Abstract. Template assisted assembly of molecular nano arrays is one of the key steps towards molecular electronics and fullerene is one of the potential structural building blocks in fabrication of identical molecular nano arrays for miniature devices such as photovoltaic devices and single-molecule transistors. In this report, the reconstructed Au (111) with defect areas (steps) has been used as a template to assemble the highly ordered $C_{60}$ nano array at low coverage studied with scanning tunnelling microscopy (STM) in conjunction with density functional theory (DFT). The interaction between the substrate and $C_{60}$ nano arrays is strong enough to change the geometrical shape of $C_{60}$. As a result of strong interaction, the $C_{60}$ molecule appears to be deformed into ellipsoidal shape which causes the reduction of $C_{60}$ nano arrays on step sites of Au (111).

1. Introduction

Fullerene is one of the potential structural building blocks in fabrication of identical nano scale structures for miniature devices, such as photovoltaic devices and single-molecule transistors.[1] In addition to be a flexible building-block material, fullerenes are also a kind of electron acceptors that can offer an ease of fabrication of donor-acceptor nanojunctions.

Until now, the investigation of self-assembled structures of $C_{60}$ on flat metal surfaces has been focused on monolayer structures by many research groups. [2] To our knowledge, a few reports have been done on the investigation of adsorption behavior of $C_{60}$ residing on the step of vicinal metal surfaces which have been used as novel templates to prepare controllable nanostructures.[3] One big advantage of this method is that it can avoid introducing of impurities. Since no more experimental procedures are required, using vicinal gold templates saves much time than other methods as well.

Vicinal gold surfaces are useful for controlling the nano scale structure in specific energetic sites. One of the templates is Au (111) which has been studied extensively for the formation of 2 D arrays of metal islands. Adsorption of molecules occurs preferentially at defects such as step edges and kinks at room temperature. [4] For the adsorption of $C_{60}$ on Au (111) at room temperature, the molecules quickly move to the preferential adsorption sites (steps).

In this work, we found that there is an apparent shortening of $C_{60}$ arrays residing on linear steps of Au (111) by analyzing the line profile of STM topography. Our calculations using Density functional Theory (DFT) suggest that the shortening is due to the molecular distortions in the middle of arrays caused by the elongation of the C-C bond length and pit formation on the gold layer.
2. Experimental details

All experiments were carried out in an UHV chamber (base pressure \(< 10^{-10} \text{ mbar}\)) equipped with an Omicron LT-STM operated at 77K. A tungsten tip was used, and all STM measurements were performed in a constant-current mode. The Au (111) single-crystal substrate was cleaned by several cycles of Ar\(^+\) sputtering (U=1.0kV) and subsequent annealing (T=300°C for 5 minutes, measured by a thermocouple directly attached to the crystal). \(\text{C}_{60}\) was purchased from Sigma Aldrich and used without further purification. The \(\text{C}_{60}\) was sublimed at 650 K from crucible to Au (111) surface that was held at room temperature for 1 minute. STM images of interested surface areas are obtained at~77 K.

3. Results and discussion

It is necessary to determine the crystallographic features of Au (111) substrate used as a template for \(\text{C}_{60}\) growth before the study of the adsorption behavior of it. The Au (111) surface we choose is not only large area of terrace (50 %) but also linear steps (45 %) and kinks site (5 %). Even though, the substrate we choose is not a well prepared vicinal surface, some part of it is a good candidate as a natural template for growing of nano arrays. As a result of contraction in the [110] direction, the herringbone reconstruction forms. The reconstruction pattern can be seen in STM topography image of clean Au (111) surface in Fig. 1 (a).

![STM topography image of Au (111) at I\(_t\) = 20 nA, V\(_{\text{bias}}\) = 1 V](image)

After deposition of \(~0.05\) Mono Layer (ML) (1 ML corresponds to a closed pack full coverage of molecules on the surface) molecules on the Au (111) surface. All the molecules organized to form nano arrays at kink or linear step edge as shown in Fig. 2 (a). This is because the \(\text{C}_{60}\) molecules are mobile on the terrace until they reach the preferred adsorption site (steps or kinks). It is found that these \(\text{C}_{60}\) molecules decorate the FCC stacking region at a low coverage. This shows that the \(\text{C}_{60}\) molecules resides the kinks or steps selectively.

![Magnified STM image of HCP domains and FCC domains of Au (111)](image)

Our analysis reveals that 90% of \(\text{C}_{60}\) nano arrays consist of four or five molecules which are decorating at the step area of Au (111). The intermolecular distance or the nearest neighbor distance (NND) of two \(\text{C}_{60}\) is \(~1\) nm (in crystal).[5] Line profile analysis of \(\text{C}_{60}\) nano arrays (from center to center) were carried for several hundreds of STM topography images in order to reveal the actual length of \(\text{C}_{60}\) molecular nano arrays. Clear reductions of \(\text{C}_{60}\) array lengths were observed. The result clearly state that the spacing of two \(\text{C}_{60}\) molecules in three, four and five molecular arrays is less than \(1\) nm as shown in Table 1. These results uncover the fact that, as the amount of molecules increase in an array, the intermolecular nearest neighbor distance is reduced compared with the reported value of
NND. We believe that some C$_{60}$ in the middle of an array may elongate which results in shortening of the array length.

We further increased the coverage of C$_{60}$ in order to achieve the monolayer deposition of C$_{60}$ for comparing with the result of nano arrays with short lengths. However, we obtained C$_{60}$ islands instead of nano arrays. The nearest neighbor distance between two C$_{60}$ in the newly deposited island is $\sim$1nm. The three lobe structure of C$_{60}$ island can be seen in Figure 2(a) for comparison of line profile analysis. The average results of line profile analysis from our experiment has a $\sim$ 13% reduction of the nearest neighbor distance comparing with the C$_{60}$ monolayer island on the flat terrace.

Figure 2. (a) STM image of periodic arrays of C$_{60}$ selectively residing on the step edge of Au (111), I$_t$ = 20 nA, Vbias= 3.5 V. The inset (I$_t$ = 20 nA, Vbias= 3 V) shows the intermolecular resolution image of one C$_{60}$ nano array (b) Schematic representation C$_{60}$ deposited by self-assembly method on Au(111); (c) Line profile along the green line in (a); and (d) STM topography image of C$_{60}$ island obtained at 77 K using I$_t$ = 20 nA , Vbias= 2 V.

**Table 1.** Summary of lengths, nearest neighbour distance (NND) or intermolecular distance of C$_{60}$ molecular nano arrays.

| Array     | Length$^a$ (nm) | Intermolecular distance$^b$ (nm) |
|-----------|-----------------|----------------------------------|
| Array 1 (Two C$_{60}$) | 0.8620            | 0.8620                            |
| Array 2 (Three C$_{60}$) | 1.7049            | 0.8520                            |
| Array 3 (Four C$_{60}$) | 2.5601            | 0.8503                            |
| Array 4 (Five C$_{60}$) | 3.38136           | 0.8454                            |

$^a$The length from one end to the other end of the nano array.

$^b$The center to center distance between two C$_{60}$ molecules.
Figure 3. (a) Side view of adopted model for C\textsubscript{60} sitting on the four atomic layers of gold. The bottom three layers are fixed and only the top layer is allowed to relax; and (b) top view of C\textsubscript{60} on Au (111).

Figure 4. Computed lowest unoccupied molecular orbital of C\textsubscript{60} on Au (111) with their respective relaxed structures: (a) one C\textsubscript{60}; and (b) two C\textsubscript{60}.

The DFT calculations were carried out using SIESTA [6] in order to provide better understanding of the STM results. The relaxed structure of system shows that some C-C bonds are elongated to certain extents. More theoretical calculations are necessary for the deformation trend in C\textsubscript{60}. Moreover, the charge transfer from substrate to molecule could lead to the Jahn-Teller distortion due to covalent bond formation between the molecule and substrate.[7] To examine the electronic structure of C\textsubscript{60} effectively at reasonable computational cost, we performed series of geometry optimizations with a certain number of gold atoms. The orbital distributions of the lowest unoccupied molecular orbital (LUMO) of C\textsubscript{60} on Au (111) are plotted in Fig 4. These results indicate that the LUMO state of single C\textsubscript{60} is not the same with other case like molecular array consists of two C\textsubscript{60} as computed in Fig 4. The main reason is that the distribution of \pi orbital of two C\textsubscript{60} is higher than the single C\textsubscript{60}. It is obvious that the charge distribution increase with the number of C\textsubscript{60} due to the \pi electron migrating between two C\textsubscript{60} and the substrate, which might lead to the deformation of the orbitals.

4. Conclusion
To conclude, we investigated for the first time the reduction of nearest neighbor distance (NND) of C\textsubscript{60} molecular arrays residing on the step sites of Au (111) which is less than 1 nm combining UHV STM experiments and DFT calculations. We proved that the shortening of nearest neighbor distance of nano molecular arrays is somehow related to the deformation of orbital as revealed by our DFT calculation based detail analysis. Our finding can be used to improve the identical nano scale structures for miniature devices such as photovoltaic devices and single-molecular transistors.
