Abstract

Background

Long noncoding RNAs (lncRNAs) play crucial roles in tumor progression and are dysregulated in glioma. However, the functional roles of lncRNAs in glioma remain largely unknown.

Methods

Using the TCGA and GEPIA2 databases, the overexpression of LINC01578 in glioma tissues was determined and further validated in glioma cell lines. The effects of LINC01578 on proliferation, migration, and invasion in glioma were detected by in vitro and in vivo experiments. RNA immunoprecipitation (RIP), dual luciferase reporter, RNA FISH, and RNA sequencing assays were carried out to elucidate the underlying molecular mechanisms regulated by LINC01578 in glioma. RIP and RT-qPCR was used to analyze the regulatory effect of \( N^6 \)-methyladenosine (m\(^{6}A \)) on aberrantly expressed LINC01578.

Results

Highly expressed LINC01578 was identified in glioma tissues and was associated with poor prognosis in glioma patients. Functional assays showed that LINC01578 regulates glioma growth and metastasis in vitro and in vivo. Mechanistically, LINC01578 sponged miR-6893-3p to upregulate TRIM14 expression, thereby facilitating glioma progression. Furthermore, LINC01578 was upregulated in response to \( N^6 \)-methyladenosine modification, which was attributed to METTL3/YTHDF1-mediated RNA transcripts.

Conclusion

Our results reveal a novel m\(^{6}A /\)LINC01578/miR-6893-3p/TRIM14 pathway for glioma progression and suggest LINC01578 as a novel prognostic indicator and therapeutic target for glioma.

Background

Glioma is the most aggressive and fatal central nervous system tumor due to the high infiltration and invasion rate of glioma cells \[1\]. Glioma are classified by the World Health Organization (WHO) into grades I – IV, based on malignant behavior \[2\]. The highly malignant brain tumor glioblastoma (GBM) has a dismal median patient survival of \(~15\) months, despite the current aggressive standard therapy of surgical resection followed by radiotherapy and temozolomide (TMZ) chemotherapy \[3\]. The mechanism of this type of tumorigenesis is currently unclear, and it often infiltrates into normal brain tissue \[4\].
Therefore, exploration of the mechanism behind the occurrence and development of gliomas and identification of potential biomarkers for timely intervention is crucial.

Recently, the role of non-coding RNAs (ncRNAs) in cancer has attracted increasing attention [5]. Long non-coding RNAs (lncRNAs), defined as ncRNAs more than 200 nucleotides in length, have been reported to be dysregulated in many human cancer types [6]. LncRNAs exert their functions at the translational, transcriptional, and posttranscriptional level and have been found to be involved in cell survival, cell growth, and differentiation [7]. Moreover, it is interesting to note that lncRNAs may play an important role in angiogenesis in glioma [8]. Long noncoding RNA LINC01578 (Chaserr) is a conserved IncRNA located upstream of Chd2 that regulates CHD2 expression [9]. LINC01578 was upregulated in colon cancer and drives colon cancer metastasis through a positive feedback loop via the NF-κB/YY1 axis [10]. However, the roles of LINC01578 in glioma metastasis are still largely unclear.

The $N^\delta$-methyladenosine (m$^6$A) RNA modification, the most abundant internal epi-transcriptomic modification, is found in miRNAs, lncRNAs, and circRNAs [11]. m$^6$A methylation is modified by a protein complex consisting of methyltransferases (writers) such as METTL3, METTL14, and Wilm's tumor protein (WTAP), and is likely to occur in the RRACH motif (R; A or G, H; except for G). This modification is reversible since demethylases such as FTO and ALKBH5 have also been discovered. The m$^6$A modification may require readers, such as the YTH domain-containing 1 (YTHDC1), YTHDC2, YTH $N^\delta$-methyladenosine RNA-binding protein 1 (YTHDF1), YTHDF2, and YTHDF3 [12–14]. These readers regulate RNA processing or metabolism including mRNA alternative splicing, export, translation, and decay [15]. Increasing numbers of studies have shown that m$^6$A modification and its associated regulatory proteins play pivotal roles in the pathogenesis of glioma [16–18]. However, the relationship between the oncogenic role of LINC01578 and m$^6$A modification remains unclear.

In the current study, we determined LINC01578 expression in glioma tissues and revealed its association with the overall survival of glioma patients. We also analyzed the contribution of LINC01578 to the function of glioma in vitro/vivo and the underlying mechanism. We also examined the relationship between dysregulated LINC01578 and m$^6$A modification. Our findings clarify the role of the LINC01578/miR-6893-3p/TRIM14 axis in the tumorigenesis of glioma and suggest LINC01578 as a potential diagnostic and prognostic marker.

**Materials And Methods**

**Patients samples**

Normal human brain and glioma tissues were removed during surgery in the Department of Neurosurgery, the first affiliated Hospital of Wannan Medical College. Tissue samples were snap-frozen in liquid nitrogen and stored at -80°C for RNA extraction. Informed consent was obtained from all participants and/or their legal guardians. This study was approved by the Ethics Committee of the first affiliated Hospital of Wannan Medical College.
Cell lines and cell culture

Four human glioma cell lines (U373, U118, A172, T98G), one normal human glial cell line (HEB), and normal human renal epithelial cells (293T) were purchased from American Type Culture Collection (ATCC, Manassas, VA). All cells were cultured in Dulbecco’s modified eagle medium (DMEM) (Hyclone, GE Healthcare Life Sciences, Logan, UT, USA) and grown in an incubator at 37°C and 5% CO₂ in DMEM mixed with 10% (v/v) fetal bovine serum (FBS) (Gibco, Life Technologies, Grand Island, NY).

RNA extraction and RT-qPCR

Total RNA from frozen brain tissues and cultured cells were extracted using Trizol reagent (Ambion, life technologies, Carlsbad, CA, USA) as previously described [19]. cDNA from total RNA was synthesized using RevertAid First Strand cDNA Synthesis Kit (Thermo Scientific, Vilnius, Lithuania, USA). The gene expression were measured by real-time quantitative PCR utilizing QuantiNova™ SYBR® Green PCR Kit (Qiagen, Hilden, Germany) on the CXF96 PCR system (Bio-Rad, Hercules, CA, USA). The primer sequences were as follows in Table S1. GAPDH and U6 were served as internal control.

Cell transfection

The short hairpin RNAs (shRNA) lentivirus (sh-NC, sh-LINC01578) was purchased from HANBIO (Shanghai, China). Lentiviruses were transfected into glioma cells for 48 h, and stable cell clones were selected after one week using puromycin (5 µg/ml). Small interfering RNA (siRNA), microRNA mimics (agomir), and microRNA inhibitor (antagomir) were purchased from RiboBio (Guangzhou, China) and transfected using the riboFECT™ CP Transfection Kit (RiboBio) via the manufacturer’s protocol. For overexpression, the LINC01578 cDNA was cloned into the pTSB02-GFP-PURO vector and transfected using Lipofectamine 3000 (Invitrogen, Carlsbad, CA) following the manufacturer’s instructions. For YTHDF1 RNA interference, the cells were transfected with 30 nM siRNA (GenePharma, China) targeting the YTHDF1 and a control siRNA using Lipofectamine RNAiMAX (ThermoFisher, 3778150, USA) following the manufacturer’s instructions. The sequences used are provided in Table S2.

Cell proliferation and colony formation

Cell proliferation was determined using a Cell-Light EdU Apollo567 In Vitro Kit (RiboBio; Guangzhou; China), following the manufacturer’s instructions. Finally, the cells were captured using a fluorescence microscopy. For the colony formation assay, glioma cells were seeded in 6-well plate at 5000 cells/well. Approximately 2 weeks later, the cells were fixed in paraformaldehyde and stained with crystal violet. The colonies were imaged and counted.

Invasion and migration assays

Transwell chambers were used for the migration assays. Cells (2 × 10⁴) cells were suspended in 100 µl serum-free medium and seeded in the upper chamber. For invasion assays, the upper chambers were precoated with diluted Matrigel (356234; BD Biosciences) and 4 × 10⁴ cells were added to the upper
chamber. The lower chamber contained 600 μl DMEM medium with 10% serum. After 24 h, the migrated or invasive cells were fixed, stained, and counted.

Wound-healing assay was also used for the migration assay. The glioma cells were seeded on 6-well cell culture plates and scratched using 200 μl pipettes. The cells were cultured in DMEM medium without FBS and a microscope was used to capture photographs at 24 h.

**Fluorescence in situ hybridization (FISH)**

Specific FISH probes for LINC01578 were designed and synthesized by RiboBio (Guangzhou, China) and miR-6893-3p was designed and synthesized by Boster (Wuhan, China). Glioma cells grown on glass coverslips were fixed in 4% paraformaldehyde (PFA) for 30 minutes and permeabilized with 0.5% Triton X-100. Then, cells were washed three times with phosphate buffer saline (PBS) and treated with pre-hybridization buffer (2 × saline sodium citrate, 10% formamide). The FISH probes for LINC01578 were resuspended in the hybridization buffer (2 × saline sodium citrate, 10% formamide, 10% dextran sulphate) to a final concentration of 250 nmol/L per probe set. Hybridization was carried out in a humidified chamber at 37°C for 16 hours, and then cells were washed three times with PBS. Then, the FISH probes for miR-6893-3p were resuspended in the hybridization buffer, and hybridization was carried out in a humidified chamber at 37°C for 16 hours. After incubation, cells were washed three times with 4 × saline sodium citrate (SSC) plus with 0.1% Tween-20 at 42°C, followed by one wash with 2 × SSC and one wash with 1 × SSC at 42°C. Cells were then washed three times with PBS and nuclei were labelled with DAPI. We continued with several rounds of washing and finished with mounting the coverslip onto a microscope slide using an anti-fade mounting medium. For the fluorescence in situ hybridization of glioma tissues, the tissues were fixed with neutral formalin and the paraffin-embedded tissue sections were placed on clean glass slides. The slides were placed on a baking sheet machine at 65°C overnight. Tissue sections were then soaked in a dye vat filled with xylene for 10 minutes and then immediately immersed in 100% ethanol, 85% ethanol, and 70% ethanol for 2 minutes followed by immersion in deionized water for 3 minutes. After the sections were removed, they were dried with a lint-free paper towel to remove excess water, immersed in 2 × SSC solution, and rinsed for 5 minutes. Sections were then treated with proteinase K working solution at 37°C for 30 minutes, immersed in 2 × SSC solution for 5 minutes, and rinsed sequentially in 70% ethanol, 85% ethanol, and 100% ethanol for 2 minutes and then dried naturally. After mixing the LINC01578/miR-6893-3p, 10 μl drops were deposited on the hybridization area of the tissue section and covered with a cover glass. Sections were then placed on the hybridization instrument, denatured at 83°C for 5 min, and hybridized at 42°C for 16 h. Then, the cover glass was removed and the hybridized sections were placed in 0.4 × SSC solution and 2 × SSC solution for 2 minutes in turn, soaked in 70% ethanol for 3 minutes, and dried naturally. Finally, 10 μl of DAPI counterstaining solution was dropped on the hybridization area, covered with a cover glass, and hybridized for 20 minutes. All images were analyzed on a confocal laser scanning microscope (Zeiss LSM800 confocal microscope, Mainz, Germany). The FISH probe sequence was as follows: miR-6893-3p: 5’-CTGGCAGGTAAGGCAGCGG -3’.
RNA immunoprecipitation (RIP)

RIP assay was performed using a Magna RIP RNA-binding Protein Immunoprecipitation Kit (Millipore, MA, USA) in accordance with the manufacturer's protocol. Glioma cells were isolated and lysed by RIP lysis buffer and incubated with antibodies against AGO2 (Abcam, Cambridge, UK), or m6A (Abcam, Cambridge, UK) at 4 °C overnight. IgG was used as negative control. The immunoprecipitated RNAs were eluted and analyzed by RT-qPCR.

Western blotting (WB)

TRIM14 was purchased from Proteintech (Chicago, USA). PTEN, p-Akt, Akt, p-mTOR, mTOR, p-P70S6K, P70S6K, Cyclin D1, Cyclin E1, PCNA were purchased from Cell Signaling Technology (Beverly, MA, USA). E-cadherin, N-cadherin, MMP-9 and MMP-2 antibodies were obtained from Santa Cruz Biotechnology (Dallas, TX, USA). HRP-conjugated and anti-rabbit IgG secondary antibodies were obtained from Cell Signaling Technology (Beverly, MA, USA). Cells or tissues were harvested at the indicated times and lysed in radio immunoprecipitation assay (RIPA) extraction solution. The protein concentration was determined by a BCA Protein Assay kit (Beyotime, China). Total protein lysates (25 mg/lane) were subjected to SDS-PAGE and transferred onto an Immobilon polyvinylidene difluoride (PVDF) membrane (Millipore, MA, USA). The membranes were blocked for 1 h with 5% non-fat dry milk at room temperature and were incubated with diluted primary antibodies at 4°C overnight, followed by treatment with HRP-conjugated secondary antibodies for 1 h at room temperature. Antibody-antigen complexes were visualised using either a LI-COR Odyssey Infrared Imaging System (LI-COR Biosciences) or a chemiluminescence imaging system (Clinx, Shanghai, China). Protein levels were semi-quantified using Image J 1.52 software.

Luciferase activity experiment

The 293T and A172 cells (1 × 10^5 cells/well) were seeded into 24-well plates. Cell were co-transfected with the constructed luciferase plasmids and miR-6893-3p mimics or negative control using Lipofectamine 3000 reagent (Invitrogen, USA) for 48 h. Then, firefly and renilla luciferase activities were measured using the Dual-Luciferase Reporter Assay System (Promega, Madison, WI, USA) following the manufacturer's protocol.

In vivo tumor xenotransplantation

Xenograft athymic mice models were constructed to examine the effects of LINC01578 on glioma tumor growth in vivo. BALB/c athymic mice are fed in an SPF environment (temperature: 23-24°C, humidity: 30-50%), and free food and water are provided throughout the process. Glioma cells with shLINC01578 or shNC and corresponding control cells were injected subcutaneously into the flanks of 4-week-old BALB/c athymic mice (weighting approximately 20 g each; 5 × 10^6 cells resuspended in 200 mL of culture medium). Tumors were measured routinely with a caliper. The xenograft volume was calculated as (longest diameter × smallest diameter^2)/ 2.
BALB/c athymic mice were sacrificed 30 days later and tumors were collected. During the experiment, observe at least three times a week. The clinical symptoms of the experimental animals were evaluated and consulted with professional veterinarians and the health and welfare of the animals were put first. For animals in pain, analgesics were used to relieve them in time. All animals were euthanized by intravenous injection of 100 mg/kg sodium pentobarbital. The xenografts were harvested and weighed. All animal experiments were approved by the Animal Ethics Committee of the First Affiliated Hospital of Wannan Medical College.

**Bioinformatics analysis**

Differentially expressed genes data analyses and survival analysis. We used including the Cancer Genome Atlas database (TCGA. http://tcga-data.nci.nih.gov/tcga/), the Gene Expression Profiling Interactive Analysis 2 databases GEPIA2. http://gepia2.cancer-pku.cn/ to analyse the gene expression data and overall survival. Differentially expressed genes data analyses, we used the Omcomine databases (http://www.oncomine.org/) and the TIMER databases (http://www.timer.cistrome.org/), were performed using R software.

**Histological analysis and immunohistochemistry (IHC)**

For hematoxylin and eosin (H&E) staining (G1005, Servicebio), glioma tissues were fixed with 10% neutral formalin for 24 h, dehydrated, embedded in paraffin, and then cut into 5-µm-thick sections. After being dewaxed and treated with gradient alcohol, the sections were stained with hematoxylin for 5 min at room temperature and washed with running water. Subsequently, an alcohol solution with 1% hydrochloric acid and ammonia was employed. Eosin (1%) was utilized for further staining for 3 min at room temperature, gradient ethanol was used for section dehydration and neutral balsam for section mounting, followed by microscopic visualization (Nikon, Japan).

IHC Sections of formalin-fixed paraformaldehyde-embedded cancerous glioma tissues were dewaxed and rehydrated. The endogenous peroxides were quenched by 0.3% hydrogen peroxide. These sections were initially incubated with primary antibodies and then with horseradish peroxidase (HRP)-conjugated secondary antibodies. Finally, the signal in various sections was analyzed using diaminobenzidine. After the sections were sealed with neutral glue, images were obtained using a microscope (Nikon, Japan).

**RNA sequencing analysis**

T98G cells were transfected with sh-NC (n = 3) or sh-LINC01578#2 (n = 3) for 48 h. Then, total RNA was extracted using TRIzol reagent (Ambion, life technologies, Carlsbad, CA, USA) according to the manufacturer's instructions. Perform transcriptome sequencing, extract the total RNA of the sample and digest the DNA with DNase, use magnetic beads with Oligo (dT) to enrich the eukaryotic mRNA, add the interrupting reagent to interrupt the mRNA into short fragments to interrupt the mRNA is used as a template for PCR amplification, after the constructed library is qualified with Agilent 2100 Bioanalyzer(Agilent Technologies, Inc.), it is sequenced using sequencers such as Illumina HiSeqTM 2500
or Illumina HiSeq X Ten(SF, USA). Significantly differentially expressed genes (DEGs) between sh-NC and sh-LINC01578#2 cells were identified based on fold change ≥ 1.5 and P-value ≤ 0.05 using the DEGseq functions. The transcriptome sequencing and analysis were conducted by OE biotech Co., Ltd. (Shanghai, China).

**Statistical analysis**

Data are presented as the mean ± SD of three independent experiments. All statistical were calculated in GraphPad Prism 6 by Student's t test to compare the data. One-way analysis of variance followed was used to compare the difference among different groups. Differences were considered statistically significant at *p < 0.05, **p < 0.01 and ***p < 0.001.

**Results**

**LINC01578 was significantly upregulated in the gliomas**

To examine the function of IncRNA in glioma tumorigenesis, we obtained the genome wide expression from TCGA databases (http://tcga-data.nci.nih.gov/tcga/). We found LINC01578 exhibited significant upregulation in the glioma tissues compared to the normal tissues (Fig. 1A and Additional file: Table S1). In GEPIA2 database (http://gepia2.cancer-pku.cn/), the LINC01578 was highly expressed in GBM (glioblastoma multiforme) and LGG (low grade glioma) (Additional file 1: Fig. S1A). And high LINC01578 expression correlated with poorer overall survival in glioma patients(Additional file 1: Fig. S1B). To confirm the databases results, we performed RT-qPCR to quantify the expression levels of LINC01578 in brain tissues and cell lines. Compared with normal tissues, LINC01578 expression was upregulated in glioma tissues. LINC01578 was overexpression in glioma cell lines (Fig. 1B-C). Fluorescence in situ hybridization (FISH) indicated that LINC01578 mainly located in the cytoplasm (Fig. 1D).

**LINC01578 knockdown decreases proliferation and metastasis**

The RT-qPCR shown that the shLINC01578#2 exhibited the higher knockdown effect in T98G and A172 cells (Additional files: Fig S2). EdU and colony formation assays indicated that LINC01578 knockdown significantly inhibited the proliferation of glioma cells (Fig. 2A-B). Wound-healing assay demonstrated migration of glioma cells was significantly suppressed when LINC01578 was downregulated. Transwell analysis confirmed that LINC01578 knockdown inhibited the migratory and invasive potential of glioma cells (Fig. 2C-E). These results suggesting that LINC01578 may regulate proliferation and metastasis. Western blot analysis was used to detect the proliferation and metastasis related protein. Proliferating cell nuclear antigen (PCNA) plays an essential role in the proliferation process [20]. Cyclin D1 and E1 are important regulator of cell cycle [21-22]. In LINC01578-silenced cells, expression of PCNA, Cyclin D1 and E1 were decreased. Then we determined the expression of MMP2, MMP9, E-cadherin and N-cadherin which is required for tumor metastasis [23-26]. We found that MMP2, MMP9, N-cadherin was significantly
downregulated, whereas the E-cadherin were upregulated with reduced LINC01578 (Fig. 2F). Collectively, our data suggested that LINC01578 function on proliferation/migration and invasion of glioma cells.

**LINC01578 targets miR-6893-3p in glioma**

As LINC01578 is mainly located in the cytoplasm, LINC01578 might exert its effects via targeting miRNAs. RIP assays showed that LINC01578 binds to Ago2 (Fig.3A), the core component of microRNA (miRNA)-induced silencing complex [27]. These results indicated that LINC01578 may functions as a ceRNA and sponges miRNAs. To confirm this hypothesis, 4 bioinformatics databases (miRanda, TargetScan, RNAhybrid and starBase) were used to predict the potential interaction between LINC01578 and miRNAs. Through the database, we identified 5 miRNA contains binding sites (Fig. 3B and Additional file: Table S2). These results indicated that LINC01578 may act as the miR-6893-3p sponge.

To confirm the potential binding, a luciferase reporter assay was performed. In the 293T tool cell LINC01578-wt group, miR-6893-3p mimics significantly reduced the luciferase activity, and miR-6893-3p inhibitor significantly increased the luciferase activity. However, the luciferase activity was unchanged in LINC01578-mut group which putative miR-6893-3p binding site in the LINC01578 sequence was mutated, the same trend of luciferase reporter gene determination in A172 cell line (Fig. 3C). The FISH assays shown LINC01578 was colocalized with miR-6893-3p in the cytoplasm (Fig. 3D). These results suggest that LINC01578 functions as a miR-6893-3p sponge in glioma cells. In order to detected the expression level of miR-6893-3p, we performed RT-qPCR to quantify the expression levels of miR-6893-3p in brain tissues and cell lines. Compared with normal tissues, miR-6893-3p expression was downregulated in glioma tissues. miR-6893-3p was low expressed in glioma cell lines (Fig. 3E-F). We investigated the expression levels of miR-6893-3p in glioma cells transfected with miR-6893-3p mimics or inhibitor, the transfection efficiency of glioma cell lines was successful (Additional files: Figure S3).

**LINC01578 targets miR-6893-3p to exert its function in glioma**

To investigate the interactions among LINC01578 and miR-6893-3p on the progression of glioma, rescue experiments were performed. We knockdown the expression of miR-6893-3p in LINC01578-silenced glioma cells and detected the proliferation/migration and invasion in glioma cells. The EdU and colony formation assays indicated that miR-6893-3p inhibitor suppressed the decreased cell proliferation ability in LINC01578 knockdown glioma cells (Figure 4A and B). Furthermore, reduction effect of LINC01578 on cell migration and invasion was partially eliminated by miR-6893-3p knockdown (Fig. 4C). Similarly, the effects of down-regulation of PCNA, Cyclin D1 and E1, MMP2, MMP9, N-cadherin proteins and upregulation of E-cadherin protein in LINC01578 knockdown cells were reversed by miR-6893-3p inhibitor (Fig. 4D). These results suggest that LINC01578 affects glioma cells proliferation and metastasis by sponging miR-6893-3p.

**TRIM14 is a direct target of miR-6893-3p in glioma**
To determine the targets of miR-6893-3p regulated by LINC01578, RNA sequencing was used to analyze the differentially expressed genes in LINC01578 knockdown cells. 904 genes were downregulated and 144 genes were upregulated in shLINC01578 group compared to NC group (Fig. 5A and Additional file: Table S3). Then take the intersection of the 5 miRNA target genes (miRanda, TargetScan, RNAhybrid bioinformatics databases were used to predict the target genes) and the list of differentially expressed genes in the LINC01578 knockdown cells analyzed by RNA sequencing in Figure 5A (Fig. 5B and Additional file: Table S4). We constructed a ceRNA network with the downregulated genes and target genes of miR-6893-3p (Fig. 5C and Additional file: Table S5). We selected TRIM14 that have obvious differences and may have potential functions in the progression of glioma for research. Many studies have shown that TRIM family proteins play important roles in various physiological processes, including cell proliferation, migration, invasion, apoptosis and differentiation, and cell cycle. Therefore, TRIM14 was selected as a putative target of miR-6893-3p regulated by LINC01578 for further research.

The dual-luciferase reporter assay was used to validated their relationship. In the 293T tool cell TRIM14-wt group, miR-6893-3p mimics significantly reduced the luciferase activity, and miR-6893-3p inhibitor significantly increased the luciferase activity. However, the luciferase activity was unchanged in TRIM14-mut group which putative miR-6893-3p binding site in the TRIM14 sequence was mutated. The same trend of luciferase reporter gene determination in A172 cell line (Fig. 5D). We investigated the expression levels of LINC01578 in glioma cells transfected with overexpression LINC01578, The transfection efficiency of glioma cell lines was successful (Additional files: Fig S4a). In glioma cells, RT-qPCR and western blot results showed TRIM14 expression was decreased when LINC01578 was inhibited. TRIM14 expression was increased when LINC01578 was overexpressed (Additional files: Figure S4B-C). RT-qPCR and western blot results showed TRIM14 expression was decreased when miR-6893-3p was overexpressed. TRIM14 expression was increased when miR-6893-3p was inhibited (Additional files: Figure S4D-E). The GEPIA2 database shown TRIM14 was highly expressed in glioma tissues (Fig. 5E). The TCGA database shown that the higher the WHO grade of glioma patients, the higher the expression of TRIM14 (Fig. 5F and Additional file: Table S6). In addition, receiver operating characteristic (ROC) curve analysis was determined to evaluate the diagnostic value of LINC RNA 01578 for glioma (Fig. 5G and Additional file: Table S7).

TRIM14 mRNA expression levels were analyzed in Oncomine to examine TRIM14 expression over a cancer-wide range (Additional files: Fig. S5A), the results revealed that compared with that in the normal groups, TRIM14 expression was higher in brain and CNS cancer groups. To further evaluate TRIM14 expression in pan-cancer, we examined RNA sequencing data in TCGA using TIMER. The differential TRIM14 expression patterns in tumor and adjacent normal tissues are shown in Additional files: Fig. S5B and Additional file: Table S8. Potential interactions between TRIM14 and other genes were analyzed using GeneMANIA (http://genemania.org). (Additional files: Fig. S5C and Additional file: Table S9). The GEPIA2 database shown higher TRIM14 expression levels were significantly correlated with shorter overall survival (Additional files: Fig. S5D). Subsequently, Kaplan-Meier survival curves all WHO grade glioma patients and overall survival in all patients with glioma from the TCGA database showed that the overall survival of glioma patients with high levels of TRIM14 were shorter than patients with low levels
of LINC01578 expression (Additional file 1: Fig. S5E and Additional file: Table S10). Our RT-qPCR results showed TRIM14 was remarkably increased in glioma tissues and cells (Fig. 5H-I). Our western blot results showed TRIM14 was remarkably increased in glioma cells (Fig. 5J).

**TRIM14 contributes to the function of miR-6893-3p**

The RT-qPCR and western blot shown that the si-TRIM14#1 exhibited the higher knockdown effect in T98G and A172 cells (Additional files: Figure S6A-B). To further investigate miR-6893-3p that affects glioma cell by regulating TRIM14, we proved that TRIM14 knockdown inhibited the proliferation, colony formation, migration. (Fig. 6A-C). Then, we explored whether miR-6893-3p downregulation counteracted the suppression of cell phenotypes caused by TRIM14 knockdown in glioma cells. In the T98G and A172 cells, inhibition of cell phenotypes by TRIM14 knockdown was counteracted by downregulation of miR-6893-3p. Taken together, these results that miR-6893-3p affects glioma cell proliferation, migration, and invasion by regulating TRIM14 expression.

**LINC01578 promotes the Akt/mTOR/P70S6K pathway**

To determine the potential mechanism of how LINC01578 regulated the migration and invasion of glioma cells, we performed western blot analysis to investigate the effects of lncRNA LINC01578 knockdown on the Akt/mTOR signaling pathway, which is often plays an important role in the progression of human cancer tumor cells. To investigate whether LINC01578 regulate the Akt/mTOR/P70S6K pathway by miR-6893-3p/TRIM14 axis, we determined the expression of phosphorylated Akt/mTOR/P70S6K. LINC01578 overexpression promoted the expression of the phosphorylated forms of Akt, mTOR, P70S6K, but inhibited PTEN expression. While the phosphorylation of Akt, mTOR, P70S6K was suppressed in miR-6893-3p-overexpressed cells (Fig. 7A-B). Further study shown sh-LINC01578-mediated inactivation of the Akt/mTOR/P70S6K signaling pathway was reversed upon co-transfection with miR-6893-3p inhibitor (Fig. 7C). The phosphorylation of Akt, mTOR, P70S6K was suppressed in TRIM14-silenced cells (Fig. 7D).

**LINC01578 facilitates glioma growth in vivo**

A xenograft mouse model was used to examine the function of LINC01578 on glioma growth in vivo. Compared with NC group, the tumor weight and volume in LINC01578 knockdown group was significantly inhibited (Fig. 8A-C). We then detected the TRIM14 expression in the tumors of xenograft mouse model by RT-qPCR and western blot. The expression level of TRIM14 in LINC01578 knockdown group was decreased (Fig. 8D-E).

**m^6^A modification is involved in the upregulation of LINC01578 in glioma**

The epigenetic mechanisms of m^6^A modification responsible for the upregulation of LINC01578 in glioma cells were investigated. m^6^A RIP qPCR showed m^6^A modification of LINC01578 was highly existed in T98G and A172 cells (Fig. 9A). METTL3 is defined as the main methyltransferase of the m^6^A modification and involved in glioma development [28-29]. The RT-qPCR and western blot shown that the
si-METTL3#1 exhibited the higher knockdown effect in T98G and A172 cells (Additional files: Fig. S6). We found that METTL3 knockdown inhibited LINC01578 expression in glioma cells. Meanwhile, m^6^A modification of LINC01578 was decreased in METTL3-silenced glioma cells (Fig.9A-B). To further clarify mettl3-mediated m^6^A modification on LINC01578 expression, we predicted a RRACU m^6^A sequence motifs of LINC01578 from 3 bioinformatics database (RFAtM6A, SRAMP, BERMP) (Fig. 9C and Additional file: Table S11.). Next, we constructed a mutant form of LINC01578, in which the adenine residues in the m^6^A motifs were replaced with guanine (A-G transition mutation) (Fig. 9D). Luciferase reporter assay revealed that transcriptional level of wild-type LINC01578, but not the mutation, significantly decreased in the METTL3 knockdown group (Fig. 9E). By treating glioma cells with actinomycin-D to inhibit transcription, the half-life of LINC01578 was decreased in METTL3-silenced cells (Fig. 9F). These data suggested that METTL3-mediated m^6^A is associated with the upregulation of LINC01578, probably by regulating the stability of its transcript. According to the RMBase v2.0 database [30], YTHDF1 is an RNA-binding protein (RBP) of LINC01578. YTHDF protein can directly bind to and recognize m^6^A-modified IncRNAs. RIP qPCR assay showed that YTHDF1 directly bonded to LINC01578 to form an m^6^A modification complex (Fig. 9G). RT-qPCR showed that the inhibitory efficiency of YTHDF1 in glioma cell lines proved that the inhibition was successful (Fig. 9H). Moreover, RT-qPCR indicated that expression of LINC01578 was decreased in YTHDF1-silenced cells (Fig. 9I). In conclusion, these results indicating that METTL3 mediate m^6^A modification of LINC01578, YTHDF1 selectively binds to m^6^A-modified LINC01578 and modulates LINC01578 expression.

Discussion

Accumulating evidence has demonstrated that many dysregulated IncRNAs in glioma are closely related to tumorigenesis, metastasis, and prognosis or therapies[31]. In this study, a TCGA and Gepia databases was used to screen the differentially expressed IncRNAs in glioma and LINC01578 was upregulated in glioma. Highly expressed LINC01578 also associated with a poor prognosis of glioma patients. However, the function and molecular mechanism of LINC01578 in glioma remain need further study. Functional experiments in vivo and in vitro demonstrated that LINC01578 regulated glioma tumorgenesis, such as proliferation, migration, invasion, and tumor growth.

Since the functional mechanism of IncRNAs depends on their subcellular localization, IncRNAs can also be grouped into nuclear or cytoplasmic categories [32]. Most of LINC01578 is in cytoplasm, suggesting that LINC01578 may serve as a miRNA sponge. We defined the miR-6893-3p as the targets of LINC01578 by using bioinformatics databases, RIP, dual luciferase reporter, and FISH assays. Further functional experiments showed that LINC01578 sponged miR-6893-3p to promote glioma progression. The miR-6893-3p which has less research was found upregulated in the serum multiple myeloma (MM) [33].

A comprehensive analysis combined RNA sequencing results and bioinformatics databases was used to investigate the target gene of the miR-6893-3p regulated by LINC01578 in glioma. The ceRNA network indicate that TRIM14 was the downstream effector of the LINC01578/miR-6893-3p axis. TRIM family
proteins play important roles in various physiological processes, including cell proliferation, migration, invasion, apoptosis and differentiation, and the cell cycle [34]. TRIM14 was upregulated in human glioblastoma and functions as a novel regulator of EMT by controlling the abundance of ZEB2 [35]. TRIM14 also play a specific biological role of in temozolomide resistance of glioma cells [36–37]. Functional experiments showed that TRIM14 contributes to the function of miR-6893-3p in glioma.

Gathering evidence has revealed that Akt signaling pathway plays an important role in glioma progression and aggressiveness [38]. Therefore, targeting Akt could provide an important approach for glioma prevention and therapy [39]. KEGG enrichment show that Akt signaling pathway was downregulated following LINC01578 knockdown in glioma. Our results revealed that LINC01578 acts as a tumour promote via the miR-6893-3p to active the Akt signaling pathway in glioma. TRIM14 regulates cell proliferation and invasion in osteosarcoma and melanoma via promotion of the PTEN/PI3K/Akt signaling pathway [40–41]. The Akt/mTOR/P70S6K pathway also affected by TRIM14 in glioma. Therefore, we hypothesized LINC01578/miR-6893-3p/TRIM14 axis promoted glioma cells proliferation, migration, and invasion via activating Akt/mTOR/P70S6K pathway.

m^6^A has been demonstrated to affect the targeted lncRNA and participate in the progression of glioma. METTL3 enhances the stability of MALAT1 with the assistance of HuR via m6A modification in IDH-wildtype glioma [29]. m^6^A-related IncRNAs are potential biomarkers for predicting the overall survival of glioma patients [42]. We revealed that m^6^A methylation was enriched within LINC01578 in glioma cells using m^6^A RIP experiment. Moreover, METTL3 regulated the m^6^A modification in LINC01578, thus affecting its RNA stability. YTHDF3 facilitates translation of protein synthesis in synergy with YTHDF1 and affects decay of methylated mRNA mediated through YTHDF2 [43]. YTHDF3 selectively binds m^6^A-methylated GAS5 to trigger its decay [13]. In our study, YTHDF1 selectively binds to m^6^A-modifed LINC01578 and modulates LINC01578 expression.

**Conclusion**

In summary, we have shown that LINC01578 is upregulated in glioma and High LINC01578 level was associated with the poor prognosis in glioma patients. LINC01578 play role on cell proliferation, migration, and invasion by modulating the miR-6893-3p/TRIM14 axis. LINC01578/miR-6893-3p/TRIM14 axis also regulates the Akt/mTOR/P70S6K pathway. Additionally, we provide evidence that METTL3 and YTHDF1 mediated m^6^A modification was responsible for the upregulation of LINC01578 in glioma. Our study of LINC01578 may provide a prognostic predictor and therapy target for the treatment of glioma.
