Hyperbaric oxygen therapy for the treatment of long COVID: early evaluation of a highly promising intervention

Authors: Tim Robbins, Michael Goeveski, Cain Clark, Sudhanshu Baitule, Kavi Sharma, Angel Magar, Kiran Patel, Sailesh Sankar, Ioannis Kyrou, Asad Ali and Harpal S Randeva

Background
Long COVID is a common occurrence following COVID-19 infection. The most common symptom reported is fatigue. Limited interventional treatment options exist. We report the first evaluation of hyperbaric oxygen therapy (HBOT) for long COVID treatment.

Methods
A total of 10 consecutive patients received 10 sessions of HBOT to 2.4 atmospheres over 12 days. Each treatment session lasted 105 minutes, consisting of three 30-minute exposures to 100% oxygen, interspersed with 5-minute air breaks. Validated fatigue and cognitive scoring assessments were performed at day 1 and 10. Statistical analysis was with Wilcoxon signed-rank testing reported alongside effect sizes.

Results
HBOT yielded a statistically significant improvement in the Chalder fatigue scale (p=0.0059; d=1.75 (very large)), global cognition (p=0.0137; d=-1.07 (large)), executive function (p=0.0039; d=-1.06 (large)), attention (p=0.0020; d=-1.2 (very large)), information processing (p=0.0059; d=-1.25 (very large)) and verbal function (p=0.0098; d=-0.92 (large)).

Conclusion
Long COVID-related fatigue can be debilitating, and may affect young people who were previously in economic employment. The results presented here suggest potential benefits of HBOT, with statistically significant results following 10 sessions.

Introduction
The COVID-19 pandemic has resulted in the need to support large cohorts of patients suffering from long COVID after recovery from acute infection. Long COVID is a term ‘used to describe presence of various symptoms, even weeks or months after acquiring SARS-CoV-2 infection irrespective of the viral status’. Long COVID is a common condition, with estimates identifying that between 10% and 20% of people initially diagnosed with acute COVID-19 will go on to develop symptoms of long COVID. There remains some debate about the terminology used in long COVID, with the UK National Institute for Health and Care Excellence (NICE) also using the terminology ‘post-COVID-19 syndrome’ for signs and symptoms that develop during or after an infection consistent with COVID-19, continue for more than 12 weeks and are not explained by an alternative diagnosis, and ‘ongoing symptomatic COVID-19’ for signs and symptoms of COVID-19 from 4 to 12 weeks. However, NICE also recognises the umbrella term ‘long COVID’.

Long COVID now poses an emerging public health emergency with multiple challenges for the management of these patients in clinical practice. The symptoms associated with long COVID are diverse, including breathlessness, cough, fatigue, ‘brain fog’, anxiety and depression. One of the most commonly reported symptoms is fatigue, present in up to 65% of long COVID patients, this is accompanied by a substantial proportion also reporting cognitive and affective deficits (described in the literature as ‘brain fog’). The fatigue experienced by these patients can be particularly severe, preventing them from performing their usual
work and activities, while the age group most affected by long COVID tends to be economically active adults.12

Currently specific treatment options for long COVID are limited, with even fewer treatment options available for those suffering from fatigue.13,14 Thus, there is a growing need to identify effective treatments for these patients.15 Despite distinct differences, there are important similarities between long COVID fatigue and chronic fatigue syndrome.8,16

Hyperbaric oxygen therapy (HBOT) is ‘an intervention where an individual breathes near 100% oxygen intermittently while inside a hyperbaric chamber that is pressurized to greater than sea level pressure (1 atmosphere absolute, or ATA).17,18 HBOT is used for both elective (eg soft tissue radiation complications and non-healing chronic wounds) and emergency medical conditions (eg carbon monoxide poisoning, decompression illness and gas embolism).19 In particular, HBOT has been shown to be safe and effective in the treatment of chronic fatigue syndrome.19,20 At University Hospitals Coventry and Warwickshire NHS Trust, working in direct partnership with the Midlands Diving Chamber at the Rugby Hospital of St Cross, we proposed that HBOT may be of benefit to people suffering from symptoms of long COVID. The first patient to receive HBOT for long COVID received this on the 11 January 2021. Currently, there is no study to our knowledge which explored the effects of HBOT on long COVID-related fatigue. Here we present the first evaluation of a HBOT service for the treatment of long COVID symptoms internationally.

Methods

We retrospectively evaluated the response of fatigue symptoms of patients with long COVID-related fatigue receiving HBOT at the Midlands Diving Chamber medical facility, Hospital of St Cross, Rugby. This retrospective evaluation was approved by the University Hospitals Coventry and Warwickshire NHS Trust COVID-19 Research Ethics Committee through the GAFREC Process (ID: 10026).

We evaluated 10 consecutive patients undergoing HBOT for long COVID-related fatigue at the Midlands Diving Chamber. All patients were suffering from new fatigue that developed during or after an infection consistent with COVID-19 and continuing for more than 12 weeks. The clinical inclusion and exclusion criteria for these patients are listed in Table 1.

All patients received 10 HBOT sessions, once daily at 2.4 atmospheres for 1 hour and 45 minutes over 12 days (with a 2-day break in the middle for the weekend).

The responses of these 10 consecutive patients receiving HBOT therapy were evaluated with the primary outcome measure being the change in Chalder fatigue scale between days 1 and 10 of treatment.21 The secondary measure evaluated was the change in the cognitive profile scores of day 1 and day 10, as reported through the NeuroTrax evaluation.22 This scoring included global cognitive score, memory, executive function, attention, information processing speed, visual-spatial, verbal function and motor skills.

Statistical analysis

In order to investigate differences between day 1 and day 10 undergoing HBOT, Wilcoxon signed-rank testing was conducted, and reported alongside corresponding effect sizes (Cohen’s d; classified as small (0.2), medium (0.5), large (0.8) or very large (1.2), and 95% confidence intervals (CIs)).23 In addition, Bayes factors were also calculated to express the probability of a difference given H10 (alternate hypothesis) relative to H0 (null hypothesis), that is, values larger than 1 are in favour of H10 assuming that H0 and H10 are equally likely and using a default prior.24 Bayes factors were reported as the probability of the data given the alternative relative to the null hypothesis or vice-versa (classified as anecdotal (BF > 3), moderate (BF = 3–10), strong (BF = 10–30), very strong (BF = 30–100) or extreme (BF > 100)).25–27 Bayesian analysis was concurrently utilised because it permits the amalgamation of discipline-specific knowledge, facilitates direct probability statements to be made pertaining to included parameters (ie population level effects), allows zero effects to be determined, provides estimates of uncertainty around parameter values that are more intuitively interpretable than those from null hypothesis testing alone, and supports in the interpretation of p values.28,29 All analyses were conducted using R software.30

Results

In the present cohort, 60% of the patients were women. The mean average age of participants was 47.5 years (range 24–74). All patients had been suffering from long COVID symptoms for over 3 months.

Participant level and overall group data for all collected validated scores between day 1 and day 10 of HBOT are presented in Table 2. Wilcoxon signed-rank tests indicated that once daily HBOT for 10 days yielded a statistically significant improvement in Chalder fatigue scale (p=0.0059; d=1.75 (very large)), global cognition (p=0.0117; d=−1.07 (large)), executive function (p=0.0039;
Table 2. Day 1 vs day 10 of hyperbaric oxygen therapy

|                      | p value    | Mean difference (95% CI)    | Cohen's d   | BF    |
|----------------------|------------|-----------------------------|-------------|-------|
| Global cognition     | 0.0137a    | −8.4 (−14.55 to −2.9)       | −1.07       | 7.626 |
| Memory               | 0.8457     | 0.9 (−10.6 to −7)           | −0.01       | 0.3091|
| Executive function   | 0.0039a    | −7.3 (−12.65 to −2.2)       | −1.06       | 7.3286|
| Attention            | 0.0020a    | −7 (−12.45 to −2.05)        | −1.2        | 12.5093|
| IPS                  | 0.0059a    | −15.3 (−29.8 to −8.2)       | −1.25       | 15.3199|
| Visual-spatial       | 0.1056     | −5.5 (−11.3 to 0.65)        | −0.76       | 2.12  |
| Verbal function      | 0.0098a    | −21.95 (−44.85 to −6.15)    | −0.92       | 4.1335|
| Motor skills         | 0.0827     | −3.9 (−7.55 to −2.2)        | −0.52       | 0.85  |
| Chalder fatigue scale| 0.0059a    | 18 (9.5 to 26)              | 1.75        | 98.13 |

*significant difference between time points; BF = Bayes factor; CI = confidence interval; IPS = information processing speed.

Many patients are unable to work (either in manual or office-based roles), drive, participate in their usual physical activity or, at times, engage with their family in the manner they would wish. The treatment options available for such people with severe symptoms of long COVID are limited, with very few interventional options.

Here, to our knowledge, we describe the first evaluated use of HBOT to manage long COVID in the UK or internationally. We report statistically and clinically significant improvements to both the overall fatigue score and a range of cognitive domains using validated scales. The effect size measures calculated are large, suggesting a substantial improvement and, thus, there is a small likelihood that these results are due to chance despite the small initial sample size. These are important findings suggesting a possible positive effect of HBOT on the common long COVID-related symptoms of fatigue and ‘brain fog’. These results match with the clinical and qualitative observations of patients receiving the therapy, many of whom report their lives have been transformed.

The mechanism of long COVID is still uncertain.1 One possible hypothesis is that the wide variety of changes that characterise long COVID are a result of prolonged tissue hypoxia.4,5 This is frequently the common denominator for many diseases that are responsive to HBOT.11 Further research is needed to understand the underlying mechanisms of long COVID and positive responses seen in relation to HBOT.1

While these results are important, they represent only an initial evaluation. Indeed, the sample size consists of only 10 patients. Furthermore, these patients have not been followed up for a prolonged period to assess whether the noted improvements of these long COVID-related symptoms were sustained. Based on initial informal feedback, patients do excellently in the longer term. Thus, there is a need to assess these effects of HBOT in the context of a randomised placebo-controlled prospective study. However, these initial results suggest that HBOT merits further study as a treatment option for patients presenting with long COVID symptoms (such as fatigue). Given the scale of the emerging long COVID public health emergency globally, and the still ongoing COVID-19 pandemic, there is an urgent need for larger-scale randomised placebo-controlled trials to evaluate the potential impact of HBOT in the context of long COVID. In addition, creation of a registry of patients receiving HBOT for long COVID symptoms (such as fatigue) in order to obtain follow-up data over time is also suggested. These are both elements that will be necessary to maximise the benefits of HBOT for the management of long COVID.

|          | Before | After |
|----------|--------|-------|
| Chalder fatigue scale | 100 | 70 |
| Global cognition | 120 | 80 |
| Memory | 140 | 100 |
| Executive function | 160 | 120 |
| Attention | 180 | 140 |
| Information processing speed | 200 | 160 |
| Visual-spatial | 220 | 180 |
| Verbal function | 240 | 200 |
| Motor skills | 260 | 220 |
