & en_2N/d \\
0 & 1
\end{pmatrix}
\mod N,
\]
so by Proposition 3.1, commuting with $T_{n_1,n_2}$ simply permutes the $e$'s that occur in our alternate definition of $i_d$.\hfill \Box

Proposition 3.2 would be an easy corollary to Conjecture 2.6.

**Proposition 3.3.** For all $(\delta_1, \delta_2) \in \Delta^\pm(N)$, the $\Gamma_{\pm,e}(N)$-double cosets generated by $(\delta_1, \delta_2)$ and $(\delta'_1, \delta'_2)$ are equal, where
\[
\begin{pmatrix}
a & b \\
c & d
\end{pmatrix}^i = \begin{pmatrix}d & -b \\
-c & a\end{pmatrix}.
\]

**Proof.** We need to find matrices $(\gamma_1, \gamma_2)$ and $(\gamma'_1, \gamma'_2)$ in $\Gamma_{\pm,e}(N)$ such that
\[
(\gamma_1 \delta_1, \gamma_2 \delta_2) = (\delta'_1 \gamma'_1, \delta'_2 \gamma'_2).
\]
Since $\delta_1$ and $\delta'_1$ have the same elementary divisors, we can choose a $\gamma_1$ and $\gamma'_1$ that give us equality on the first coordinate. Now pick $\gamma_2$ and $\gamma'_2$ such that $(\gamma_1, \gamma_2)$ and $(\gamma'_1, \gamma'_2)$ are in $\Gamma_{\pm,e}(N)$. Then $\gamma_2 \delta_2 \equiv \delta'_2 \gamma'_2 \mod N$. But by Shimura [12], Lemma 3.29(1), we can then change $\gamma_2$ and $\gamma'_2$ by elements of $\Gamma_u(N)$ so that $\gamma_2 \delta_2 = \delta'_2 \gamma'_2$, as desired.\hfill \Box

We can define a Petersson inner product on the space of weight $(k_1, k_2)$ cusp forms just as in the one-variable case:
\[
\langle f, g \rangle = \int_{\Gamma_{\pm,e}(N) \backslash \mathbb{H} \times \mathbb{H}} f(z_1)\overline{g(z_2)} y_1^{k_1-2} y_2^{k_2-2} dx_1 dx_2 dy_1 dy_2
\]
(where $z_i = x_i + \sqrt{-1} y_i$); then just as in Shimura [12], Formula (3.4.5), we see that the Hecke operators $\Gamma_{\pm,e}(N)(\delta_1, \delta_2)\Gamma_{\pm,e}(N)$ and $\Gamma_{\pm,e}(N)(\delta'_1, \delta'_2)\Gamma_{\pm,e}(N)$ are adjoint with respect to that inner product. Thus:

**Corollary 3.4.** The $\mathbb{Z}$-algebra generated by the Hecke operators is a commutative algebra; the Hecke operators are self-adjoint with respect to the Petersson inner product on $S_k(\Gamma_{\pm,e}(N))$ and simultaneously diagonalizable.

**Proof.** The self-adjointness follows from Proposition 3.3 by the above discussion; the commutativity follows from Proposition 3.3 and Shimura [12], Proposition 3.8, and the simultaneous diagonalizability follows from the self-adjointness.\hfill \Box

The effect of Hecke operators on Fourier expansions is given as follows:
Proposition 3.5. Let $f$ be an element of $M_{(k_1,k_2)}(\Gamma_{\infty,\epsilon}(N))$; if $\alpha$ is an element of $(\mathbb{Z}/N\mathbb{Z})^*$, let $f|_{\left(\alpha, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right)}$ have the Fourier expansion

$$
f|_{\left(\alpha, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right)}(z_1, z_2) = \sum_{m_1, m_2 \geq 0} c_{m_1, m_2} \gamma_1^{m_1} \gamma_2^{m_2}.
$$

If we set

$$T_{n_1,n_2} f(z_1, z_2) = \sum_{m_1, m_2 \geq 0} d_{m_1, m_2} \gamma_1^{m_1} \gamma_2^{m_2}$$

then the $d_{m_1, m_2}$'s are given by

$$d_{m_1, m_2} = \sum_{a_1, a_2 > 0 \atop a_1 \equiv m_1 \pmod{a_i}} a_1^{k_1-1} a_2^{k_2-1} c_{a_1/a_2, m_1} a_1^{a_1} a_2^{a_2} a_2^{m_2} a_2^{m_2}.$$

Proof. The proof is entirely parallel to the proof of the analogous fact in the one-variable case; c.f. Shimura [2], (3.5.12).

Note that the matrices $\left(\alpha, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right)$ don’t normalize $\Gamma_{\infty,\epsilon}(N)$. This is why we have to introduce the functions $f_\alpha$ instead of simply diagonalizing $M_k(\Gamma_{\infty,\epsilon}(N))$.

Corollary 3.6. Let $f \in M_k(\Gamma_{\infty,\epsilon}(N))$ be a simultaneous eigenform for all of the Hecke operators. Then if $\lambda_{m_1, m_2}(f)$ is the eigenvalue for $T_{m_1, m_2}$, we have

$$c_{m_1, m_2}(f) = \lambda_{m_1, m_2}(f)c_{1,1}(f).$$

Unfortunately, this Corollary isn’t quite as useful as one might hope, since the above coefficients are all zero by Proposition 2.4 unless $\epsilon = -1!$ However, in that situation, we do get the following result:

Corollary 3.7. If $f$ and $g$ are elements of $S_k(\Gamma_{\infty,\epsilon^{-1}}(N))$ that are eigenfunctions for all $T_{n_1, n_2}$’s with the same eigenvalues then, considered as elements of $S_k(\Gamma_{\infty,\epsilon^{-1}}(N))$, they differ by a multiplicative constant.

Proof. By Proposition 2.4 and Corollary 3.6 if $c = c_{1,1}(f)/c_{1,1}(g)$ then $c_{m_1, m_2}(f - cg)$ is zero unless $(m_1, N) > 1$.

This can be restated as follows: let $T_{k,\epsilon}(N)$ be the $\mathbb{C}$-algebra of endomorphisms of $S_k(\Gamma_{\infty,\epsilon}(N))$ generated by the Hecke operators $T_{n_1, n_2}$ for $n_1 \equiv n_2 \pmod{N}$. Then:

Proposition 3.8. The space $S_k(\Gamma_{\infty,\epsilon^{-1}}(N))$ is a free module of rank one over $T_{k,\epsilon^{-1}}(N)$.

Proof. By Corollary 3.4, we can find a basis for $S_k(\Gamma_{\infty,\epsilon^{-1}}(N))$ consisting of simultaneous eigenforms for all of the elements of $T_{k,\epsilon^{-1}}(N)$. Furthermore, by Corollary 3.7, no two of those eigenforms have the same eigenvalues. This implies our Proposition.

Similarly, we define $T_{k,\epsilon}(N)$ to be the $\mathbb{C}$-algebra of endomorphisms of $S_k(\Gamma_{\infty,\epsilon}(N))$ generated by the Hecke operators $T_{n_1, n_2}$ for $n_1 \equiv n_2 \pmod{N}$. Proposition 2.4 tells us that the spaces $S_{(2,2)}(\Gamma_{\infty,\epsilon}(p))$ and $S_{(2,2)}(\Gamma_{\infty,\epsilon}(p))$ are equal; thus, the above Proposition has the following Corollary:
Corollary 3.9. The space $S_{(2,2)}(\Gamma_{\infty,-1}(p))$ is a free module of rank one over $T^*_{(2,2),-1}(p)$.  

With a little bit more care, we can use the above techniques to prove similar facts for $\epsilon = -k^2$ instead of just $\epsilon = -1$. (This isn’t too surprising, since $X_{\infty,-1}(N)$ and $X_{\infty,-k^2}(N)$ are isomorphic.) They are in fact true for arbitrary $\epsilon$; the proof demands different techniques, and will be given as Theorem 5.6. It does seem that $X_{\infty,-1}(N)$ is the “dominant” $X_{\infty,\epsilon}(N)$; see Sections 5 and 6 for further discussion of this matter.

Finally, we let $T^*_\epsilon(N)$ denote the free polynomial algebra over $C$ with variables $T_{n_1,n_2}$ for every pair $n_1,n_2$ of positive integers that are relatively prime to $N$ and congruent mod $N$. This algebra acts on the spaces $S_k(\Gamma_{\infty,\epsilon}(N))$ and $\mathcal{F}_k(\Gamma_{\infty,\epsilon}(N))$ for all $k$ and $\epsilon$; its image in the endomorphism rings of those spaces gives us the algebras $T^*_{k,\epsilon}(N)$ and $\mathcal{F}^*_{k,\epsilon}(N)$ that we defined above.

4 Hecke Operators on $X_{\infty}(N)$

The Hecke operators $T_{n_1,n_2}$ defined above have the following modular interpretation: let $(E_1, E_2, \phi)$ be a point of $X_{\infty,\epsilon}(N)$, and let $\pi_i: E_i \to E'_i$ be maps of elliptic curves of degree $n_i$, where $(n_i, N) = 1$. Then $\phi$ induces a map from $E'_1[N]$ to $E'_2[N]$ which is an isomorphism of group schemes; $T_{n_1,n_2}$ sends our point to the sum of all points $(E'_1, E'_2, \phi)$ that arise in such a fashion. Why, then, do we impose the restriction that $n_1$ be congruent to $n_2$ mod $N$? The answer is that, if $\pi: E \to E'$ is a map of degree $n$ (with $(n, N) = 1$) then $\pi$ doesn’t preserve the Weil pairing:

$$\langle x, \pi y \rangle = \langle x, \pi' y \rangle$$

$$= \langle x, [n] y \rangle$$

$$= \langle x, y \rangle^n.$$ 

So if $\phi$ raises the Weil pairing to the $\epsilon$’th power then, if we push it forward via maps of order $n_i$ as above, the resulting map raises the Weil pairing to the $\epsilon n_1/n_2$ power. This explains why we had to assume that $n_1 \equiv n_2 \pmod{N}$ for the Hecke operators to act on the surfaces $X_{\infty,\epsilon}(N)$. However, we should have Hecke operators $T_{n_1,n_2}$ for arbitrary $n_i$ with $(n_i, N) = 1$ which act on the surface $X_{\infty}(N)$.

The above considerations, when translated into matrices, lead us to the following definition: for any $\epsilon, \epsilon'$ in $(\mathbb{Z}/N\mathbb{Z})^*$, set

$$\Delta^*_{\infty,\epsilon,\epsilon'}(N) = \left\{ \begin{pmatrix} a_1 & b_1 \\ c_1 & d_1 \end{pmatrix}, \begin{pmatrix} a_2 & b_2 \\ c_2 & d_2 \end{pmatrix} \mid a_1, b_1, c_1, d_1 \in \mathbb{Z}, a_2d_2 - b_2c_2 > 0, (a_1d_1 - b_1c_1, N) = 1, a_1 \equiv a_2 \pmod{N}, b_1 \equiv \epsilon' b_2 \pmod{N}, c_1 \equiv c_2 \pmod{N}, ed_1 \equiv \epsilon' d_2 \pmod{N} \right\}.$$ 

It is obvious from the definitions that $\Delta^*_{\infty,\epsilon,\epsilon} = \Delta^*_{\infty,\epsilon}$ and one easily checks that

$$\Delta^*_{\infty,\epsilon,\epsilon'} \cdot \Delta^*_{\infty,\epsilon',\epsilon''} \subset \Delta^*_{\infty,\epsilon,\epsilon''}.$$ 

These facts imply in particular that $\Delta^*_{\infty,\epsilon,\epsilon'}$ is invariant under multiplication by $\Gamma_{\infty,\epsilon}(N)$ on the left and by $\Gamma_{\infty,\epsilon'}(N)$ on the right; thus, $\Delta^*_{\infty,\epsilon,\epsilon'}$ can be partitioned into Hecke operators that send forms on $X_{\infty,\epsilon}(N)$ to forms on $X_{\infty,\epsilon'}(N)$. For any $n_1$ and $n_2$ with $(n_1, N) = 1$ and with
\( \epsilon n_1 \equiv \epsilon' n_2 \mod N \), we define the Hecke operator \( T_{n_1, n_2} \) to be the sum of the double cosets \( \Gamma_{\rho, \epsilon'}(N)\{\gamma_1, \gamma_2 \} \Gamma_{\rho, \epsilon'}(N) \) occurring in \( \Delta_{\rho, \epsilon'} \), for which \( \det(\gamma_i) = n_i \). This does depend on \( \epsilon \), but it has a set of left coset representatives that is independent of \( \epsilon \).

**Proposition 4.1.** Let \( n_1 \) and \( n_2 \) be positive integers that are relatively prime to \( N \), and let \( \epsilon \) and \( \epsilon' \) be elements of \((\mathbb{Z}/N\mathbb{Z})^*\) such that \( \epsilon n_1 \equiv \epsilon' n_2 \mod N \). Then the set of elements of \( \Delta_{\rho, \epsilon'}(N) \) that have determinant \((n_1, n_2)\) has the following left coset decomposition:

\[
\prod_{a_1, a_2 > 0 \atop a_1 d_i = n_i, \atop 0 \leq b < d_i} \Gamma_{\rho, \epsilon'}(N) \left( \sigma_{a_1} \left( \begin{array}{cc} a_1 & b_1 N \\ 0 & d_1 \end{array} \right), \sigma_{a_2} \left( \begin{array}{cc} a_2 & b_2 N \\ 0 & d_2 \end{array} \right) \right)
\]

where, for \( a \in (\mathbb{Z}/N\mathbb{Z})^* \), \( \sigma_a \) is any matrix that is congruent to \( \left( \begin{array}{cc} a^{-1} & 0 \\ 0 & a \end{array} \right) \mod N \). Furthermore, the above left cosets are also disjoint as \( \Gamma(1) \times \Gamma(1) \) cosets.

**Proof.** The proof is the same as the proof of Proposition 3.1. \( \square \)

Recall that we defined

\[
S_{k, \rho}(N) = \bigoplus_{\rho \in (\mathbb{Z}/N\mathbb{Z})^*} S_k(\Gamma_{\rho, \epsilon'}(N))
\]

and made a similar definition for \( \mathfrak{S}_{k, \rho}(N) \). Also, if \( f \) is an element of \( S_{k, \rho}(N) \), we write \( f \) for its \( \rho \)th component. We then define Hecke operators \( T_{n_1, n_2} \) acting on the space \( S_{k, \rho}(N) \) by setting \( (T_{n_1, n_2}f)_\epsilon = T_{n_1, n_2}(f|_{n_2/n_1}) \); Proposition 4.1 shows that that action “looks the same” for all \( \epsilon \). The following Proposition shows that the action of these Hecke operators descends to the spaces \( \mathfrak{S}_{k}(\Gamma_{\rho, \epsilon'}(N)) \), and hence allows us to similarly define an action of them on the space \( \mathfrak{S}_{k, \rho}(N) \):

**Proposition 4.2.** If \( f \) is a form in \( S_k(\Gamma_{\rho, \epsilon'}(N)) \) such that \( c_{m_1, m_2}(f) = 0 \) unless \( (N, m_i) > 1 \) then \( T_{n_1, n_2}f \) has the same property for all \( n_i \) relatively prime to \( N \).

**Proof.** The proof is the same as the proof of Proposition 3.2. \( \square \)

The action on Fourier expansions is also as expected from Proposition 3.3, with the same proof:

**Proposition 4.3.** Let \( f \) be an element of \( M_{k_1, k_2}(\Gamma_{\rho, \epsilon'}(N)) \); if \( a \) is an element of \((\mathbb{Z}/N\mathbb{Z})^*\), let

\[
\hat{f}\left| \left( \sigma_a \left( \begin{array}{cc} 0 & q_1 \\ 1 & 0 \end{array} \right) \right) (z_1, z_2) = \sum_{m_1, m_2 \geq 0} c_{a, m_1, m_2} q_1^{m_1} q_2^{m_2}.
\]

If we set

\[
T_{n_1, n_2}f(z_1, z_2) = \sum_{m_1, m_2 \geq 0} d_{m_1, m_2} q_1^{m_1} q_2^{m_2}
\]

then the \( d_{m_1, m_2} \)'s are given by

\[
d_{m_1, m_2} = \sum_{a_1, a_2 > 0 \atop a_1 \mid (m_1, n_1)} d_1^{k_1 - 1} d_2^{k_2 - 1} c(a_1/a_2, m_1 n_1/a_1^2, m_2 n_2/a_2^2).
\]

\( \square \)
This Proposition (or Proposition 4.1, which it is a corollary of) allows us to translate theorems about forms on $X_w(N)$ into theorems about forms on $X_{\infty}(N)$: if $f$ is a form on some $X_{\infty,e}(N)$ and we have a Hecke operator $T_{n_1,n_2}$, we can consider $f$ to be form on $X_w(N) \times X_w(N)$ and apply $T_{n_1} \times T_{n_2}$ to it there. This gives us a form on $X_w(N) \times X_w(N)$; but by Proposition 4.4, that has the same effect as directly applying the $T_{n_1,n_2}$ that we have defined above to $f$ considered as a form on $X_{\infty,e}(N)$, so our resulting form, which is a priori only a form on $X_w(N) \times X_w(N)$, is really a form on $X_{\infty,e,m_1/n_2}(N)$. Thus, the fact that the Hecke operators $T_n$ (with $(n,N) = 1$) on $X_w(N)$ commute implies that our Hecke operators $T_{n_1,n_2}$ commute. Similarly, we can define a Petersson inner product on $S_{k,\infty}(N)$ by taking the orthogonal direct sum of the inner products on the $S_k(\Gamma_{\infty,e}(N))$’s; our Hecke operators are then normal with respect to that inner product because the Hecke operators on $X_w(N)$ are.

It is frequently useful to encapsulate this relation between forms on $X_{\infty}(N)$ and forms on $X_w(N)$ by defining a map $\Sigma: \mathcal{S}_{k,\infty}(N) \rightarrow \mathcal{S}_{k_1}(\Gamma_w(N)) \otimes \mathcal{S}_{k_2}(\Gamma_w(N))$ which sends $f \in \mathcal{S}_{k,\infty}(N)$ to $\sum_{\epsilon \in \mathbb{Z}/N\mathbb{Z}} \Sigma f_\epsilon$. By $\mathcal{S}_{k_i}(\Gamma_w(N))$ we mean $\mathcal{S}_{k_i}(\Gamma_w(N))/V$ where $V$ is the space of forms $f \in \mathcal{S}_{k_i}(\Gamma_w(N))$ such that $c_m(f) = 0$ unless $(m,k_i) > 1$; it is a module over the Hecke algebra generated by the operators $T_n$ with $(n,N) = 1$, and its eigenspaces for that algebra are one-dimensional. The following two Propositions then sum up the discussion of the previous paragraph:

**Proposition 4.4.** The map from $\mathcal{S}_{k,\infty}(N)$ to $\mathcal{S}_{k_1}(\Gamma_w(N)) \otimes \mathcal{S}_{k_2}(\Gamma_w(N))$ that sends a form $f$ to $\sum_{\epsilon \in \mathbb{Z}/N\mathbb{Z}} \Sigma f_\epsilon$ commutes with the action of Hecke operators. It descends to an injection $\Sigma$ from $\mathcal{S}_{k,\infty}(N)$ to $\mathcal{S}_{k_1}(\Gamma_w(N)) \otimes \mathcal{S}_{k_2}(\Gamma_w(N))$; if $f \in \mathcal{S}_{k,\infty}(N)$ then

$$f\epsilon = \sum_{m_1,m_2 \geq 0 \atop (m_1,N) = 1} c_{m_1,m_2}(\Sigma f)q_1^{m_1}q_2^{m_2}.$$ 

**Proof.** The only parts that remain to be proved are that $\Sigma$ is an injection and that $f\epsilon$ can be recovered in the given manner. First, we note that, for all $m_1, m_2$ with $(m_i,N) = 1$,

$$c_{m_1,m_2}(\Sigma f) = \sum_{\epsilon \in \mathbb{Z}/N\mathbb{Z}} c_{m_1,m_2}(f\epsilon).$$

But Proposition 4.3 says that $c_{m_1,m_2}(f\epsilon) = 0$ unless $\epsilon \equiv -m_2/m_1 \pmod{N}$; $c_{m_1,m_2}(\Sigma f)$ therefore equals $c_{m_1,m_2}(f_{-m_2/m_1})$. This together with Proposition 4.4 immediately implies our formula for $f\epsilon$. And if $\Sigma f = 0$ then this implies that, for all $\epsilon$ and for all $m_i$ such that $\epsilon \equiv -m_2/m_1 \pmod{N}$, $c_{m_1,m_2}(f\epsilon)$ is zero. But that implies that $f\epsilon = 0$ by using Proposition 2.4 again. \qed

**Proposition 4.5.** The $\mathbb{Z}$-algebra generated by the Hecke operators $T_{n_1,n_2}$ acting on $\mathcal{S}_{k,\infty}(N)$ is a commutative algebra; the Hecke operators are normal with respect to the Petersson inner product on $\mathcal{S}_{k,\infty}(N)$ and simultaneously diagonalizable.

**Proof.** This follows from the above reduction of these facts to facts about forms on $X_w(N)$ and from Shimura [12], Theorem 3.41. \qed

Let $f$ be an element of $\mathcal{S}_{k,\infty}(N)$, and let $m_1$ and $m_2$ be integers relatively prime to $N$. We define $c_{m_1,m_2}(f)$ to be equal to $c_{m_1,m_2}(f_{-m_2/m_1})$. We also make the same definition for $f \in \mathcal{S}_{k,\infty}(N)$. If we set $f = \sum_{\epsilon \in \mathbb{Z}/N\mathbb{Z}} f\epsilon$, then $f$ is a form on $X_w(N) \times X_w(N)$, and $c_{m_1,m_2}(f) = c_{m_1,m_2}(f)$, by Proposition 2.4, as noted in the proof of Proposition 4.4.
Proposition 4.6. Let \( f \) be an element of \( S_{k, \infty}(N) \); for \( a \in (\mathbb{Z}/N \mathbb{Z})^* \), let \( f_a \) be defined by

\[
(f_a)_\epsilon = f_{(a^{-2}\epsilon)}(\sigma_a, (\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix})).
\]

Then for all \( n_1, n_2 \) with \( (n_i, N) = 1 \) and for all \( m_1, m_2 \) with \( (m_i, N) = 1 \), we have

\[
c_{m_1, m_2}(T_{n_1, n_2}f) = \sum_{a_1, a_2 > 0 \atop a_i | (m_i, n_i)} a_1^{k_1-1}a_2^{k_2-1}c_{m_1n_1/a_1^2, m_2n_2/a_2^2}(f_{a_1/a_2}).
\]

Proof. This is a corollary of Proposition 4.3. 

We define \( T^*_k(N) \) to be the free polynomial algebra over \( C \) with generators \( T_{n_1, n_2} \) for each pair \( n_1, n_2 \) of positive integers that are relatively prime to \( N \). We define \( T^*_{k, \infty}(N) \) to be its image in the endomorphism ring of \( S_{k, \infty}(N) \); we define \( T_{k, \infty}(N) \) to be its image in the endomorphism ring of \( S_{k, \infty}(N) \).

Corollary 4.7. If \( f \in S_{k, \infty}(N) \) is a simultaneous eigenform for all Hecke operators \( T_{n_1, n_2} \) in \( T^*_{k, \infty}(N) \) with eigenvalues \( \lambda_{n_1, n_2}(f) \) then, for all \( m_1 \) and \( m_2 \) with \( (m_i, N) = 1 \), we have

\[
c_{m_1, m_2}(f) = \lambda_{m_1, m_2}(f)c_{1, 1}(f).
\]

Thus, if \( f \) is a non-zero element of \( S_{k, \infty}(N) \) that is an eigenform for all the \( T_{n_1, n_2} \)'s then \( c_{1, 1}(f) \) is also non-zero; we call such an \( f \) a normalized eigenform if \( c_{1, 1}(f) = 1 \).

Corollary 4.8. The space \( S_{k, \infty}(N) \) is a free module of rank one over \( T_{k, \infty}(N) \).

Proof. By Proposition 4.3, we can find a basis for \( S_{k, \infty}(N) \) consisting of simultaneous eigenforms for all elements of \( T_{k, \infty}(N) \); the previous Corollary shows that the eigenspaces are one-dimensional, implying this Corollary.

Corollary 4.9. The space \( S_{(2, 2), \infty}(p) \) is a free module of rank one over \( T^*_{(2, 2), \infty}(p) \).

Proof. This follows from Corollary 4.8 and Proposition 2.7.

There is a special class of operators contained in our Hecke algebras \( T^*_k(N) \). Given elements \( \epsilon \) and \( a \) of \( (\mathbb{Z}/N \mathbb{Z})^* \), we have

\[
(1, \sigma_a)^{-1} \Gamma_{\infty, \epsilon}(N)(1, \sigma_a) = \Gamma_{\infty, a^{-2}\epsilon}(N).
\]

The action of \( (1, \sigma_a) \) therefore gives an isomorphism from \( S_k(\Gamma_{\infty, \epsilon}(N)) \) to \( S_k(\Gamma_{\infty, a^{-2}\epsilon}(N)) \), denoted by \( \langle a \rangle \); as with the operators \( T_{n_1, n_2}, \langle a \rangle \) extends to the spaces \( S_{k, \infty}(N) \) and \( S^*_{k, \infty}(N) \) via the definition \( \langle (a)f \rangle = \langle a \rangle(\langle f \rangle_{\epsilon}) \). Furthermore, the action is the same if we multiply \( (1, \sigma_a) \) by \( (\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}) \); however, if we consider it as an operator on \( X_w(N) \times X_w(N) \), as in the discussion before Proposition 4.4, then this, up to a constant, is the product of the identity with the Hecke operator \( T(a, a) \). By Shimura [12], Theorem 3.24(4), \( T(a, a) \) is in the \( \mathbb{Q} \)-algebra generated by the \( T(n) \)'s, so \( \langle a \rangle \) is in \( T^*_k(N) \). Thus:

Proposition 4.10. For all \( a \in (\mathbb{Z}/N \mathbb{Z})^* \), the operator \( \langle a \rangle \) given by the action of \( (1, \sigma_a) \) is an isomorphism from \( S_k(\Gamma_{\infty, \epsilon}(N)) \) to \( S_k(\Gamma_{\infty, a^{-2}\epsilon}(N)) \); furthermore, it is contained in \( T^*_k(N) \).
5 Relationships between the Spaces \( \overline{S}_{k, \sim}(N) \), \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \), and \( \overline{S}_k(\Gamma_{\sim, -1}(N)) \)

When trying to prove that Hecke eigenspaces in \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \) are one-dimensional, we ran into problems because forms are “missing” Fourier coefficients: in particular, they don’t have a \((1,1)\) Fourier coefficient unless \( \epsilon \equiv -1 \pmod{N} \), so we couldn’t simply use Corollary 3.6. However, the space \( \overline{S}_{k, \sim}(N) \) doesn’t have that problem, and there is a natural projection map from \( \overline{S}_{k, \sim}(N) \) to \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \). This gives us a replacement for the missing Fourier coefficients: it also gives us a framework for seeing how the spaces \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \) differ (as \( T_\epsilon^*(N) \)-modules) as \( \epsilon \) varies.

The key Lemma here is the following:

**Lemma 5.1.** The space \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \) has a basis consisting of simultaneous \( T_{k, \epsilon}(N) \)-eigenforms \( f \) that are of the form \( f_\lambda \) for simultaneous \( T_{k, \sim}(N) \)-eigenforms \( f \in \overline{S}_{k, \sim}(N) \).

**Proof.** If \( f \in \overline{S}_{k, \sim}(N) \) is a \( T_{k, \sim}(N) \)-eigenform then it is certainly an eigenform for those Hecke operators \( T_{n_1, n_2} \) where \( n_1 \equiv n_2 \pmod{N} \); its \( \epsilon \)-component \( f_\lambda \) is therefore an eigenform for those operators as well. The Lemma then follows from the fact that \( \overline{S}_{k, \sim}(N) \) has a basis of eigenforms, by Proposition 4.5. \( \square \)

It is possible for two different \( T_{k, \sim}(N) \)-eigenforms in \( \overline{S}_{k, \sim}(N) \) to project to the same \( T_{k, \epsilon}(N) \)-eigenform in \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \); we shall discuss this in Theorem 5.3. Also, some eigenforms in \( \overline{S}_{k, \sim}(N) \) project to zero for some choices of \( \epsilon \): see the comments after the proof of the following Proposition and Section 3. We shall state a slightly stronger version of this Lemma as Corollary 5.3.

**Proposition 5.2.** If \( f \in \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \) is a \( T_{k, \epsilon}(N) \)-eigenform then there is an \( T_{k, -1}(N) \)-eigenform \( g \in \overline{S}_k(\Gamma_{\sim, -1}(N)) \) such that \( c_{m_1, m_2}(g) = \lambda_{m_1, m_2}(f) \) for all \( m_1 \equiv m_2 \pmod{N} \).

**Proof.** By Lemma 5.1 there is an eigenform \( f \in \overline{S}_{k, \sim}(N) \) such that \( \lambda_{m_1, m_2}(f) = \lambda_{m_1, m_2}(f) \) for all \( m_1 \equiv m_2 \pmod{N} \). (We might a priori not be able to assume that \( f_\lambda = f \); however, \( f \) is a linear combination of eigenforms projecting from \( \overline{S}_{k, \sim}(N) \), so those eigenforms must have the same eigenvalues as \( f \).) We can assume that \( f \) is normalized. We then set \( g = f \cdot 1 \); it is a normalized eigenform contained in \( \overline{S}_k(\Gamma_{\sim, -1}(N)) \), and \( \lambda_{m_1, m_2}(g) = \lambda_{m_1, m_2}(f) = \lambda_{m_1, m_2}(f) \). But Corollary 3.6 then tells us that \( c_{m_1, m_2}(g) = \lambda_{m_1, m_2}(f) \). \( \square \)

Define \( \overline{K}_{k, \epsilon}(N) \) to be the subspace of \( \overline{S}_k(\Gamma_{\sim, -1}(N)) \) generated by eigenforms whose eigenvalues are those of an eigenform in \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \); define \( \overline{K}_{k, \epsilon}(N) \) to be the subspace of \( \overline{S}_k(\Gamma_{\sim, -1}(N)) \) generated by eigenforms which do not arise in such a fashion. The Hecke algebra \( \overline{T}_{k, \epsilon}(N) \) is isomorphic to the image of \( \overline{T}_{k, -1}(N) \) in the endomorphism ring of \( \overline{K}_{k, \epsilon}(N) \); both actions are diagonalizable, so the rings are isomorphic iff the same eigenvalues occur, which is the case by the definition of \( \overline{K}_{k, \epsilon}(N) \) and by Proposition 5.2. In fact, the spaces \( \overline{K}_{k, \epsilon}(N) \) and \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \) are isomorphic as \( T_\epsilon^*(N) \)-modules, because the eigenspaces in \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \) are one dimensional; we shall prove this fact later as Theorem 5.4. Thus, \( \overline{K}_{k, \epsilon}(N) \) measures the difference between \( \overline{S}_k(\Gamma_{\sim, -1}(N)) \) and \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \); we shall study this space in Section 3.

Since the proof of Proposition 5.2 involved lifting eigenforms in \( \overline{S}_k(\Gamma_{\sim, \epsilon}(N)) \) to eigenforms in \( \overline{S}_{k, \sim}(N) \), we’d like to see how ambiguous the choice of such a lifting is. The following Theorem answers that question:

**Theorem 5.3.** Let \( f \) be an eigenform in \( \overline{S}_k(\sim)(N) \), and let \( H \subset (\mathbb{Z}/N\mathbb{Z})^* \) be the set of \( \epsilon \) such that \( f_{-\epsilon} \neq 0 \). Then:
1. $H$ is a subgroup of $(\mathbb{Z}/N\mathbb{Z})^*$.

2. $H$ depends only on $\mathfrak{f}_{-1}$.

3. Every element of $(\mathbb{Z}/N\mathbb{Z})^*/H$ has order one or two.

4. If $g$ is another eigenform in $\overline{S}_{k,\mathbb{Z}}(N)$ then $g_{-1} = \mathfrak{f}_{-1}$ if and only if there is a character $\chi$ on $H$ such that $g_{-\epsilon} = \chi(\epsilon)\mathfrak{f}_{-\epsilon}$ for all $\epsilon \in H$.

First, we prove two Lemmas that we shall need during the proof of the Theorem.

**Lemma 5.4.** Let $f$ be an eigenform in $\overline{S}_{k,\mathbb{Z}}(N)$ and $\epsilon$ an element of $(\mathbb{Z}/N\mathbb{Z})^*$ such that $\mathfrak{f}_\epsilon \neq 0$. For any positive integers $m_1$ and $m_2$ there exist positive integers $n_1$ and $n_2$ such that $cn_1 + n_2 \equiv 0 \pmod{N}$, $(n_i, m_i) = 1$ for $i \in \{1, 2\}$, and $c_{n_1,n_2}(\mathfrak{f}_\epsilon) \neq 0$.

**Proof.** By Proposition 4.4, $\overline{f}$ is an eigenform in $\overline{S}_{k_1}(\Gamma_w(N)) \otimes \overline{S}_{k_2}(\Gamma_w(N))$. Since the eigenspaces in $\overline{S}_{k_i}(\Gamma_w(N))$ are one-dimensional, there must exist $f_i \in \overline{S}_{k_i}(\Gamma_w(N))$ such that $\overline{f} = f_1 \otimes f_2$.

For any $\epsilon \in (\mathbb{Z}/N\mathbb{Z})^*$, set

$$f_{i,\epsilon'} = \sum_{n \equiv \epsilon'(\mod N)} c_n(f_i)q^n.$$

It is also an element of $\overline{S}_{k_i}(\Gamma_w(N))$. (This follows easily from Shimura [12], Proposition 3.64.) Then

$$\mathfrak{f}_\epsilon = \sum_{\epsilon' \in (\mathbb{Z}/N\mathbb{Z})^*} f_{1,\epsilon'} \otimes f_{2,\epsilon'},$$

by Proposition 4.4.

Since $\mathfrak{f}_\epsilon \neq 0$, there exists $\epsilon' \in (\mathbb{Z}/N\mathbb{Z})^*$ such that $f_{1,\epsilon'}$ and $f_{2,\epsilon'}$ are both nonzero. By Lang [8], Theorem VIII.3.1, there exist $n_i$ such that $(n_i, Nm_i) = 1$ and that $c_{n_1}(f_{1,\epsilon'})$ and $c_{n_2}(f_{2,\epsilon'})$ are both non-zero. But Proposition 4.4 then implies that $c_{n_1,n_2}(\mathfrak{f}_\epsilon) \neq 0$, as desired. □

**Lemma 5.5.** Let $f$ be an eigenform in $\overline{S}_{k,\mathbb{Z}}(N)$ and $\epsilon$ an element of $(\mathbb{Z}/N\mathbb{Z})^*$ such that $\mathfrak{f}_\epsilon \neq 0$. Then $\mathfrak{f}_{-\epsilon^j}$ is non-zero for all $j$. In particular, $\mathfrak{f}_{-1/\epsilon}$ is non-zero.

**Proof.** We can assume that $\mathfrak{f}$ is a normalized eigenform. Since $\mathfrak{f}_{-\epsilon}$ is non-zero, there is some coefficient $\lambda = c_{m_1,m_2}(\mathfrak{f})$ that is non-zero, where $(m_i, N) = 1$ and $cm_1 \equiv m_2 \pmod{N}$. We therefore have $T_{m_1,m_2}(\mathfrak{f}) = \lambda \mathfrak{f}$, by Corollary 4.7, so for all $\epsilon' \in (\mathbb{Z}/N\mathbb{Z})^*$,

$$\lambda \mathfrak{f}_{-\epsilon'} = (T_{m_1,m_2}(\mathfrak{f})_{-\epsilon'})_{-\epsilon'} = T_{m_1,m_2}(\mathfrak{f}_{-\epsilon'}m_{2/m_1}) = T_{m_1,m_2}(\mathfrak{f}_{-\epsilon'}).$$

In particular, setting $\epsilon' = \epsilon^j$, we see that

$$\lambda \mathfrak{f}_{-\epsilon^j} = T_{m_1,m_2}(\mathfrak{f}_{-\epsilon^j+1}),$$

so if $\mathfrak{f}_{-\epsilon^j}$ is non-zero then, since $\lambda$ also is, $\mathfrak{f}_{-\epsilon^{j+1}}$ is as well, and we have our Lemma by induction. □
Proof of Theorem 5.3. We can assume that \( f \) is a normalized eigenform. To show that \( H \) is a subgroup, let \( e_1 \) and \( e_2 \) be elements of \( H \). Thus, there exist \( n_{1,i} \) and \( n_{2,i} \) (for \( i = 1, 2 \)) such that \( c_{n_{1,i},n_{2,i}}(f_{-i}) \) is non-zero; by Lemma 5.4 we can assume that \((n_{1,1}, n_{1,2}) = (n_{2,1}, n_{2,2}) = 1\), and by Proposition 2.4, \( \epsilon_{n_{1,i}} n_{2,i} \equiv n_{2,i} \pmod{N} \).

By Corollary 4.3, \( c_{n_{1,i},n_{2,i}}(f) = \lambda_{n_{1,i},n_{2,i}}(f) \). But
\[
\lambda_{n_{1,1},n_{2,1}}(f) = \lambda_{n_{1,1},n_{2,1}}(f) \lambda_{n_{1,2},n_{2,2}}(f),
\]
by our assumption that \((n_{1,1}, n_{1,2}) = 1\), and is therefore non-zero, as is the corresponding Fourier coefficient of \( f \). This is a Fourier coefficient of \( f \) for
\[
\epsilon \equiv - (n_{2,1} n_{2,2}/n_{1,1} n_{1,2})
\equiv - (n_{2,1}/n_{1,1}) (n_{2,2}/n_{1,2})
\equiv - \epsilon_1 \epsilon_2.
\]

Thus, \( \epsilon_1 \epsilon_2 \in H \), so \( H \) is a subgroup of \((\mathbb{Z}/N\mathbb{Z})^*\).

To see that every element of \((\mathbb{Z}/N\mathbb{Z})^*/H\) has order one or two, pick \( a \in (\mathbb{Z}/N\mathbb{Z})^* \) and let \( f \in \overline{T}_{k,\infty}(N) \) be an eigenform. Then \((a)f_{-1} = (a)(f_{-\lambda}), \) since \( (a) \) is an invertible operator contained in \( T_{k,\infty}(N) \), by Proposition 1.10, the fact that \( f_{-1} \neq 0 \) implies that \((a)f_{-1} \neq 0 \) as well, so \( f_{-\lambda} \neq 0 \) and \( \lambda^2 \in H \).

To show that \( H \) depends only on \( f_{-1} \), it’s enough to prove the last part of the Theorem. We shall prove that if \( g \) is an eigenform such that \( g_{-1} = f_{-1} \) then there is a character \( \chi \) on \( H \) such that \( g_{-\epsilon} = \chi(\epsilon)f_{-\epsilon} \); the converse (i.e. that \( g \)’s constructed in that fashion are eigenforms) follows easily from the definitions.

Thus, assume that we have normalized eigenforms \( f \) and \( g \) such that \( f_{-1} = g_{-1} \); let \( \epsilon \) be an element of \( H \), so \( f_{-\epsilon} \neq 0 \). By Lemma 5.4, \( f_{-1/\epsilon} \) is also non-zero. There then exist \( m_1 \) and \( m_2 \) relatively prime to \( N \) such that \( m_1 \equiv em_2 \pmod{N} \) and \( c_{m_1,m_2}(f) \neq 0 \). Therefore, \( \lambda_{m_1,m_2}(f) \) is also non-zero. And
\[
\lambda_{m_1,m_2}(f) f_{-\epsilon} = (T_{m_1,m_2}(f))_{-\epsilon}
= T_{m_1,m_2}(f_{-em_2/m_1})
= T_{m_1,m_2}(f_{-1})
= T_{m_1,m_2}(g_{-1})
= \lambda_{m_1,m_2}(g) g_{-\epsilon}.
\]

Since \( \lambda_{m_1,m_2}(f) \) and \( f_{-\epsilon} \) are both non-zero, this implies that \( \lambda_{m_1,m_2}(g) \) and \( g_{-\epsilon} \) are also both non-zero, and that if we define \( \chi(\epsilon) = \lambda_{m_1,m_2}(f)/\lambda_{m_1,m_2}(g) \) (for any choice of \( m_1 \) such that \( m_1 \equiv \equiv em_2 \pmod{N} \) and such that \( c_{m_1,m_2}(f_{-1/\epsilon}) \neq 0 \)) then \( g_{-\epsilon} = \chi(\epsilon)f_{-\epsilon} \), as desired. We then only have to show that \( \chi \) is a character, not just a function; that follows by using the same arguments that we used to show that \( H \) was a subgroup.

We now have all the tools necessary to prove that the spaces \( \overline{\mathcal{S}}_{k}(\Gamma_{\infty,\epsilon}(N)) \) are free of rank one over \( \overline{T}_{k,\epsilon}(N) \) for all \( \epsilon \in (\mathbb{Z}/N\mathbb{Z})^* \).

Theorem 5.6. For all \( \epsilon \in (\mathbb{Z}/N\mathbb{Z})^* \), all of the \( \overline{T}_{k,\epsilon}(N) \)-eigenspaces in \( \overline{\mathcal{S}}_{k}(\Gamma_{\infty,\epsilon}(N)) \) are one-dimensional, and the space \( \overline{\mathcal{S}}_{k}(\Gamma_{\infty,\epsilon}(N)) \) is a free module of rank one over \( \overline{T}_{k,\epsilon}(N) \).
Proof. Pick a $\mathbf{T}_{k,\epsilon}(N)$-eigenspace in $\mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$. By Lemma 5.1, it has a basis consisting of eigenforms of the form $f_\epsilon$, where $f$ is a normalized eigenform in $\mathfrak{S}_k(\Gamma_{\infty})$. Thus, we need to show that if $f$ and $g$ are normalized eigenforms in $\mathfrak{S}_k(\Gamma_{\infty})$ such that $f_\epsilon$ and $g_\epsilon$ are in the same eigenspace then $f_\epsilon$ and $g_\epsilon$ are in fact constant multiples of each other. However, $\lambda_{n_1,n_2}(f) = \lambda_{n_1,n_2}(g) = c_{n_1,n_2}(f)$, for all $n_1 \equiv n_2 \pmod{N}$, so the fact that $f_\epsilon$ and $g_\epsilon$ have the same eigenvalues simply means that $f_{-1}$ and $g_{-1}$ are equal. Theorem 5.3 then implies that $f_\epsilon$ and $g_\epsilon$ are multiples of each other. Thus, the eigenspaces are one-dimensional, and $\mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$ is indeed a free $\mathbf{T}_{k,\epsilon}(N)$-module of rank one. \thickbox

The basic idea behind the proof of Theorem 5.6 is that, if we have a form in $\mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$, we can use Lemma 5.1 to fill in the Fourier coefficients that are forced to vanish by Proposition 2.4. Of course, it’s often easiest just to work with $\mathfrak{S}_k(\Gamma_{\infty}(N))$ and $X_{\infty}(N)$ directly. As usual, we have the following Corollary:

Corollary 5.7. For all $\epsilon \in (\mathbb{Z}/p\mathbb{Z})^*$, the space $S_{(2,2)}(\Gamma_{\infty,\epsilon}(p))$ is a free module of rank one over $\mathbf{T}_{(2,2)^*}(p)$. 

Proof. This follows from Theorem 5.4 and Proposition 2.7. \thickbox

We also have the following slight strengthening of Lemma 5.1:

Corollary 5.8. For every eigenform $f \in \mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$ there exists an eigenform $\hat{f} \in \mathfrak{S}_k(\Gamma_{\infty}(N))$ such that $f_\epsilon = \hat{f}$. 

Proof. By Lemma 5.1, $\mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$ has a basis consisting of such eigenforms. Since the eigenspaces are one-dimensional, however, every eigenform must be a multiple of one of those basis elements. \thickbox

And, finally, we have the facts that $\mathfrak{S}_k(\Gamma_{\infty}(N))$ and $\mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$ are isomorphic as $\mathbf{T}_{\infty}(N)$-modules and a geometric consequence of that fact:

Corollary 5.9. For all $\epsilon \in (\mathbb{Z}/N\mathbb{Z})^*$, $\mathfrak{S}_k(\Gamma_{\infty,-1}(N))$ is isomorphic to $\mathfrak{K}_{k,\epsilon}(N) \oplus \mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$ as a module over $\mathbf{T}_{\infty}(N)$. 

Proof. By definition, $\mathfrak{S}_k(\Gamma_{\infty,-1}(N)) = \mathfrak{K}_{k,\epsilon}(N) \oplus \mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$. But $\mathfrak{K}_{k,\epsilon}(N)$ is a $\mathbf{T}_{\infty}(N)$-module that is a direct sum of one-dimensional spaces corresponding to the Hecke eigenvalues occurring in $\mathfrak{S}_k(\Gamma_{\infty,\epsilon}(N))$; the Corollary then follows from Theorem 5.6. \thickbox

Corollary 5.10. If $N$ is a power of a prime then the geometric genus of (a desingularization of) $X_{\infty,\epsilon}(N)$ is maximized when $\epsilon = -1$. 

Proof. Corollary 2.3 and Proposition 2.8 allow us to reduce this Corollary to showing that, for all $\epsilon$ and for all $M|N$, the dimension of $S_{(2,2)}(\Gamma_{\infty,-1}(M))$ is at least as large as the dimension of $S_{(2,2)}(\Gamma_{\infty,\epsilon}(M))$. This in turn follows directly from the above Corollary. \thickbox

This Corollary is in fact true for all $N \leq 30$, as can be seen by examining the tables in Kani and Schanz [1]. Conjecture 2.6 would imply this Corollary for all natural numbers $N$, since in that case Proposition 2.8 would be true for all $N$. 

18
6 The Hecke Kernel

In the previous Section, we saw that, for all \( \epsilon \in (\mathbb{Z}/N\mathbb{Z})^* \), we can write \( \mathcal{S}_k(\Gamma_{\infty,-1}(N)) \) as \( \mathcal{K}_{k,\epsilon}(N) \oplus \mathcal{S}_k(\Gamma_{\infty,\epsilon}(N)) \). Thus, the key to understanding modular forms in all of the \( \mathcal{S}_k(\Gamma_{\infty,\epsilon}(N)) \)'s is to understand the space \( \mathcal{S}_k(\Gamma_{\infty,-1}(N)) \); once we have that, we then need to understand its subspaces \( \mathcal{K}_{k,\epsilon}(N) \). The goal of the present section is to study those subspaces, which we call “Hecke kernels”.

Note that Corollary 5.10 gives us a geometric interpretation of these spaces in some situations.

We first give the alternate following characterizations of forms in \( \mathcal{K}_{k,\epsilon}(N) \):

**Proposition 6.1.** Let \( f \) be an eigenform in \( \mathcal{S}_k(\Gamma_{\infty,-1}(N)) \) and let \( \epsilon \) be an element of \( (\mathbb{Z}/N\mathbb{Z})^* \).

The following are equivalent:

1. \( f \) is in \( \mathcal{K}_{k,\epsilon}(N) \).
2. For any or all eigenforms \( f \in \mathcal{S}_{k,\epsilon}(N) \) such that \( f_{-1} = f \), \( f_\epsilon = 0 \).
3. For all \( n_1, n_2 \) such that \( cn_1 + n_2 \equiv 0 \pmod{N} \), \( T_{n_1,n_2}f = 0 \).
4. For all \( m_1, m_2, n_1, n_2 \) with \( n_1m_1 \equiv n_2m_2 \pmod{N} \), \( cn_1 + n_2 \equiv 0 \pmod{N} \), and \((n_i, m_i) = 1 \) for \( i \in \{1, 2\} \), we have \( c_{n_1,n_2}(f) = 0 \).

**Proof.** We can assume \( f \) is a normalized eigenform. First we, show the equivalence between 1 and 2: let \( f \) be an eigenform in \( \mathcal{S}_k(\Gamma_{\infty}(N)) \) such that \( f_{-1} = f \), which we can find by Corollary 5.3. By Theorem 6.1, \( f \) only depends on the choice of \( f \) up to a non-zero constant multiple. If \( f_\epsilon \neq 0 \) then \( f \) is an eigenform in \( \mathcal{S}_k(\Gamma_{\infty,\epsilon}(N)) \) whose eigenvalues are the same as those of \( f \), hence are the same as the Fourier coefficients of \( f \), so \( f \) isn’t in \( \mathcal{K}_{k,\epsilon}(N) \). Conversely, if \( f \) isn’t in \( \mathcal{K}_{k,\epsilon}(N) \) then there exists an eigenform \( g \in \mathcal{S}_k(\Gamma_{\infty,\epsilon}(N)) \) whose eigenvalues are the Fourier coefficients of \( f \).

Corollary 5.8 allows us to pick an eigenform \( g \in \mathcal{S}_{k,\epsilon}(N) \) such that \( g_{\epsilon} = g \); multiplying it (and \( g \)) by a constant factor, we can assume that \( g \) is a normalized eigenform. Then \( g \) and \( g_{-1} \) have the same eigenvalues, so \( g_{-1} \) is a multiple of \( f \), by our assumption on \( g \); \( g \) therefore gives us an eigenform in \( \mathcal{S}_{k,\epsilon}(N) \) such that \( g_{-1} = f \) and \( g_{\epsilon} \neq 0 \), as desired. By Theorem 6.3, this is independent of the choice of \( g \), justifying our use of the phrase “any or all”.

Next we show that 2 and 3 are equivalent. Thus, we are given normalized eigenforms \( f \in \mathcal{S}_k(\Gamma_{\infty,-1}(N)) \) and \( \tilde{f} \in \mathcal{S}_k(\Gamma_{\infty}(N)) \) such that \( f = \tilde{f}_{-1} \) and we want to show that \( \tilde{f}_\epsilon = 0 \) if, for all \( n_1 \) and \( n_2 \) such that \( cn_1 + n_2 \equiv 0 \pmod{N} \), \( T_{n_1,n_2}f = 0 \). First assume that \( f_\epsilon = 0 \). By Lemma 5.3, \( f_1/\epsilon = 0 \). Then for all \( n_i \) as above,

\[
T_{n_1,n_2}f = T_{n_1,n_2}(f_{-1}) = (T_{n_1,n_2}f)_{-n_1/n_2} = (T_{n_1,n_2}f)_{1/\epsilon} = \lambda_{n_1,n_2}(f)f_{1/\epsilon} = 0.
\]

Conversely, if \( T_{n_1,n_2}f = 0 \) for all \( n_i \) with \( cn_1 + n_2 \equiv 0 \pmod{N} \) then the above series of equalities shows that \( \lambda_{n_1,n_2}(f)f_{1/\epsilon} \) is always zero, or equivalently (by Corollary 5.7), \( c_{n_1,n_2}(f)f_{1/\epsilon} = 0 \). If \( f_\epsilon \neq 0 \) then there exist such \( n_i \) such that \( c_{n_1,n_2}(f) \neq 0 \); thus, \( f_{1/\epsilon} = 0 \), so \( f_\epsilon \) is zero after all, by Lemma 5.3.

Next we show that 3 implies 4. Assume that, for all \( n_1 \) and \( n_2 \) with \( cn_1 + n_2 \equiv 0 \pmod{N} \), \( T_{n_1,n_2}f = 0 \). Then, for all \( m_1 \) and \( m_2 \) with \( (m_i, n_i) = 1 \), we have \( T_{m_1,n_2}(f) = T_{m_1,m_2}(T_{n_1,n_2}(f)) = 0 \), so in particular that is true for \( m_i \) with \( (m_i, n_i) = 1 \) and with \( m_1n_1 \equiv m_2n_2 \pmod{N} \). But Corollary 3.4 then implies that \( c_{m_1,n_2}(f) = 0 \).
Finally, we show that 4 implies 2, so let \( f \) be a normalized eigenform such that all such coefficients \( c_{m_1 n_1, m_2 n_2}(f) \) are zero, and let \( f \in \overline{S}_{k, \infty}(N) \) be a lift of \( f \). Assume that \( f_\ell \neq 0 \). Thus, there exist \( n_1 \) and \( n_2 \) with \( c_{n_1 n_2}(f) \neq 0 \), or, equivalently, \( \lambda_{n_1 n_2}(f) \neq 0 \). Then for all \( m_1 \) and \( m_2 \) with \( (m_i, n_i) = 1 \) and with \( m_1 n_1 \equiv m_2 n_2 \pmod{N} \), or equivalently \((1/\ell) m_1 + m_2 \equiv 0 \pmod{N} \),
\[
0 = \lambda_{m_1 n_1, m_2 n_2}(f) = \lambda_{m_1, m_2}(f) \lambda_{n_1, n_2}(f),
\]
so \( \lambda_{m_1, m_2}(f) = 0 \) for all \( m_i \) with \( (m_i, n_i) = 1 \) and \((1/\ell) m_1 + m_2 \equiv 0 \pmod{N} \). By Lemma \[1.4\], \( f_1/\ell = 0 \); by Lemma \[3.3\], \( f_\ell = 0 \), a contradiction. Thus 4 implies 2. \( \square \)

For an arbitrary form in \( \overline{K}_{k, \ell}(N) \), it is necessary for those coefficients specified in part 4 of Proposition \[3.3\] to vanish. The following Proposition shows that even more coefficients of elements of \( \overline{K}_{k, \ell}(N) \) vanish:

**Proposition 6.2.** For all \( a \) and \( \ell \) in \((\mathbb{Z}/N\mathbb{Z})^* \), the spaces \( \overline{K}_{k, \ell}(N) \) and \( \overline{K}_{k, a^2 \ell}(N) \) are equal.

**Proof.** Let \( f \) be an eigenform in \( \overline{K}_{k, \ell}(N) \); we want to show that \( f \) is in \( \overline{K}_{k, a^2 \ell}(N) \). Let \( f \) be a lift of it to \( \overline{S}_{k, \infty}(N) \). By Proposition \[1.4\], \( f_\ell = 0 \). Thus, \((a^{-1}) f\ell = (a^{-1})(f)\ell\) is also zero. But by Proposition \[1.4\], \((a^{-1}) f\ell = (a^{-1}) f\ell \) is non-zero since \((a^{-1}) f\ell \) is invertible. Thus, \( f_{a^2 \ell} = 0 \), so \( f \) is in \( \overline{K}_{k, a^2 \ell}(N) \), by Proposition \[3.3\]. \( \square \)

Thus, if \( f \in \overline{S}_{k, \infty}(N) \) is a normalized eigenform such that \( f_\ell = 0 \) for some \( \ell \), or equivalently that \( f_{a \ell} \) is an element of \( \overline{K}_{k, \ell}(N) \), then \( f_{a \ell} \) is also zero for all \( a \in (\mathbb{Z}/N\mathbb{Z})^* \). So if we let \( f = \sum \lambda f \) then lots of the Fourier coefficients of \( f \) are zero. This leads one to suspect that \( f \) might be related to forms with complex multiplication, where we define an eigenform \( g \) on \( X_w(N) \) to have complex multiplication if there exists a non-trivial character \( \phi \) such that \( \phi(p) \lambda_p(g) = \lambda_p(g) \) (or, equivalently, \( \lambda_p(g) = 0 \) unless \( \phi(p) = 1 \)) for all primes \( p \) in a set of density one, where \( \lambda_p(g) \) is the \( T_p \)-eigenvalue for \( g \). (This is as in Ribet [10], §3, except that we don’t require \( g \) to be a newform.) We also say that \( g \) is a CM-form. It is indeed the case that such forms are linked to elements of the Hecke kernel:

**Theorem 6.3.** An eigenform \( f \) is in \( \overline{K}_{(k_1, k_2), \ell}(N) \) if and only if there exist eigenforms \( f_i \in S_{k_i}(\Gamma_w(N)) \) such that, for all \( n_1 \equiv n_2 \pmod{N} \) with \( (n_i, N) = 1 \),
\[
c_{n_1, n_2}(f) = c_{n_1}(f_1) c_{n_2}(f_2)
\]
and such that the \( f_i \) have complex multiplication by some character \( \phi \) such that \( \phi(-\ell) = -1 \). Furthermore, \( \overline{K}_{(k_1, k_2), \ell}(N) \) is spanned by such forms.

**Proof.** Let \( k = (k_1, k_2) \), and let \( f \in \overline{S}_k(\Gamma_{w, \ell}(N)) \) be an eigenform. Pick an eigenform \( f \in \overline{S}_{k, \infty}(N) \) such that \( f_{-1} = f \) and let \( H \) be the subgroup of \( e' \in (\mathbb{Z}/N\mathbb{Z})^* \) such that \( f_{-e'} \neq 0 \), as in Theorem \[5.3\]. By Proposition \[4.4\] \( \sum f \) is an eigenform in \( \overline{S}_{k, \ell}(\Gamma_w(N)) \otimes \overline{S}_{k, \ell}(\Gamma_w(N)) \); eigenspaces in that latter space are one-dimensional, so \( \sum f = f_1 \otimes f_2 \), where \( f_i \in \overline{S}_{k_i}(\Gamma_w(N)) \) is an eigenform. We wish to relate \( f' \)'s being an element of \( \overline{K}_{k, \ell}(N) \), i.e. having \( f_\ell = 0 \), to the \( f_i \)’s being CM-forms.

For all \( m_1 \) and \( m_2 \) with \( (m_i, N) = 1 \), \( c_{m_1, m_2}(f) = c_{m_1}(f_1)c_{m_2}(f_2) \). If \( e \not\equiv H \), i.e. \( f_{-e'} = 0 \), then, for all \( m_i \) such that \( e' m_1 \equiv m_2 \pmod{N} \), \( c_{m_1, m_2}(f) = 0 \), so \( c_{m_1}(f_1) = 0 \) or \( c_{m_2}(f_2) = 0 \). Since the \( f_i \) are eigenforms, their first Fourier coefficients are non-zero; thus, setting \( m_2 = 1 \), \( c_{m_1}(f_1) = 0 \) for \( m_1 \equiv 1/e' \pmod{N} \) where \( e' \not\equiv H \). Since \( H \) is a subgroup, this means that \( c_{m_1}(f_1) = 0 \) for \( m_1 \not\equiv H \) (identifying \( m_1 \) with its projection to an element of \( (\mathbb{Z}/N\mathbb{Z})^* \)). Similarly, \( c_{m_2}(f_2) = 0 \) for \( m_2 \not\equiv H \).
First, assume that \( f \in \mathcal{T}_{k,\epsilon}(N) \), i.e. that \( f_e = 0 \), or that \( -\epsilon \notin H \). Pick a non-trivial character \( \phi \) of \((\mathbb{Z}/N\mathbb{Z})^*\) that is trivial on \( H \) and such that \( \phi(\epsilon) \neq -1 \). The previous paragraph shows that \( f_1 \) and \( f_2 \) both have complex multiplication by \( \phi \). By part 3 of Theorem 5.3 \( \phi \) has order two; thus, \( \phi(-\epsilon) = 1 \), as desired.

Conversely, assume that there exists a character \( \phi \) such that the forms \( f_1 \) have complex multiplication by \( \phi \) and such that \( \phi(-\epsilon) = 1 \). Pick \( m_1 \) and \( m_2 \) such that \( cm_1 + m_2 \equiv 0 \pmod{N} \). Then \( -\epsilon \equiv m_2/m_1 \pmod{N} \); since \( \phi(-\epsilon) = 1 \), either \( \phi(m_1) \) or \( \phi(m_2) \) is not equal to one. Thus, either \( c_m(f_1) \) or \( c_m(f_2) \) is zero, so \( c_m(f) = 0 \). This is true for all such \( m_1 \), so \( f_e = 0 \), i.e. \( f \in \mathcal{T}_{k,\epsilon}(N) \).

Finally, the fact that \( \mathcal{T}_{k,\epsilon}(N) \) is spanned by such forms follows from the fact that it has a basis of eigenforms, which is obvious from the definition of \( \mathcal{T}_{k,\epsilon}(N) \).

For \( p \) prime we define \( \mathcal{K}_{\pm}(p) \) to be the subspace \( \mathcal{T}_{(2,2),\epsilon}(p) \) of \( S_{(2,2)}(\Gamma_{\pm,\epsilon}(p)) \) for any \( \epsilon \in (\mathbb{Z}/p\mathbb{Z})^* \) such that \( -\epsilon \) is not square, where we identify \( S_{(2,2)}(\Gamma_{\pm,\epsilon}(p)) \) with \( \mathcal{T}_{(2,2)}(\Gamma_{\pm,\epsilon}(p)) \) by Proposition 2.7. (For this to make sense, we should assume that \( p \neq 2 \); since \( S_{(2,2)}(\Gamma_{\pm,\epsilon}(2)) \) is trivial for all \( \epsilon \), this isn’t very important.) This is independent of the choice of \( \epsilon \) by Proposition 6.2; its dimension is the difference between the geometric genera of \( X_{\pm,1}(p) \) and \( X_{\pm,\epsilon}(p) \), by Corollary 5.10. We shall give an explicit basis for this space in Sections 8 and 9.

7 The Adelic Point of View

As we have seen in Section 4, to get a satisfactory theory of Hecke operators, we had to consider the surface \( X_{\pm}(N) \), not just the surfaces \( X_{\pm,\epsilon}(N) \). To explain this, it helps to look at \( X_{\pm}(N) \) from the adelic point of view. Thus, we review some of definitions from that theory and explain their relevance to our context. For references, see Diamond and Im [3], Section 11.

Let \( \mathcal{A}^\infty \) denote the finite adeles, i.e. the restricted direct product of the fields \( \mathbb{Q}_p \) with respect to the rings \( \mathbb{Z}_p \). Let \( U \) be an open compact subgroup of \( \text{GL}_2(\mathcal{A}^\infty) \). We define the curve \( Y_U \) to be \( \text{GL}_2^+(\mathbb{Q}) \setminus \mathcal{A}^\infty / \mathcal{A}^\infty \). Here, \( \text{GL}_2^+(\mathbb{Q}) \) is the set of matrices in \( \text{GL}_2(\mathbb{Q}) \) with positive determinant, acting on \( \mathcal{A}^\infty \) via fractional linear translations and on \( \text{GL}_2(\mathcal{A}^\infty) \) via the injection \( \mathbb{Q} \to \mathcal{A}^\infty ; U \) acts trivially on \( \mathcal{A}^\infty \) and acts on \( \text{GL}_2(\mathcal{A}^\infty) \) via multiplication on the right. This defines \( Y_U \) as a non-compact curve over the complex numbers; it has a canonical compactification \( X_U \) given by adding a finite number of cusps. The curves \( X_U \) and \( Y_U \) in fact have canonical models over \( \mathbb{Q} \) which are irreducible; over \( \mathbb{C} \), however, the number of their components is given by the index of \( U \) in \( \tilde{\mathbb{Z}}^\times \). If \( U \) and \( U' \) are open compact subgroups of \( \text{GL}_2(\mathcal{A}^\infty) \) and if \( g \) is an element of \( \text{GL}_2(\mathcal{A}^\infty) \) such that \( g^{-1}Ug \subseteq U' \) then multiplication by \( g \) on the right gives a map \( g^*: X_U \to X_{U'} \); it descends to the models over \( \mathbb{Q} \).

We define a cusp form of weight \( k \) on \( X_U \) to be a function \( f : \mathcal{A}^\infty / \text{GL}_2(\mathcal{A}^\infty) \to \mathbb{C} \) such that

1. \( f(z, g) \) is a holomorphic function in \( z \) for fixed \( g \).
2. \( f(\gamma z, \gamma g) = j(\gamma, z)^k f(z, g) \) for all \( \gamma \in \text{GL}_2^+(\mathbb{Q}) \).
3. \( f(z, gu) = f(z, g) \) for all \( u \in U \).
4. \( f(z, g) \), considered as a function in \( z \), vanishes at infinity for all \( g \).

We denote by \( S_k(U) \) the space of all such forms. If \( g^{-1}Ug \subseteq U' \) then we get a map \( g_* : S_k(U') \to S_k(U) \) by defining \( (g_* f)(z, h) \) to be \( f(z, gh) \).

Each \( U \)-double coset in \( \text{GL}_2(\mathcal{A}^\infty) \) gives a Hecke operator, which acts on \( S_k(U) \). If \( U = \text{GL}_2(\mathbb{Z}_p) \times U^p \) then the Hecke operator \( T_p \) is generated by the elements of \( M_2(\mathbb{Z}_p) \) whose determinant is in
easy to check that the above definitions of Hecke operators pass over immediately to our situation; in particular, it is then recover our surfaces where \( GL_2(Z_p) \) is generated by \( T_p \) and \( S_p^{±1} \).

If we define \( S_k(C) \) to be the direct limit of the \( S_k(U) \)'s as \( U \) gets arbitrarily small then the above maps \( g_* \) make this into an admissible representation of \( GL_2(A^\infty) \); the original spaces \( S_k(U) \) can be recovered from that representation by taking its \( U \)-invariants. The main fact that we need is the following adelic analogue of parts of Atkin-Lehner theory:

**Theorem 7.1 (Strong Multiplicity One).** If \( \pi \) and \( \pi' \) are two irreducible constituents of \( S_k(C) \) such that \( \pi_p \) and \( \pi'_p \) are isomorphic for almost all \( p \) then \( \pi \) and \( \pi' \) are equal. (Not just isomorphic.) Furthermore, if \( f \) and \( f' \) are elements of \( \pi \) and \( \pi' \) then this is the case iff \( f \) and \( f' \) have the same eigenvalues for almost all \( T_p \) and \( S_p \); in this case, they have the same eigenvalues for all \( p \) such that \( f \in S_k(U) \) for some \( U \) of the form \( GL_2(Z_p) \times U_p \).

The subgroups that we shall be concerned with are

\[
U_w(N) = \left\{ g \in GL_2(\hat{Z}) \mid g \equiv \begin{pmatrix} * & 0 \\ 0 & 1 \end{pmatrix} \pmod{N} \right\}
\]

and

\[
U(N) = \left\{ g \in GL_2(\hat{Z}) \mid g \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \pmod{N} \right\}.
\]

These define the modular curves \( X_w(N) \) and \( X(N) \), respectively. The modular interpretation of \( X(N) \) is given as follows: for each \( \epsilon \in (Z/NZ)^* \), choose a matrix \( g_\epsilon \in GL_2(\hat{Z}) \) congruent to \( \begin{pmatrix} \epsilon^{-1} & 0 \\ 0 & 1 \end{pmatrix} \pmod{N} \). The strong approximation theorem for \( GL_2 \) implies that every point in \( Y(N) \) has a representative of the form \( (z, g_\epsilon) \) for some unique choice of \( \epsilon \); we let this point correspond to the elliptic curve \( C/(z, 1) \) together with the basis for its \( N \)-torsion given by \( (\epsilon z/N, 1/N) \). We then have an action of \( GL_2(Z/NZ) \) on \( X(N) \) that sends a matrix \( \tau \in GL_2(Z/NZ) \) to the map \( (g^{-1})^*: X(N) \to X(N) \), where \( g \) is any lifting of \( \tau \) to \( GL_2(\hat{Z}) \); it has the modular interpretation of preserving the elliptic curve and having \( \tau \) act on the basis for its \( N \)-torsion on the left.

Note that, in contrast, the action of \( SL_2(Z/NZ) \) on \( X_w(N) \) can't easily be defined adelically; this is one reason why one can't define such an action over \( Q \), and thus why we find it convenient to use the surfaces \( X(N) \) rather than \( X_w(N) \) at times. However, with a bit of care it is possible to use the action of \( GL_2(Z/NZ) \) on \( X(N) \) to extract information about the action of \( SL_2(Z/NZ) \) on \( X_w(N) \); we shall do this in Section 3.

Now we turn to the surfaces \( X_{\infty}(N) \). Definitions similar to the above go through, replacing \( \mathfrak{H} \times GL_2(A^\infty) \) by \( \mathfrak{H} \times GL_2(A^\infty) \times GL_2(A^\infty) \) and putting in two copies of everything else. We then recover our surfaces \( X_{\infty}(N) \) and spaces \( S_{k,\infty}(N) \) of cusp forms by using the following subgroup:

\[
U_{\infty}(N) = \left\{ (g_1, g_2) \in GL_2(\hat{Z}) \times GL_2(\hat{Z}) \mid g_1 \equiv g_2 \pmod{N} \right\}.
\]

The above definitions of Hecke operators pass over immediately to our situation; in particular, it is easy to check that \( T_{p_1, p_2} \) is \( T_{p_1} \times T_{p_2} \) (for \( (p, N) = 1 \) and \( (p) \) is \( 1 \times S_p \) (again for \( (p, N) = 1 \); note that \( S_p \times 1 \) is \( (p^{-1}) \)). Using these definitions, we also easily see that that, as claimed,

\[
X_{\infty}(N) = GL_2(Z/NZ) \setminus (X(N) \times X(N))
\]

where \( GL_2(Z/NZ) \) acts diagonally with the action given above.
In contrast with this situation, there does not exist a subgroup \( U_{z,e}(N) \) that would allow us to define \( X_{z,e}(N) \) in the same way; this explains why we couldn’t naturally define a Hecke operator \( T_{n_1,n_2} \) acting on \( X_{z,e}(N) \) unless \( n_1 \equiv n_2 \pmod{N} \). Of course, it isn’t hard to see which points on \( X_{z}(N) \) are on \( X_{z,e}(N) \) for some \( e \); they are the points that have a representative of the form \((z_1, z_2, g_1, g_2)\) with \( g_i \in \text{GL}_2(\mathbb{Z}) \) and with \( \det g_1 \equiv e \det g_2 \pmod{N} \). And if we are given \( f \in S_k(U_\infty(N)) = S_k(\Gamma_\infty(N)) \), we can recover \( f \), from it by letting
\[
f_e(z_1, z_2) = f(z_1, z_2, 1, g_e).
\]

8 The Case of Prime Level

In this Section, we discuss facts that are special to the case of weight \((2,2)\) forms on prime level. The main fact here is that we can ignore Fourier coefficients that are multiples of \( p \), as stated in Proposition \([4.2]\); this in turn implies that certain spaces of cusp forms are free of rank one over their Hecke algebras, as stated in Corollaries \([4.9, 5.7]\). In the rest of this Section, we shall present some general calculations that lead us towards methods for calculating the spaces \( S_{(2,2)}(\Gamma_{z,e}(p)) \); in the next Section, we shall give some explicit constructions of forms.

Since
\[
S_{(2,2)}(\Gamma_{z,e}(p)) = (S_2(\Gamma_w(p)) \otimes S_2(\Gamma_w(p)))^{	ext{SL}_2(\mathbb{Z}/p\mathbb{Z})},
\]
to understand \( S_{(2,2)}(\Gamma_{z,e}(p)) \) we should understand the representation theory of \( \text{SL}_2(\mathbb{Z}/p\mathbb{Z}) \) on \( S_2(\Gamma_w(p)) \). Since \((-1, 0, 0, 1)\) acts trivially on \( S_2(\Gamma_w(p)) \), we can look at the representation theory of \( \text{PSL}_2(\mathbb{F}_p) \) instead. We shall start by considering arbitrary weights and levels, and adding the assumptions of weight \( 2 \) and level \( p \) as it becomes convenient.

The basic fact about representations of groups on spaces of cusp forms is the Strong Multiplicity One Theorem. This tells us how to pick out the irreducible representations of \( \text{GL}_2(\mathbb{A}_\infty) \) that are contained in \( S_k(C) \): they are just the Hecke eigenspaces. Taking \( \text{GL}_2(\mathbb{Z}/N\mathbb{Z}) \)-invariants, this breaks up \( S_k(U(N)) \) into smaller subrepresentations of \( \text{GL}_2(\mathbb{Z}/N\mathbb{Z}) \). (Of course, these smaller subrepresentations may not be irreducible as representations of \( \text{GL}_2(\mathbb{Z}/N\mathbb{Z}) \).) To apply this, we need to relate \( S_k(U(N)) \) and its eigenspaces to spaces that we understand better.

First we recall that \( \left( \begin{array}{cc} N & 0 \\ 0 & 1 \end{array} \right)^{-1} \Gamma_w(N) \left( \begin{array}{cc} N & 0 \\ 0 & 1 \end{array} \right) \subset \Gamma_1(N^2) \). This allows us to pass from forms on \( X_w(N) \) to forms on \( X_1(N^2) \): the image of \( S_k(\Gamma_w(N)) \) is the direct sum of the spaces \( S_k(\Gamma_0(N^2), \chi) \) where \( \chi \) is a character on \( (\mathbb{Z}/N\mathbb{Z})^* \). A form \( f = \sum c_m q^m \), where \( q = e^{2\pi i \tau^{1/2}} \), gets sent to a form with the same Fourier expansion except that \( q \) is now equal to \( e^{2\pi i \tau^{1/2}} \). Furthermore, if \( \psi \) is a character on \( (\mathbb{Z}/N\mathbb{Z})^* \), then the form \( f_\psi \), which is defined to have Fourier expansion \( \sum c_m \psi(m) q^m \), is still a form in \( S_k(\Gamma_w(N)) \), by Shimura \([12]\), Proposition 3.64.

We now turn to producing forms contained in \( S_k(U(N)) \). A form \( f \in S_k(U(N)) \) is a function from \( \mathcal{D} \times \text{GL}_2(\mathbb{A}_\infty) \) to \( \mathbb{C} \) with those properties listed in Section \([3]\); it then follows easily that if, for \( \epsilon \in (\mathbb{Z}/N\mathbb{Z})^* \), we define \( f_\epsilon \) by setting \( f_\epsilon(z) = f(z, g_\epsilon) \) (where \( g_\epsilon \) is a matrix in \( \text{GL}_2(\mathbb{Z}) \) that is congruent to \( \left( \begin{array}{cc} -1 & q \\ 0 & 1 \end{array} \right) \) \( \pmod{N} \) then each of the \( f_\epsilon \)'s is a form in \( S_k(\Gamma_w(N)) \). By the Strong Approximation Theorem, a choice of such \( f_\epsilon \)'s determines \( f \) uniquely. Thus, we can think of forms on \( S_k(U(N)) \) as \( \phi(N) \)-tuples of forms on \( S_k(\Gamma_w(N)) \).

This allows us to determine the Hecke eigenspaces in \( S_k(U(N)) \). The dimension of \( S_k(U(N)) \) is \( \phi(N) \) times the dimension of \( S_k(\Gamma_w(N)) \), so the hope is that each eigenform on \( S_k(\Gamma_w(N)) \) will somehow give us \( \phi(N) \) different eigenforms on \( S_k(U(N)) \). This is indeed what happens, as we shall see in Proposition \([5.3]\)
Lemma 8.1. Let $\mathbf{f}$ be an element of $S_k(U(N))$ and let $q$ be a prime not dividing $N$. Then, for all $\epsilon \in (\mathbb{Z}/N\mathbb{Z})^*$, $(T_q \mathbf{f})_\epsilon = T_q (\mathbf{f}_q)$ and $(S_q \mathbf{f})_\epsilon = S_q (\mathbf{f}_q)$.

Proof. This follows from tracing through the definitions; alternately one can use the modular interpretation of points on $X(N)$ and Hecke operators together with the fact that if $\pi: E \to E'$ is an isogeny of degree $N$ then $(\pi x, \pi y)_{E'} = (x, y)_E^N$, where $(,)_E$ denotes the Weil pairing. \hfill \Box

Corollary 8.2. Let $g \in S_k(\Gamma_w(N))$ be an eigenform, with eigenvalues $\{a_q, \chi(q)\}$ (for $T_q$ and $S_q$ respectively, as $q$ varies over primes not dividing $N$). Let $\psi$ be a character of $(\mathbb{Z}/N\mathbb{Z})^*$. Then the form $\mathbf{f}(g, \psi) \in S_k(U(N))$ defined by $\mathbf{f}(g, \psi)_\epsilon = \psi(\epsilon)g$ is an eigenform with eigenvalues $\{\psi(q)a_q, \psi^2(q)\chi(q)\}$.

Proof. Write $\mathbf{f}$ for $\mathbf{f}(g, \psi)$. By the Lemma,

$$(T_q \mathbf{f})_\epsilon = T_q (\mathbf{f}_q) = T_q (\psi(q)g) = \psi(q)\psi(\epsilon)a_qg = \psi(q)a_q\mathbf{f}.$$ 

The calculation for $S_q$ proceeds in exactly the same manner. \hfill \Box

This allows us to produce a basis of eigenforms for $S_k(U(N))$ in terms of a basis of eigenforms for $S_k(\Gamma_w(N))$:

Proposition 8.3. Let $\{g_j\}$ be a basis of eigenforms for $S_k(\Gamma_w(N))$. Then the set of forms $\{\mathbf{f}(g_j, \psi)\}$, as $g_j$ varies over elements of the basis and $\psi$ varies over characters of $(\mathbb{Z}/N\mathbb{Z})^*$, give a basis of eigenforms for $S_k(U(N))$. Every set $\{a_q, \chi(q)\}$ of eigenvalues for $T_q$ and $S_q$ (as $q$ runs over primes not dividing $N$) that occurs in $S_k(U(N))$ occurs in $S_k(\Gamma_w(N))$. A basis for the set of eigenforms in $S_k(U(N))$ with eigenvalues $\{a_q, \chi(q)\}$ is given by taking the forms $\mathbf{f}(g, \psi)$ where $\psi$ varies over the characters of $(\mathbb{Z}/N\mathbb{Z})^*$ and where, once $\psi$ is fixed, $g$ varies over a basis for those eigenforms in $S_k(\Gamma_w(N))$ which have eigenvalues $\{a_q\psi^{-1}(q), \chi(q)\psi^{-2}(q)\}$.

Proof. Assume that we have an expression of linear dependence involving the forms $\mathbf{f}(g_j, \psi)$. Looking at the first coordinate, the fact that the forms $\{g_j\}$ form a basis for $S_k(\Gamma_w(N))$ implies that we can assume that our relation involves only forms $\mathbf{f}(g, \psi)$ for some fixed form $g$. But those forms are linearly independent since characters are linearly independent. This gives us $\phi(N) \cdot \dim S_k(\Gamma_w(N))$ forms; but that's the dimension of $S_k(U(N))$, so those forms give a basis for $S_k(U(N))$ that consists of eigenforms.

Every set of eigenvalues on $S_k(U(N))$ is therefore of the form $\{\psi(q)a_q, \psi^2(q)\chi(q)\}$, where $\{a_q, \chi(q)\}$ is the set of eigenvalues of a form $g \in S_k(\Gamma_w(N))$, by Corollary 8.2. But those are the eigenvalues of $g_\psi$, which is also an eigenform in $S_k(\Gamma_w(N))$. The last statement of the Proposition follows in a similarly direct manner from the first paragraph of the proof and Corollary 8.2. \hfill \Box

To restate the last sentence of the above Proposition: assume that $g \in S_k(\Gamma_w(N))$ is a newform with eigenvalues $\{a_p, \chi(p)\}$. A basis for the eigenforms in $S_k(U(N))$ with those eigenvalues is given by the forms $\mathbf{f}(g_\psi^{-1}, \psi)$ together with the forms $\mathbf{f}(h, \psi)$ where $h$ runs over oldforms with the same eigenvalues as $g_\psi^{-1}$.

Let us now fix $k = 2$ and $N = p$ prime. We may assume that $p > 5$, since $S_2(\Gamma_w(p))$ is zero otherwise. Pick a set $A = \{a_q, \chi(q)\}$ of eigenvalues. Let $g \in S_2(\Gamma_w(p))$ be a newform with those
eigenvalues; we wish to calculate the dimension of the space $S_A$ of forms in $S_2(\mathbb{U}(p))$ with eigenvalues $A$. For each character $\psi$, we can produce an element of $S_A$ all of whose components are multiples of $g_{\psi^{-1}}$; this gives us $(p-1)$ forms. Furthermore, when $g_{\psi^{-1}}$ is an oldform, we can produce extra forms. Since $S_2(\Gamma(1))$ is zero, we can produce at most one extra form for each $\psi$ this way: this happens when the eigenvalues $\{a_q\psi^{-1}(g), \chi(q)\psi^{-2}(g)\}$ occur in $S_2(\Gamma_1(p))$.

For how many $\psi$ does an extra form arise in this way? By the Strong Multiplicity one theorem, studying $S_A$ reduces to the study of irreducible representations of $GL_2(\mathbb{A}^\infty)$ and their $U(p)$-invariants. Factoring those representations, we have to study irreducible representations of $GL_2(\mathbb{Q}_q)$ and their $U(p)_q$-invariants. If $q \neq p$ then $U(p)_q = GL_2(\mathbb{Z}_q)$; since the space of $GL_2(\mathbb{Z}_q)$ invariants of an irreducible representation of $GL_2(\mathbb{Q}_q)$ is either zero- or one-dimensional, we can therefore concentrate on the irreducible representations of $GL_2(\mathbb{Q}_p)$, and in particular calculating the dimension of their $U(p)_p$-invariants, where

$$U(p)_p = \left\{ g \in GL_2(\mathbb{Z}_p) \mid g \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \pmod{p} \right\}.$$ 

Irreducible representations of $GL_2(\mathbb{Q}_p)$ can be classified as principal series, special, or supercuspidal. If the space of $U(p)_p$-invariants is nonzero then it is $(p+1)$-, $p$-, or $(p-1)$-dimensional, depending on which classification it falls into; thus, we have two, one, or no extra dimensions of oldforms arising in the principal series, special, and supercuspidal cases, respectively.

Let us now turn towards the space $S_2(\Gamma_w(p))$. The group $PSL_2(\mathbb{F}_p)$ acts on this space; we wish to determine its irreducible representations. Since this action is not given adelicly, we can’t just apply the theory of irreducible $GL_2(\mathbb{A}^\infty)$-representations and the Strong Multiplicity One Theorem to get the answer. However, we can use the adelic action to get information about this representation as follows: let $g$ be an element of $S_2(\Gamma_w(p))$ and let $f$ be an element of $S_2(\mathbb{U}(p))$ such that $f_1 = g$. Let $\varpi$ be an element of $PSL_2(\mathbb{F}_p)$ and let $\gamma$ be an element of $GL_2(\mathbb{Z}_p)$ projecting to it. Then $\varpi$ sends $g$ to $(\gamma^{-1} g)_1$, as can be seen by tracing through the definitions. In particular, we get representations of $PSL_2(\mathbb{F}_p)$ on $S_2(\Gamma_w(p))$ by projecting the representations given in the previous paragraphs down to their first coordinate.

The map from $S_2(\mathbb{U}(p))$ to $S_2(\Gamma_w(p))$ sending $f$ to $f_1$ is injective unless there is a $\psi$ such that $g = g_{\psi}$, by Proposition 8.3, i.e. unless $g$ is a CM-form, in which case all of the forms in the representation are CM-forms, and the dimension of the representation in $S_2(\Gamma_w(p))$ is half of the dimension of the representation in $S_2(\mathbb{U}(p))$. Thus, we have decomposed $S_2(\Gamma_w(p))$ as a direct sum of representations that are either of dimension $p-1$, $p$, $p+1$, $(p-1)/2$, or $(p+1)/2$.

These representations may not be irreducible, however. Most of the time, they do turn out to be irreducible; we can see this by looking at the character table of $PSL_2(\mathbb{F}_p)$. The dimensions of the irreducible representations of $PSL_2(\mathbb{F}_p)$ are 1, $p-1$, $p$, $p+1$, and either $(p-1)/2$ (if $p \equiv 3 \pmod{4}$) or $(p+1)/2$ (if $p \equiv 1 \pmod{4}$). Furthermore, the only one-dimensional representation of $PSL_2(\mathbb{F}_p)$ is the trivial one, which doesn’t occur in $S_2(\Gamma_w(p))$ (since that would be equivalent to having a form that is invariant under $PSL_2(\mathbb{F}_p)$, i.e. a form in $S_2(\Gamma(1))$). There are no 2-dimensional representations, either, so by comparing dimensions, we see that the representations that we have constructed above are either trivial or the direct sum of two representations of dimension $(p-1)/2$ or $(p+1)/2$.

We wish to see how $\dim S_{(2,2)}(\Gamma_w,\epsilon(p))$ varies as a function of $\epsilon$. Write $\chi_w(p)$ for the character
of $S_2(\Gamma_w(p))$, considered as a representation of $\text{PSL}_2(\mathbb{F}_p)$. Then
\begin{align*}
\dim S_{(2,2)}(\Gamma_{\pm,c}(p)) &= \dim(S_2(\Gamma_w(p)) \otimes S_2(\Gamma_w(p)) \circ \theta_c)^{\text{PSL}_2(\mathbb{F}_p)} \\
&= \langle \chi_w(p) \otimes \chi_w(p) \circ \theta_c, 1 \rangle \\
&= \langle \chi_w(p), \chi_w(p) \circ \theta_c \rangle.
\end{align*}

Assume that $S_2(\Gamma_w(p))$ has $\bigoplus_i R_i^{\oplus n_i}$ as its decomposition into a sum of irreducible representations. Then, by the above,
\[\dim S_{(2,2)}(\Gamma_{\pm,c}(p)) = \sum_{i,j} n_in_j.\]

Now assume that $p \equiv 1 \pmod{4}$. Examining the character table of $\text{PSL}_2(\mathbb{F}_p)$, we see that $R_i \cong \overline{R_i}$ for all $R_i$ and that $R_i \cong R_i \circ \theta_2$ for all $\epsilon$ unless $R_i \cong W'$ or $W''$, where $W'$ and $W''$ are the irreducible representations of dimension $(p+1)/2$. In this latter case, composing with $\theta_2$ switches $W'$ and $W''$ if $\epsilon$ is not a square. Now assume that $W'$ occurs $n'$ times in the decomposition of $S_2(\Gamma_w(p))$ and $W''$ occurs $n''$ times. Then, if $\epsilon_1$ is a square and $\epsilon_2$ isn’t, the above discussion shows that
\[\dim S_{(2,2)}(\Gamma_{\pm,\epsilon_1}(p)) - \dim S_{(2,2)}(\Gamma_{\pm,\epsilon_2}(p)) = n'^2 + n''^2 - 2n'n'' = (n' - n'')^2.\]

This is a bit misleading, however, because in this case $n'$ and $n''$ are equal, so the dimension of $S_{(2,2)}(\Gamma_{\pm,\epsilon}(p))$ is the same for all $\epsilon$. We can see this by calculating $n'$ and $n''$ using Ligozat's Proposition II.1.3.2.1: the characters of $W'$ and $W''$ only differ in matrices that are conjugate to $\left( \begin{smallmatrix} 1 & a \\ 0 & 1 \end{smallmatrix} \right)$, and the only place that such matrices occur in the formula given there is in the term $\sum_a \chi(\left( \begin{smallmatrix} 1 & a \\ 0 & 1 \end{smallmatrix} \right))$, which equals $(p + 1)/2$ both for $\chi = \chi_{W'}$ and $\chi = \chi_{W''}$.

As a corollary, this implies that there are no CM-forms in $S_2(\Gamma_w(p))$ for $p \equiv 1 \pmod{4}$. If there were such a form $g$, it would generate an irreducible representation $R_g \subset S_2(\Gamma_w(p))$, all of whose elements would be CM-forms; there would then be a form in $R_g \otimes (R_g \circ \theta_{-1})$ that is invariant under $\text{PSL}_2(\mathbb{F}_p)$. But such a form would be a CM-form in $S_{(2,2)}(\Gamma_{\pm,-1}(p))$, so Theorem 5.3 would then imply that the dimension of $S_{(2,2)}(\Gamma_{\pm,\epsilon}(p))$ for $\epsilon$ a non-square is strictly smaller than the dimension of $S_{(2,2)}(\Gamma_{\pm,-1}(p))$, contradicting our calculations above.

Let us now turn to the case where $p \equiv 3 \pmod{4}$. This time, $R_i \cong \overline{R_i}$ unless $R_i \cong X'$ or $X''$, where $X'$ and $X''$ are the irreducible representations of dimension $(p-1)/2$; $X'$ and $X''$ and vice-versa. Similarly, $R_i \circ \theta_{-2} \cong R_i$, unless $R_i \cong X'$ or $X''$ and $\epsilon$ is not a square mod $p$; if it is, $X' \circ \theta_{-2} \cong X''$ and vice-versa. Thus, if $X'$ occurs $n'$ times and $X''$ occurs $n''$ times in the decomposition of $S_2(\Gamma_w(p))$,
\begin{align*}
\dim S_{(2,2)}(\Gamma_{\pm,\epsilon_1}(p)) - \dim S_{(2,2)}(\Gamma_{\pm,\epsilon_2}(p)) &= 2n'n'' - (n'^2 + n''^2) \\
&= -(n' - n'')^2,
\end{align*}
where $\epsilon_1$ is a square mod $p$ and $\epsilon_2$ isn’t. Since $-1$ is not a square, the dimension is maximized when $\epsilon = -1$, agreeing with Corollary 5.10.

This time, however, $n' - n''$ is non-zero. We can’t calculate it as easily as we calculated it in the previous case, because the method used there calculates the number of times a representation occurs plus the number of times that its complex conjugate occurs, and here the character is no
longer totally real. Instead, we refer to Hecke \[3\], where he proves that the difference is equal to the class number \(h(-p)\) of \(\mathbb{Q}(\sqrt{-p})\). Thus,

\[
\dim S_{(2,2)}(\Gamma_{\zeta,-1}(p)) - \dim S_{(2,2)}(\Gamma_{\zeta,1}(p)) = h(-p)^2.
\]

As before, this implies that there are exactly \(h(-p) \cdot (p - 1)/2\) CM-forms contained in \(S_2(\Gamma_w(p))\); they have been constructed by Hecke in \[3\]. We shall review his construction in Section 9, and use them to write down the Hecke kernel \(K_{\zeta}(p)\) explicitly. We shall also show how to use the theory outlined in this Section to perform explicit calculations of spaces \(S_{(2,2)}(\Gamma_{\zeta,\epsilon}(p))\) for small primes.

To recap:

**Theorem 8.4.** If \(p\) is a prime congruent to 1 mod 4 then there are no CM-forms contained in \(S_2(\Gamma_w(p))\) and the Hecke kernel \(K_{\zeta}(p)\) is zero. If \(p > 3\) is congruent to 3 mod 4 then there are \(h(-p) \cdot (p - 1)/2\) CM-forms contained in \(S_2(\Gamma_w(p))\) and \(K_{\zeta}(p)\) has dimension \((h(-p))^2\), where \(h(-p)\) is the class number of \(\mathbb{Q}(\sqrt{-p})\).

\[\square\]

### 9 Examples

**\(X_{\zeta,-1}(7)\)**

The first \(X_{\zeta,\epsilon}(p)\) to have a non-zero \((2,2)\)-cusp form is \(X_{\zeta,-1}(7)\), as can be seen by looking at Table 1 in Kani and Schanz \[7\] (and using Corollary 2.3 above); in fact, we see that \(\dim S_{(2,2)}(\Gamma_{\zeta,-1}(7)) = 1\). We can explicitly determine a non-zero form in this space as follows:

Conjugating \(\Gamma_w(7)\) by \((\frac{7}{0},\frac{0}{7})\), we can think of \(X_w(7)\) as lying between the curves \(X_0(49)\) and \(X_1(49)\). The former is an elliptic curve (after choosing a base point); its L-series gives rise to a weight two cusp form

\[
f(z) = \sum_{m>0} c_m q^m
\]

on \(X_0(49)\) and \(X_w(7)\). (Here, \(q = e^{2\pi i z}\) if we are thinking of \(f\) as a form on \(X_0(49)\) and \(q = e^{2\pi i z/7}\) if we are thinking of \(f\) as a form on \(X_w(7)\).) If \(\chi\) is a non-trivial character on \((\mathbb{Z}/7\mathbb{Z})^*\) such that \(\chi(-1) = 1\) then the functions

\[
f_\chi(z) = \sum_{m>0} c_m \chi(m) q^m
\]

and

\[
f_{\chi^2}(z) = \sum_{m>0} c_m \chi^2(m) q^m
\]

are also modular forms in \(S_2(\Gamma_w(7))\), by Shimura \[12\], Proposition 3.64; since the latter space is three-dimensional, \(\{f, f_\chi, f_{\chi^2}\}\) forms a basis for it. For \(n \in (\mathbb{Z}/7\mathbb{Z})^*\), we have \(f_\chi|_{\sigma_a} = \chi^2(a) f_\chi\) and \(f_{\chi^2}|_{\sigma_a} = \chi(a) f_{\chi^2}\).

To produce an element of \(S_{(2,2)}(\Gamma_{\zeta,-1}(7))\), we have to find a form contained in \(S_2(\Gamma_w(7)) \otimes S_2(\Gamma_w(7))\) that is fixed by \(\text{PSL}_2(\mathbb{F}_7)\) (acting on the second factor via \(\theta_{-1}\)). For our form to be fixed by the matrices \((\sigma_a, \sigma_a)\), it has to be of the form

\[a_0 \cdot f \otimes f + a_1 \cdot f_\chi \otimes f_{\chi^2} + a_2 \cdot f_{\chi^2} \otimes f_\chi.\]
And for our form to be fixed by the matrix \( \left( \begin{array}{cc} 1 & 1 \\ -1 & 1 \end{array} \right), \left( \begin{array}{cc} 1 & 1 \\ 1 & 1 \end{array} \right) \), we must have \( a_0 = a_1 = a_2 \). However, those constraints leave us with only a one-dimensional space of possible cusp forms, and since \( S_{(2,2)}(\Gamma_{\pm,1}(7)) \) is non-empty, we see that it must be generated by the form

\[
g = \frac{1}{3} (f \otimes f + f_X \otimes f_X^2 + f_X^2 \otimes f_X) = \sum_{m_1 \equiv m_2 (\text{mod } 7)} c_{m_1} c_{m_2} q_1^{m_1} q_2^{m_2},
\]

where the \( c_i \)'s are the coefficients of \( f \) as above.

Now that we’ve got our form \( g \) in hand, we’d like to relate it to some of our general theorems about forms in \( \mathbb{S}_k(\Gamma_{\pm,\epsilon}(N)) \). Note that \( g \) has lots of Fourier coefficients that are zero: not only is \( c_{m_1,m_2}(g) \) zero unless \( m_1 \equiv m_2 \) (mod 7), but it’s also zero unless the \( m_i \)'s are squares mod 7. (This follows from the fact that the elliptic curve \( X_0(49) \) has complex multiplication by \( \mathbb{Q}(\sqrt{-7}) \).) By Proposition 6.1, our form is therefore in \( K_\epsilon(7) \); indeed, \( S_{(2,2)}(\Gamma_{\pm,1}(7)) \) is trivial.

\( X_{\pm,-1}(p) \) for \( p \equiv 3 \) (mod 4)

The above may look like a general recipe for producing forms on \( X_{\pm,\epsilon}(p) \) out of forms on \( X_0(p^2) \), but it isn’t. To see why, note that the transition involved two steps: matching up characters, which involved checking invariance under the matrices \( (\sigma_\alpha, \sigma_\alpha) \), and making sure that certain Fourier coefficients were zero, which involved checking invariance under the matrices \( \left( \begin{array}{cc} 1 & 1 \\ 0 & 1 \end{array} \right) \). Thus, we checked that our putative form is invariant under the subgroup \( B(p) \) of upper-triangular matrices, not all of \( \mathrm{PSL}_2(\mathbb{F}_p) \). The reason why we could get away with that above was that we knew a lot about \( S_2(\Gamma_\epsilon(7)) \) and that the dimension of \( S_{(2,2)}(\Gamma_{\pm,1}(7)) \) was 1.

Fortunately, all is not lost for more general \( p \). Let \( R_1 \) and \( R_2 \) be an irreducible representation occurring in \( S_2(\Gamma_\epsilon(p)) \). As the discussion in Section 5 showed, \( R_1 \otimes R_2 \) contributes 1 to the dimension of \( S_{(2,2)}(\Gamma_{\pm,\epsilon}(p)) \) iff \( R_1 = R_2 \circ \theta_\epsilon \). Now, assume that that is indeed the case, and that, furthermore, \( R_1 \) is irreducible as a representation of \( B(p) \). Writing \( \chi_i \) for the character of \( R_i \), it will then also be the case that

\[
\langle \chi_1 \cdot (\chi_2 \circ \theta_\epsilon), 1_{B(p)} \rangle_{B(p)} = \langle \chi_1, \chi_2 \circ \theta_\epsilon \rangle_{B(p)} = 1.
\]

But this says that there’s only a one-dimensional space of vectors in \( R_1 \otimes R_2 \) that is fixed by \( B(p) \), and since there is also a one-dimensional space of vectors in \( R_1 \otimes R_2 \) that is fixed by \( \mathrm{PSL}_2(\mathbb{F}_p) \), they must be the same space. Thus, under the hypothesis that our representation is irreducible when considered as a representation of \( B(p) \), we can test to see whether an element of \( R_1 \otimes R_2 \) is a cusp form on \( X_{\pm,\epsilon}(p) \) simply by making sure that it is invariant under \( (\sigma_\alpha, \sigma_\alpha) \) and \( \left( \begin{array}{cc} 1 & 1 \\ 0 & 1 \end{array} \right) \).

To make this concrete, assume that \( p \) is congruent to 3 (mod 4) but not equal to 3 and that \( \epsilon = -1 \). The character table for \( \mathrm{PSL}_2(\mathbb{F}_p) \) is given in Section 5; checking the non-trivial characters listed there, we see that \( X' \) and \( X'' \) are irreducible when restricted to \( B(p) \). Thus, if we can produce representations isomorphic to \( X' \) or \( X'' \) in \( S_2(\Gamma_w(p)) \), we’ll be able to explicitly write down forms in \( S_{(2,2)}(\Gamma_{\pm,-1}(p)) \). We saw that there should be \( h(-p) \) such representations coming from CM-forms; they would be good ones to look for.

Fortunately, those representations are produced in Hecke 3. They are defined as follows: let \( I \) be an integral ideal in \( \mathbb{Q}(\sqrt{-p}) \) with norm \( A \) and let \( \rho \) be an element of \( I \). We define a theta series as follows:

\[
\theta_H(z; \rho, I, \sqrt{-p}) = \sum_{\mu \in I} \mu e^{2\pi i \sqrt{-p} \frac{z^2 \mu^2}{\rho}},
\]

\[
\mu \equiv \rho \text{ mod } I \sqrt{-p}
\]
where $\overline{\mu}$ is the complex conjugate of $\mu$. Letting $V_I$ be the vector space generated by the functions
\[ \theta_H(z; \rho, I, \sqrt{-p}) \]
for $\rho \in I$, the results of Hecke [3, §7] show that $V_I$ only depends on the ideal class of $I$, that these $\theta_H$’s are elements of $S_2(\Gamma_w(p))$, and that $V_I$ is a representation of $\text{PSL}_2(\mathbb{F}_p)$ isomorphic to $X'$. This gives us our desired $h(-p)$ different copies of $X'$.

Now that we have our representations, we follow the same program as in the $X_{\infty, -1}(7)$ case:

**Theorem 9.1.** Let $p$ be a prime congruent to 3 mod 4. For each ideal class of $\mathbb{Q}(\sqrt{-p})$, fix an integral ideal $I$ in that class and an element $\alpha_I$ of $I$ that’s not contained in $I\sqrt{-p}$. Let
\[ f_I = \sum_{a \in (\mathbb{Z}/p\mathbb{Z})^*} \theta_H(z; a\left(\frac{a}{p}\right) \alpha_I, I, \sqrt{-p}) \]
have the Fourier expansion
\[ f_I(z) = \sum_{m \geq 0} c_{I,m} q^m, \]
where $q = e^{2\pi \sqrt{-z/p}}$. If $I_1$ and $I_2$ are (not necessarily distinct) ideal classes then the function
\[ f_{I_1,I_2}(z_1, z_2) = \sum_{m_1 \equiv m_2 (\text{mod } p)} c_{I_1,m_1} c_{I_2,m_2} q_{1}^{m_1} q_{2}^{m_2}. \]
is an element of $S_{(2,2)}(\Gamma_{\infty,-1}(p))$ contained in $K_\infty(p)$; furthermore, the $f_{I_1,I_2}$’s give a basis for $K_\infty(p)$ as $I_1$ and $I_2$ vary over the ideal classes of $\mathbb{Q}(\sqrt{-p})$.

**Proof.** The same argument as in the $p = 7$ case shows that multiples of $f_{I_1,I_2}$ are the only elements of $V_{I_1} \otimes V_{I_2}$ invariant under $B(p)$, so they are indeed elements of $S_{(2,2)}(\Gamma_{\infty,-1}(p))$. Assuming that we can show that they are in $K_\infty(p)$, Theorem 6.4 shows that they give us a basis. Thus, by Theorem 8.3, we just have to verify that the forms $f_I$ are CM-forms.

This can be seen as follows: by definition,
\[ c_m(\theta_H(z; \rho, I, \sqrt{-p})) = \sum_{\mu \equiv l (\text{mod } I\sqrt{-p})} \mu, \]
where $A$ is the norm of $I$ But $\mu \overline{\mu}$ is a square mod $p$ for all $\mu$ in the ring of integers of $\mathbb{Q}(\sqrt{-p})$, as is $A$, so $c_m$ is zero unless $m$ is a square mod $p$. Thus, $f_I$ is invariant under twisting by the quadratic character of $(\mathbb{Z}/p\mathbb{Z})^*$, hence a CM-form.
