Summary
The nitrogen species available in the growth medium are key factors determining expression of xyl genes for biodegradation of aromatic compounds by Pseudomonas putida. Nitrogen compounds are frequently amended to promote degradation at polluted sites, but it remains unknown how regulation observed in the test tube is propagated into actual catabolism of, e.g. m-xylene in soil, the natural habitat of this bacterium. To address this issue, we have developed a test-tube-to-soil model system that exposes the end-effects of remediation practices influencing gene expression of P. putida mt-2. We found that NO3− compared with NH4+ had a stimulating effect on xyl gene expression in pure culture as well as in soil, and that this stimulation was translated into increased m-xylene mineralization in soil. Furthermore, expression analysis of the nitrogen-regulated genes amtB and gdhA allowed us to monitor nitrogen sensing status in both experimental systems.

Hence, for nitrogen sources, regulatory patterns that emerge in soil reflect those observed in liquid cultures. The current study shows how distinct regulatory traits can lead to discrete environmental consequences; and it underpins that attempts to improve bioremediation by nitrogen amendment should integrate knowledge on their effects on growth and on catabolic gene regulation under natural conditions.

Introduction
Approaches used in environmental biotechnology to bring about pollutant degradation, i.e. bioremediation, rely on the activities of catabolic microorganisms in complex environments. In their natural habitat, these microorganisms encounter numerous exogenous factors that can affect their growth and general metabolic activity, and even their ability to express specific genes involved in pollutant degradation (de Lorenzo, 2008). Hence, the impact of environmental factors on catabolic microorganisms is of paramount significance for the optimal exploitation of specific degrader microorganisms in bioaugmentation, where microorganisms selected for catabolic performance under laboratory conditions are brought back into their natural habitat.

However, how these properties are regulated by microorganism in the environment is at present not clear (Meckenstock et al., 2015).

Pseudomonas putida mt-2, which carries the catabolic TOL plasmid, pWW0, enabling m-xylene and toluene degradation is a safe and well-studied paradigm organism for applications in bioaugmentation (de Lorenzo et al., 2013). The catabolic xyl genes on pWW0, which are involved in m-xylene and toluene degradation, are organized in the upper and lower/meta TOL pathway operons (Fig. 1). The significance of environmental factors for xyl gene expression has been intensively studied in pure culture model systems (Velázquez et al., 2006; Del Castillo and Ramos, 2007). Some of these studies have revealed that nitrogen sources, e.g. NH4+ and NO3−, influence xyl gene expression in mt-2 (Velázquez et al., 2006; Huang et al., 2008). Expression of xyl genes of the upper TOL pathway is regulated by the sigma factor, σ54, which was initially identified as a...
Nitrogen regulates xyl gene expression in soil

---

**Fig. 1.** Degradation of *m*-xylene and organization of the *xyl* structural and regulatory genes of the TOL pathway on pWW0. Enzymes of the upper pathway catalyse the sequential oxidation of one methyl group of *m*-xylene resulting in 3-methyl benzoate (3MB), which is further converted to tricarboxylic acid cycle intermediates by enzymes encoded in the *meta* pathway operon. Six promoters are involved in the expression of the two catabolic gene clusters. Transcription of the upper pathway is initiated from the σ^54-dependent promoter Pu, while the meta pathway is transcribed from Pm that requires either σ^32 (σ^n) or σ^38 (σ^m). Furthermore, two regulatory proteins, XylR and XylS, are involved in the tightly controlled expression of the entire TOL pathway that additionally requires the presence of specific effector molecules, *m*-xylene and 3MB, and the chromosomal-encoded HU and IHF proteins. The master regulator XylR, encoded by the xylR gene, is transcribed from two σ^70-dependent tandem promoters, and is involved in activation of Pu and the σ^54-dependent Ps1 promoter of xylS, encoding the meta pathway regulator, XylS. In addition, xylS is constitutively expressed from the σ^54-dependent promoter Ps2. The two catabolic genes employed as proxies of TOL pathway expression in this study, xylM and xylE from the upper and meta pathway, respectively, are shown in bold.

---

Nitrogen specific sigma factor (Ramos et al., 1997; Cases et al., 2003). Hence, this global regulator might modulate substrate-specific induction of the TOL pathway in response to altered environmental conditions caused by the nitrogen supplements (Commichau et al., 2006; Hervás et al., 2009).

Nitrogen is an important limiting element for bacterial growth in many environments, in particular at hydrocarbon contaminated sites (van Veen et al., 1997; Jensen and Nybroe, 1999; Walecka-Hutchison and Walworth, 2006), and several studies on bioremediation of hydrocarbon contaminated soils and sediments have shown the significance of inorganic nitrogen amendments for *in situ* pollutant biodegradation (Lindstrom et al., 1991; Davis and Madsen, 1996; Aislabie et al., 2012). The chosen source of nitrogen to add in bioremediation studies is NH₄⁺ that can be taken up and assimilated directly by the bacterial degraders (Walecka-Hutchison and Walworth, 2006; Komilis et al., 2010). Hence, it becomes of interest whether the different effects of NH₄⁺ and NO₃⁻ on catabolic gene expression by *P. putida* mt-2, which have been revealed by well-controlled pure culture conditions, where typically one parameter was changed at a time (Velázquez et al., 2006; Hervás et al., 2008) manifest also in a complex environmental context (de Lorenzo, 2008). An additional, unsettled issue is how tightly changes in xyl gene expression are coupled to the functional outcome of the pathway, i.e. changes in *m*-xylene biodegradation in a soil system.

The objective of current study was to address whether the test tube effects of nitrogen on catabolic gene expression by *P. putida* mt-2 propagate into an actual environmental scenario. To this end we established an experimental model system allowing us to compare the effect of specific nitrogen sources (NH₄⁺ vs. NO₃⁻) on the transcriptional dynamics of *P. putida* mt-2 catabolic *xyl* genes in pure culture and after introduction to natural soil with different nitrogen regimes. In either systems, we focused on expression of xylM and xylE of the upper and lower TOL pathway, respectively, as the enzyme products of these two genes are regarded as key enzymes in the biodegradation of toluene and *m*-xylene (Hendrickx et al., 2006; Martinez-Lavanchy et al., 2010). In addition, sensing of the nitrogen status by *P. putida* mt-2 cells was compared for pure culture and soil systems through expression of the *amtB* and *gdhA* genes signalling NH₄⁺ deficiency and surplus respectively (Hervás et al., 2008). The system further allowed us to examine whether changes in gene expression in soil were translated into actual variations in biodegradation performance.

**Results**

**Nitrogen source impact on expression of xylM and xylE in pure culture**

Initially, we performed a detailed analysis of the temporal dynamics of xylM and xylE expression for exponentially growing *P. putida* mt-2 incubated with *m*-xylene and either NH₄⁺ or NO₃⁻ as nitrogen source. NH₄⁺ had an initial stimulating effect on xylM expression compared with NO₃⁻ (P = 0.006) within the first hour after shifting the nitrogen source (Fig. 2). However after 3–5 h, the expression pattern shifted, and while xylM expression in...
NH$_4^+$ medium decreased, a delayed expression peak in NO$_3^-$ medium was observed. Hence after 5 h, expression of xylM in NO$_3^-$ medium was significantly higher than expression in NH$_4^+$ medium ($P = 0.027$). In contrast, we observed no difference in xyle expression between the two treatments until after 3 h (Fig. 2). At this time, NO$_3^-$ stimulated xyle expression compared with NH$_4^+$, and after 5 h the difference to expression in NH$_4^+$ medium was statistically significant ($P = 0.015$). Cultures in NH$_4^+$ medium as well as cultures in NO$_3^-$ medium reached stationary phase after 1–3 h according to qPCR quantification of xylM and xylE copy numbers (data not shown). Hence, the differences in expression levels were not related to differences in growth phase between cultures.

Expression of the nitrogen-regulated genes amtB and gdhA, encoding a high-affinity NH$_4^+$ transporter expressed during NH$_4^+$ limitation, and glutamate dehydrogenase, reported to be highly expressed in the presence of NH$_4^+$, respectively (Hervás et al., 2008), was measured to determine whether the two nitrogen sources were perceived differentially by the cells (Fig. 3). In cultures incubated with NO$_3^-$, amtB expression was initially more than 100-fold higher than in cultures incubated with NH$_4^+$ as nitrogen source. The amtB expression then declined but remained significantly higher than for cells incubated in NH$_4^+$ medium for at least 7 h (Fig. 3, insert). In contrast, gdhA expression initially peaked for cells shifted from a spent to a fresh NH$_4^+$ medium, but remained low for cells grown with NO$_3^-$.

The expression of gdhA hereafter decreased to a low and steady level that remained highest ($P < 0.05$) for cells cultured with NH$_4^+$ throughout the entire sampling period.

In conclusion, the nitrogen sources impact xyl gene expression in this pure culture system with NO$_3^-$ having

**Fig. 2.** Transcriptional dynamics of xylM and xyle by *P. putida* mt-2 incubated in the presence of m-xylene vapours in M9 medium with either 10 mM NH$_4^+$ (green) or 10 mM NO$_3^-$ (red) as sole N-source. Samples were withdrawn between 15 min and 7 h after the shift in N-source. Data are mean values of mRNA normalized to DNA copies of the corresponding genes from triplicate cultures, and error bars represent standard error of mean.

**Fig. 3.** Transcriptional dynamics of the N-regulated genes gdhA and amtB by *P. putida* mt-2 incubated in the presence of m-xylene vapours in M9 medium with either 10 mM NH$_4^+$ (green) or 10 mM NO$_3^-$ (red) as sole N-source. Insert in the right panel shows expression of amtB after 2–7 h on the same scale as expression of gdhA. Data are mean values of mRNA normalized to DNA copies of the corresponding genes from triplicate cultures, and error bars represent standard error of mean.
a delayed, but overall stimulating effect compared with NH₄⁺. Furthermore, the expression of *amtB* and *gdhA* provided information on the NH₄⁺ availability to *P. putida* mt-2, and we consequently transferred this monitoring system for use in subsequent soil experiments.

**Response of *P. putida* mt-2 to changing nitrogen-conditions in soil microcosm**

A soil microcosm was established in which nitrogen limitation was brought about by pre-incubation with ground barley straw (Jensen and Nybroe, 1999) so that the influence of added nitrogen sources could be addressed with minimal interference from indigenous nitrogen pools. After incubation with straw for 7 days, the soil contained ~0.1 mmol kg⁻¹ soil of water soluble NO₃⁻ and NH₄⁺ as determined by chemical analyses. This soil is referred to as N-limited soil hereafter. *P. putida* mt-2 was then introduced to the N-limited soil and exposed to *m*-xylene. Nitrogen in the form of NaNO₃ or NH₄Cl was added to reach a concentration of 10 mmol kg⁻¹ soil respectively. The pH of the NH₄⁺-amended soil (pH 6.5) at the end of the 46-h incubation period.

Addition of NO₃⁻ to the N-limited soil gave rise to an increase in expression of *amtB* compared with that seen for the N-limited soil supplemented with NH₄⁺ (Fig. 4). Expression peaked at 8–10 h incubation, i.e. later than in liquid culture (Fig. 3), and after 12 h, *amtB* expression was again downregulated; nonetheless, the expression lasted longer than in liquid culture. In contrast, *gdhA* expression was strongly upregulated in the N-limited soil receiving NH₄⁺, but only increased slightly from the background level in NO₃⁻-amended soil (Fig. 4). Downregulation of *gdhA* in NH₄⁺-amended soil also appeared, but the downregulation occurred slightly later than the downregulation of *amtB* in NO₃⁻-amended soil. The levels of *amtB* and *gdhA* expression were comparable, which contrast the ~20-fold higher expression of *amtB* than *gdhA* in pure culture (compare Figs 3 and 4).

In conclusion, sources of inorganic nitrogen in the soil directly affect expression of the selected indicator genes involved in nitrogen uptake and transformations. Although the expression patterns were not identical to those recorded for *P. putida* mt-2 in liquid culture, they reveal that soil amended with NO₃⁻, unlike soil amended with NH₄⁺, is perceived as being NH₄⁺ deficient by the introduced cells.

**Nitrogen source impact on expression of xylM and xylE and on *m*-xylene mineralization in soil**

In soils receiving NO₃⁻, expression of xylM and xylE peaked after 10 h of incubation, while the expression peaks in NH₄⁺-amended soils appeared slightly delayed after 12 h (Fig. 5). The NO₃⁻ amendment resulted in higher expression of both xyl genes in the ascending part of the expression curves. For xylM the expression was significantly (*P* = 0.044) higher (approximately two-fold) in NO₃⁻-amended soil when comparing the peak after 10 h with the peak after 12 h in the NH₄⁺-amended counterpart. For xylE, there was nevertheless only a tendency towards a higher expression peak in the NO₃⁻-amended soil (*P* = 0.30).

Compared with observations made for pure cultures, the initial stimulatory effect of NH₄⁺ on xylM expression was not seen in soil, and there was a delay in the stimulatory effect on xylM and xylE expression exerted by NO₃⁻ (compare Figs 3 and 5). Importantly, the higher xyl gene expression in NO₃⁻-amended soils was reflected in a significantly (*P* = 0.047) higher mineralization of *m*-xylene after 21 h and onwards when compared with soils amended with NH₄⁺ (Fig. 5). In N-limited soil conditions, xylM and xylE expression were comparable, but the downregulation occurred slightly later than the

![Fig. 4](image-url) Dynamic of expression of the N-regulated genes *gdhA* and *amtB* by *P. putida* mt-2 inoculated into N-limited soil amended with 10 mmol kg⁻¹ soil NH₄⁺ or NO₃⁻. Data are mean values of mRNA normalized to DNA copies of the corresponding genes from triplicate soil setups, and error bars represent standard error of mean.
that did not receive NO$_3^-$ or NH$_4^+$, the mineralization did not differ from mineralization in NH$_4^+$-amended microcosms (data not shown).

In the current experiment, *P. putida* mt-2 was introduced to a natural soil that may contain indigenous xylene mineralizing populations carrying *xyl* genes. To determine the extent to which these populations contributed to our expression and mineralization analyses, we showed that the soil contained less than 10$^3$ copies g$^{-1}$ soil of *xyl* genes. Finally, mineralization analysis in soil microcosm without inoculated mt-2 cells revealed that mineralization by indigenous *m*-xylene-degrading soil bacteria accounted for a minor part (~10%) of $^{14}$C-CO$_2$ build up (data not shown). Consequently, *m*-xylene mineralization could be ascribed to the inoculated *P. putida* mt-2 cells.

In conclusion, *xyl* gene expression by *P. putida* mt-2 in soil was stimulated more by NO$_3^-$ than by NH$_4^+$. The same was observed for liquid cultures, however with a different temporal expression pattern. Importantly, the changes in *xyl* gene expression in response to the different nitrogen sources served as descriptors of corresponding changes in *m*-xylene mineralization in the soil system.

**Discussion**

Environmental conditions affecting *xyl* gene expression by *P. putida* mt-2 introduced to soil has to the best of our knowledge not previously been clarified. In complex soil environments, introduced degrader bacteria are exposed to a variety of biotic and abiotic stress factors, which might not resemble situations tested individually under standard liquid culture conditions. At the current time, it remains obscure how bacterial metabolism is regulated in their natural habitat (Meckenstock *et al.*, 2015), and whether regulatory concepts derived from liquid culture studies (Duetz *et al.*, 1996; Commichau *et al.*, 2006; Hervás *et al.*, 2008; Pfüger-Grau and Görke, 2010) are valid for catabolic bacteria exposed to the plethora of challenging conditions in their natural environment. Hence, the current study integrates experiments in a pure culture system and a soil model system. Importantly, our analyses couples changes in *xylM* and *xylE* gene expression to changes in the output of the catabolic pathway in question, *m*-xylene biodegradation, as transcript abundance and their cognate processes is often not correlated under environmental conditions (Rocca *et al.*, 2014).

Our results on *xyl* gene regulation by nitrogen sources in pure culture expand the results of Velázquez and colleagues (Velázquez *et al.*, 2006), who determined *xyl* gene expression by microarray technology and by Huang and coworkers (Huang *et al.*, 2008), who detected increased *Pu* promoter activity with NO$_3^-$ as nitrogen source at single time points. Interestingly, the stimulation of *xyl* gene expression by NO$_3^-$ observed in the current study occurred later than in previous studies emphasizing the importance of monitoring temporal dynamics of gene expression.

NH$_4^+$ is considered the preferred nitrogen source for bacteria, as its assimilation is less energy-expensive as

Fig. 5. Transcriptional dynamics of *xylM* and *xylE* (two upper panels), and mineralization of *m*-xylene (lower panel) in N-limited soil amended with 10 mmol kg$^{-1}$ soil NH$_4^+$ or NO$_3^-$, Gene expression data are mean values of mRNA normalized to DNA copies of the corresponding genes from triplicate soil set-ups, and error bars represent standard error of mean. Mineralization data are mean values from triplicate soils and error bars represent standard error of mean.
Nitrogen regulates xyl gene expression in soil

To monitor the availability of NH₄⁺ that first needs conversion into NH₄⁺ before it is assimilated via glutamine synthetase–glutamate synthase (Magasanik, 1993; Merrick and Edwards, 1995; Leigh and Dodsworth, 2007). The physiological change following substitution of NH₄⁺ with NO₃⁻ might consequently be due to introduction of a poor nitrogen source, although Velázquez et al. (2006) noted only a weak induction of indicator genes for nitrogen starvation stress in P. putida mt-2 exposed to NO₃⁻. To monitor the availability of NH₄⁺ to mt-2 cells, we quantified the expression of two genes, amtB and gdhA that are under control of the major nitrogen-associated transcriptional regulator, NtrC. The amtB gene encodes a high-affinity NH₄⁺ transporter. It belongs to the NH₄⁺ transport family of proteins ubiquitous to all bacteria, and is blocked under conditions of nitrogen excess (Coulls et al., 2002; Javelle and Merrick, 2005; Leigh and Dodsworth, 2007). Expression of amtB in P. putida is stimulated under nitrogen limiting conditions established, e.g. during growth on serine (Hervás et al., 2008; Yeom et al., 2010). The glutamate dehydrogenase gene, gdhA, on the other hand is reported to be expressed under conditions of normal nitrogen access and is actively repressed by nitrogen limitation in P. putida (Hervás et al., 2010). Our observation of high amtB and very low gdhA expression in NO₃⁻-amended cultures over the entire time-course examined here indicates that mt-2 sensed this medium as being NH₄⁺ deficient. The opposite pattern recorded during growth with NH₄⁺ demonstrates that, in concert, amtB and gdhA function as indicators for the cellular nitrogen status. Interestingly, the expression of amtB and gdhA is highly dynamic within 1–3 h where after expression is down-regulated to a steady level likely because the nitrogen fluxes have reached balance. Peaks in expression have previously been observed, e.g. for the Cupriavidus pinatubonensis tfdA gene involved in herbicide catabolism just after exposure to the substrate, and for the P. putida catalase gene katA just after exposure to hydrogen peroxide (Svenningsen et al., 2015 and unpublished observations). We speculate that a pool of enzymes is produced during the burst in gene expression that is able to carry out the requested function for an extended time period. Again, our data underline that data obtained from sampling at single timepoints in gene expression studies might lead to incorrect conclusions.

To be able to assess the nitrogen source impact on m-xylene biodegradation in soil, we reduced the readily accessible soil nitrogen pool through incubation with barley straw. Due to a C:N ratio higher than the average bacterial C:N ratio, this treatment immobilizes nitrogen in non-sterile soil (Geisseler et al., 2010). The expression of the two nitrogen-regulated genes amtB and gdhA showed initial peaks as discussed above for liquid cultures. However, the response was slower and we also noted subtle differences in induction levels between pure cultures and soil that could be explained by the NH₄⁺ levels in the two systems. Hence, the weaker induction of amtB in NO₃⁻-amended soil than in liquid NO₃⁻-amended medium as well as the weak induction of gdhA in NO₃⁻-amended soil suggest that small amounts of an easily available nitrogen source were available in the soil. Indeed, chemical analysis showed that the nitrogen-limited soil still contained 0.1 mmol kg⁻¹ of water soluble NH₄⁺ after the straw pre-treatment. This NH₄⁺ pool has been available even to the cells introduced to NO₃⁻-amended soils. Hence, our results indicate that mt-2 cells are able to sense and respond to indigenous nitrogen pools in the soil, and they demonstrate that the amtB and gdhA genes are valid indicator genes for studying the bioavailability of NO₃⁻ versus NH₄⁺ to P. putida mt-2 in natural soil.

The higher expression of xyl genes in response to m-xylene in NO₃⁻-amended than NH₄⁺-amended soil was in general agreement with observations made for pure cultures. Obviously, xyl gene induction in the soil was slower than in liquid culture. This might be caused by sorption of m-xylene to soil organic matter. However, the slower response was even recorded for expression of genes involved in nitrogen metabolism as discussed above. Hence, the delay might be ascribed to the down-shift that the cells experience upon transfer to the oligotrophic soil environment (van Veen et al., 1997; Koch et al., 2001) with a high complexity of potential stressors (including the m-xylene carrier hexane) that the cells need to deal with (Daurabas and Chakrabarty, 1992; Velázquez et al., 2006). Importantly, the robustness of our gene expression system permitted us to relate small differences in gene expression in soil under the two nitrogen regimes to a significant difference in total mineralization of the added m-xylene. This is important because discrepancy between the amounts of transcripts and their corresponding protein abundance and functional activity is occasionally observed (Poblete-Castro et al., 2012). Regulation of gene expression is the first and most direct cellular response to changed environmental conditions in prokaryotes. We indeed observed that xyl gene induction preceded m-xylene mineralization in soil, probably reflecting the time required for establishing a pool of catabolic enzymes in the cells. Comparable time-courses have been observed for tfdA gene expression and MCPA herbicide mineralization by C. pinatubonensis introduced to soil (Nicolaisen et al., 2008). When combined with ¹⁴C-mineralization assays, we suggest that xyl transcript analysis provides robust insight into factors controlling m-xylene biodegradation, but for future studies proteome analyses of the catabolic enzymes could be of considerable interest.
It remains to be clarified exactly how nitrogen status affect xyl gene expression. The upper TOL pathway promoter Pnu as well as the Ps1 promoter of the meta pathway transcriptional regulator XylS are controlled by the sigma factor, σ^54, encoded by the rpoN gene (Ramos et al., 1997; Cases et al., 2003; Shingler, 2003) (Fig. 1). Velázquez and coworkers (Velázquez et al., 2006) proposed that NO3^-- could increase xyl gene expression by a mechanism involving stimulation of the two σ^54 dependent TOL pathway promoters by increasing the amount of σ^54-bound core RNA polymerases; a condition that might occur during assimilation of NO3^-- derived NH4^+ through glutamine synthetase–glutamate synthase (Moreno-Vivián et al., 1999; Velázquez et al., 2006). An alternative mechanism suggested by Aranda-Olmedo et al. (2005) is that the nitrogen phosphotransferase system, PTS^Ntr, involved in nitrogen metabolism (Pfüger-Grau and Görke, 2010), also interferes with activation of the σ^54-dependent TOL pathway promoters via their effector molecules; hence, this mechanism is more related to the interplay between nitrogen starvation/metabolism and carbon metabolism. The observation that xylene mineralization was comparable in natural soil and nitrogen-depleted soil amended with NH4^+ might suggest that the higher mineralization in NO3^-amended soils is a direct response to NO3^--. However, to the best of our knowledge, a NO3^-sensing mechanism has not been described for P. putida.

The current methodological approach allowed us to gain insight into regulation of catabolic gene expression of P. putida mt-2 by environmental factors under close-to-natural soil conditions. Although temperature and water content were kept constant, the mt-2 cells introduced to a natural soil would be confronted with some spatial heterogeneity, with possible competition or collaboration from indigenous microorganisms, and with realistic indigenous pools of carbon sources and nutrients. Our study underscores that global regulation of catabolic genes acts beyond direct substrate induction. Furthermore, regulatory patterns emerge in our soil model systems that are comparable to those observed in liquid cultures. Nevertheless, we even observe noteworthy differences in terms of temporal dynamics and induction levels. Interestingly, we have seen that environmental regulation of xyl genes in pure culture does not correspond to regulation in soil, when changing the available carbon sources (NB Svenningsen, unpublished results). Hence, more effort could be devoted to deciphering the environmental factors that affect expression of these genes in the soil.

With the current model system in hand, we have a good basis for investigating the ‘behaviour’ of P. putida mt-2 under realistic conditions in different soils and considering other stressors that could influence the potential for biodegradation. From both a basic and an applied perspective, it is a key issue to understand the in situ environmental conditions able to stimulate the biodegradative potential of a particular organism (Cases and de Lorenzo, 2005). Although the specific nitrogen sources available for inoculated degrader bacteria will influence their growth potential, and therefore the potential for pollutant degradation on the long run, our data show that specific nitrogen sources in soil also affect the expression of catabolic genes of degrader bacteria. Hence, we suggest that attempts to improve bioremediation of pollutants from contaminated sites should integrate knowledge on environmental effects on growth as well as on catabolic gene regulation under natural conditions.

Experimental procedures

Bacterial strain and growth conditions

_Pseudomonas putida_ mt-2 harbouring the TOL plasmid, pWW0 (Greated et al., 2002) that enables it to degrade among others toluene, m- and p-xylene, was obtained from Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH, Braunschweig, Germany (DSM-6125). For all experiments, the strain was pre-cultured over night at 28°C with agitation at 150 r.p.m. in M9 minimal medium (6.0 g L^-1 Na₂HPO₄, 3.0 g L^-1 KH₂PO₄, 0.5 g L^-1 NaCl, 1.0 g L^-1 NH₄Cl, 0.25 g L^-1 MgSO₄·7 H₂O, 0.015 g L^-1 CaCl₂·2 H₂O) supplemented with 5 mM Na-succinate. For pure culture experiments, the overnight cultures were diluted in fresh M9 medium as specified in following section.

For soil experiments, cultures were harvested by centrifugation (5000 g, 5 min, 21°C), and cells were subsequently washed twice and re-suspended in 1 x phosphate-buffered saline (PBS). Cell densities were calculated based on measurements of optical density at 600 nm with OD = 1 corresponding to 10⁹ cells ml⁻¹ measured by standard CFU counting on LB agar.

Liquid culture experiment and sampling for nucleic acid extraction

Overnight cultures of _P. putida_ mt-2 in M9 medium (OD₆₀₀nm ~0.8) were diluted 100 times in fresh medium and exposed to vapours of m-xylene (Sigma-Aldrich, St. Louis, MO, USA) stemming from a 1:5 dilution in dibutyl phthalate (Sigma-Aldrich) in sealed flasks, basically as described in Velázquez et al. (2006). At OD₆₀₀nm ~0.5, cells were washed twice in PBS before resuspending them in N-free M9 medium supplemented with either 10 mM NO₃^- or NH₄^+ as nitrogen source and incubated in the presence of m-xylene at 28°C with agitation at 150 r.p.m. The bottles were sealed and kept closed during the incubation. At 15 min, 30 min, 1, 3, 5 and 7 h
Nitrogen regulates xyl gene expression in soil

Nitrogen regulates xyl gene expression in soil

Agricultural soil was collected from the Ap horizon (0–34 cm) of a soil profile located 20 km west of Copenhagen at 55°40' N and 12°18' E on the experimental farm Rørrendegård of Copenhagen University. The soil was stored in closed containers at 4°C until use. A subsample of soil was used for soil characterization. The soil pH was 6.8, determined in a 1:1 soil–water suspension. The particle size distribution was 22% clay, 13% silt, 29% course sand and 36% sand. The moisture content was set up to test for if the soil itself stimulates induction of the xyl genes in soil.

In addition to the treatments described above, a control soil microcosm without inoculation of mt-2 cells, plus addition of m-xylene was prepared to test for background mineralization of m-xylene and direct capture of 14C m-xylene in NaOH traps. Furthermore, a control with inoculation of mt-2 cells but without addition of m-xylene was set up to test for if the soil itself stimulates induction of the xyl genes in soil.

Additionally, at the beginning and in the end of incubation, soil water samples were collected for determination of pH and concentrations of NH4+ and NO3− associated to soil water (i.e. the directly bioavailable part). This was done by vortexing 0.15 g soil with 1.5 ml MilliQ water, followed by 1 h of shaking at 200 r.p.m. Finally, samples were centrifuged (10,000 g, 5 min) and analyses of pH and concentrations of NO3− and NH4+ were conducted on the supernatants.

Nucleic acid extraction and quantitative PCR

For extraction of nucleic acids from pure culture samples, the AllPrep DNA/RNA Mini Kit (Qiagen, Manchester, UK) was used according to the manufacturer’s protocol with addition of a lysozyme pre-treatment step at room temperature for 20 min (100 ng of random hexamer primers (Promega), 4 U of DNase-treated control reactions were prepared with DNA contamination. RT reactions were prepared with 400 ng of random hexamer primers (Promega), 4 U of RNase-free DNase 1 (Promega, Nacka, Sweden) according to the manufacturer’s protocol. cDNA was synthesized immediately thereafter by using 2 µl subsamples of each DNase-treated extract as template for reverse transcription (RT) with the Omniscript RT Kit (Qiagen). DNase-treated control reactions were prepared in parallel for RNA samples without addition of the reverse transcriptase (RT) to ensure the absence of DNA contamination. RT reactions were prepared with 400 ng of random hexamer primers (Promega), 4 U of SUPER RNase inhibitor (Ambion, Austin, TX, USA) and reagents provided in the kit for a final volume of 20 µl. Incubation conditions were followed as recommended by
the manufacturer. Resulting cDNA samples were stored at −20°C until use in qPCR.

Previously published primers were used to quantify the expression of *xylM*, *xylE* (Martínez-Lavanchy et al., 2010), *amtB* and *gdhA* (Hervás et al., 2008). qPCR reactions were prepared in 20 μl with 10 μl Brilliant II SYBR Green QPCR Master mix (Stratagene, La Jolla, CA, USA), 0.3 μM of each primer and 1 mg ml⁻¹ BSA. Thermal cycling conditions were following: an initial cycle of 95°C for 10 min, followed by 40 cycles of 95°C for 30 s, primer annealing at the temperatures stated in (Hervás et al., 2008; Martínez-Lavanchy et al., 2010) for 45 s and an elongation step at 72°C for 1 min. Subsequently a melting curve was run. All cDNA and DNA samples were diluted 1:10 before the qPCR. To check for possible contamination of RNA samples by genomic DNA, diluted samples of RNA were analysed by qPCR as well. Ct values for pure culture samples were related to a standard curve prepared from 10-fold dilutions of DNA extracted from 1 ml of liquid culture with OD₆₀₀nm of 0.8. For soil samples, a standard curve was prepared by inoculation of 10¹⁻¹⁰⁶ *P. putida* mt-2 cells per gram soil and subsequently extracting the DNA. Soil without inoculation of mt-2 cell had a natural background of *xyl* genes; hence, the standard curve was not linear below 10⁴ gene copies per gram of soil. From the slope of the standard curves, the amplification efficiencies of the qPCRs were calculated using the formula \( E = 10^{(-1/slope)} - 1 \); for all four gene amplified, the efficiencies were in the range 98–106%. Gene expression was calculated as mRNA normalized per DNA copy numbers as previously described (Nicolaisen et al., 2008), taking dilution steps from the DNase-treatment and RT into consideration when calculating mRNA numbers from the cDNA numbers. DNA and cDNA samples from the soil qPCRs were randomly chosen for Sanger sequencing to verify that the primers only targeted specific products in the soil.

**Statistical analysis**

All experiments were repeated independently at least twice, with each independent experiment involving triplicate samples. Mean values of such triplicates from one representative experiment are reported ± standard error of mean. Statistical significance was tested with Student’s t-test using the software PAST3.10 (University of Oslo, Norway). Data were considered significant when \( P < 0.05 \).

**Acknowledgement**

We thank Birgitte B. Rasmussen for technical assistance.

**Conflict of interest**

The authors have no conflict of interest.
