Abstract

Background: Tracheoesophageal fistula (TEF) is a rare but life-threatening complication after esophagectomy. It has a high mortality rate and often leads to severe aspiration pneumonia. Various types of surgical repair procedures have been reported, but the optimal management of TEF is challenging and controversial. Treatment should be individualized to each patient.

Case presentation: A 66-year-old female underwent transthoracic esophagectomy with gastric tube reconstruction and an intrathoracic anastomosis for esophageal cancer. Three years later, she had hematemesis and was diagnosed with a gastro-aortic fistula due to a gastric ulcer. She underwent endovascular aortic repair urgently at another hospital. Two days later, she underwent total resection of the gastric tube, during which time an injury to the trachea occurred; it was repaired by patching the stump of the esophagus to the injury site. Two months later, descending aortic replacement was performed due to infection of the stent graft. Six months after the first operation, a TEF developed. The patient was referred to our hospital for further treatment. The fistula was ligated and divided via a cervical approach, and a pectoralis major muscle flap was used to cover the defect. Esophageal reconstruction with the pedunculated jejunum was performed via a subcutaneous route. The postoperative course was uneventful. The patient was discharged after 6 months of physical and dysphagia rehabilitation.

Conclusion: A TEF located near the cervicothoracic border was successfully treated with a pectoralis major muscle flap through a cervical approach. Total resection of a gastric conduit in the posterior mediastinum carries a risk of tracheobronchial injury; however, if such an injury occurs, surgeons should be able to repair the injury using a suitable flap depending on the injury site.

Keywords: Tracheoesophageal fistula, Gastric conduit ulcer, Pectoralis major muscle flap

Background

Tracheoesophageal fistula (TEF) is a rare but life-threatening complication after esophagectomy. It has a high mortality rate and often leads to severe aspiration pneumonia [1, 2]. Various types of surgical repair procedures have been reported, but the optimal management of TEF is challenging and controversial. Treatment should be individualized to each patient.

Herein, we report a patient with a TEF after total resection of a gastric conduit for gastro-aortic fistula due to a gastric ulcer, successfully repaired with a pectoralis major muscle flap through a cervical approach.

Case presentation

A 66-year-old woman with esophageal cancer underwent transthoracic esophagectomy with three-field lymph node dissection via a muscle-sparing thoracotomy as previously reported [3], with gastric conduit reconstruction and an intrathoracic anastomosis. A high-dose proton pump inhibitor (PPI) was administered postoperatively due to the patient’s history of gastric ulcers; she discontinued the...
medication of her own volition. Three years after surgery, she was admitted to a local hospital for mediastinitis due to a perforated gastric ulcer in the conduit (Fig. 1a). She was treated with antibiotics and fasting. Seventeen days later, she had hematemesis and was diagnosed with a gastro-aortic fistula due to a gastric ulcer (Fig. 1b, c). She was transferred to a nearby university hospital with shock status and underwent endovascular aortic repair urgently, using two GORE® TAG® devices (W.L. Gore & Associates, Flagstaff, AZ). Two days later, total resection of the gastric tube was performed via a right posterolateral thoracotomy. There was an abscess cavity between the gastric tube and the descending aorta which consisted of necrotic tissue and old blood. A 2-cm wall defect was found on the right wall of the middle of gastric tube. The clot-filled gastric tube was resected. The perforation of the descending aorta was left. During this operation, a tracheal injury occurred while the remnant esophagus was being separated from the trachea; this injury was subsequently repaired by patching the stump of the esophagus to the injury site. Tracheostomy and a feeding jejunostomy were also performed. The operative time was 8 h and 40 min, and the blood loss was 2380 ml. The remnant esophagus had been decompressed by nasal tube since the total resection of gastric conduit till the following reconstructive surgery. Two months later, a descending aortic replacement was performed due to infection of the stent graft. Stent graft was removed, and the descending aorta between the fifth vertebra and the eleventh vertebra level was replaced with rifampicin-soaked 24-mm J graft (JUNKEN MEDICAL, Tokyo, Japan). Infected vascular intima of the aorta around the gastro-aortic fistula was resected. The operative time was 8 h and 10 min. Purulent matter was found around the stent graft, and *Candida albicans* was recognized by the bacterial culture of the pus. Postoperative severe pneumonia due to methicillin-resistant *Staphylococcus aureus* (MRSA) occurred after aortic replacement and required artificial respirator. Postoperative pneumonia was gradually improved by antibiotics. Three months later, she was transferred to previous local hospital. When a TEF developed 6 months after the first operation, in spite of decompression of the remnant esophagus.

![Fig. 1](image)

**Fig. 1** a Gastrointestinal endoscopy showed an ulcerated lesion on the right wall of middle of gastric tube. b Horizontal and c sagittal enhanced computed tomography image showed an irregular ulceration on the anterior wall of the descending aorta, no extravasation, and absence of the descending aortic wall and gastric wall, suggesting sealed rupture of the descending aorta (yellow arrow).
by nasal tube, she still had required respirator due to prolonged postoperative pneumonia. Her poor general condition could not allow reconstructive surgery. She could withdraw from respirator 5 months after the aortic replacement (7 months after the first operation). Though she suffered from repeated bouts of aspiration pneumonia, she could walk after rehabilitation for 5 months (1 year after the first operation), and transferred to our hospital for reconstructive surgery. This patient’s time course is summarized in Fig. 2.

Bronchoscopy showed a fistula on the membranous portion of the trachea (Fig. 3a). Gastrointestinal endoscopy revealed a fistula in the stump of the esophagus (Fig. 3b). Computed tomography showed the TEF to be on the cervicothoracic border (Fig. 3c). The fistula was formed between the trachea and the esophageal stump on the cervicothoracic border (Fig. 3d). The cervical esophagus was accessed through a cervical approach, and the fistula was ligated and divided (Fig. 4a, b). A pectoralis major muscle flap was used to cover the defect and lay under the trachea (Fig. 4c, e). Esophageal reconstruction using the pedunculated jejunum with a microvascular anastomosis was performed via a subcutaneous route (Fig. 4d, e). The total operative time was 8 h.
and 54 min. Intraoperative blood loss was 453 ml. The postoperative course was uneventful. She was transferred to the previous hospital on postoperative day 14 and was discharged after 6 months of physical and dysphagia rehabilitation.

**Discussion**

In patients with TEF after esophagectomy, the latissimus dorsi muscle is the easiest muscle from which to fashion a flap for coverage, but it is often not usable as it is transected in a posterolateral thoracotomy. Though various repair techniques have been reported, the choice of which muscle to use for the repair depends on the location of the fistula. A pedicled posterior pericardial flap or diaphragmatic flap is useful for a fistula located near the carina or near a peripheral bronchus [4, 5]. A pectoralis major muscle flap or sternocleidomastoid muscle flap is useful for a fistula near or in the neck [6, 7]. The intercostal muscle flap can usually reach the whole intrathoracic trachea and bronchus and is a highly versatile option [8].

In this patient, there were several complicating factors including the surgical approach to the TEF given dense adhesions with two prior thoracotomies, flap choice, and

a Cervical incision line.

b The cervical esophagus was accessed through a cervical approach, and the fistula was ligated (white arrow).

c A pectoralis major muscle flap was fixed to the fistula site, underneath the trachea. Pectoralis major muscle flap under the trachea (white arrow).

d Esophageal reconstruction using the pedunculated jejunum with a microvascular anastomosis was performed via a subcutaneous route.

e A schema of the operation.
The frequency of peptic ulcer in the reconstructed mastoid muscle flap could also have been an option as the gosotomy. A pectoralis major muscle flap or a sternocleidomastoid muscle flap or a sternocleidomastoid muscle flap would have been a good option for repair of the initial tracheobronchial injury. When the tracheal injury occurred, the surgeons should have created an intercostal muscle flap to repair the injury using a suitable flap depending on the injury site.

Conclusions
A TEF located near the cervicothoracic border was successfully treated with a pectoralis major muscle flap through a cervical approach. Because total resection of a gastric conduit in the posterior mediastinum carries a risk of tracheobronchial injury, thoracotomy with creation of an intercostal muscle flap should be performed in preparation for a tracheobronchial injury in such situations. If such an injury occurs, surgeons should be able to repair the injury using a suitable flap depending on the injury site.

PPI: Proton pump inhibitor; SCM: Sternotomoesophageal mastoid muscle; TEF: Tracheoesophageal fistula

Authors’ contributions
MF, YS, HF, KI, and YK performed the surgery. YS and HF took charge of postoperative care in our hospital. AH took charge of conservative therapy for mediastinitis due to a perforated gastric ulcer in the conduit and postoperative physical and dysphagia rehabilitation in the local hospital. YS prepared the manuscript. MF and MN assisted in drafting the manuscript and reviewed the article. All authors read and approved the final manuscript.

Ethics approval and consent to participate
This study was carried out in accordance with the principles of the Declaration of Helsinki.

Consent for publication
Written informed consent was obtained from the patient for publication of this case report and any accompanying images.

Competing interests
The authors declare that they have no competing interests.

Publisher’s Note
Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.
